Standing in sharp contrast to the transactional model is *transformational leadership*, which along with *instructional leadership*, are seen by some researchers as having been playing the lead role in technology integration since 1990 (Hallinger 2007, as cited in Seyal 2015 p. 39). The transformational leaders, according to Yukl (1998) (as cited in Seyal 2015, p. 35), define the needs for change, create new visions, and work on acquiring their followers' commitment to the organization's vision and objectives through developing their self-motivation; coaching and empowering them; and inspiring them to transcend their self-interests and pursue instead higher-order goals aligned with the organization's set direction. In their actions, transformational leaders, therefore, are characterized by inspired motivation or charisma, individualized consideration, and intellectual stimulation; they use emotions to encourage staff to pursue the articulated shared goals, show personal interest in and provide support for employees and their development, and encourage innovative thinking and foster creativity and rational problem-solving (Bass 1985 as cited in Seyal 2015, p. 34). One more dimension of transformational leadership is idealized behavior, which relates to acting and integrity. What this refers to is that transformational leaders believe in, and demonstrate, self-control, high moral judgement, optimism, and self-efficacy. "They are strong believers of moral and ethical consequences of their actions" (Seyal 2015, p. 39). This idealized behavior on the part of the transformational leaders is what makes their followers respect and trust in their vision, especially in times of change and adoption of something new (Seyal 2015), such as a new technology tool or practice – just like what takes place in the process of integrating technology for teaching and learning purposes. For this reason, researchers (e.g., Daughtry and Finch 1997; Schepers et al. 2005; Seyal 2007) have concluded that transformational leadership style is a good fit for ICT integration in education; their study results collectively indicated that such a type of leadership is capable of promoting a culture of technological

innovation, of positively influencing perceived usefulness of technology, and of effectively facing challenges of technology (Seyal 2015, p. 35). Not only that, transformational leadership is capable also of moving others toward accomplishing more than what is usually expected of them (Northouse 2010 as cited in Seyal 2015). Still, however, a word of caution is needed here; despite the attractiveness of this type of leadership model, it is not totally free of limitations. For, as Bush (2011) warns, "it may be used as a vehicle for the manipulation or control of teachers who are required to support the 'vision' and aims of the leader" (p. 202).

Like the transformational style, instructional leadership is also considered as suitable for educational technology, primarily due to its focus on the prime purpose of educational institutions, which is teaching and learning (Bush 2011). Instructional leaders, therefore, allocate most of their scheduled time to activities that have a direct impact on student achievement, such as: curriculum coordination, selection of instructional materials, and professional development planning – all of which can involve ICT integration in them if necessary. The role of the instructional leader is not limited to the principal or senior administrator, since it extends also to other key players in the educational institution such as assistant principals, curriculum coordinators, or senior teachers. Despite this model's endorsement by the English National College, however, Bush (2011) explains that it has two main weaknesses, namely: (1) it tends to underestimate and turn attention away from a number of educational purposes and aspects, including student welfare, socialization, and the development of the young into responsible adults and (2) it is limited since it does not explain much about how exactly instructional leadership is to be developed.

With this exploration of a few of the most dominant educational leadership models in the literature, the question about the most suitable leadership style for ICT implementation in education persists. Since, it is obvious, as Bush (2011) explains, that it is rare for any one single model among these models and others like them to capture the reality of leadership within one particular

context or institution. Instead, it is more common to see “aspects of several perspectives present in different proportions within each institution,” with the applicability of each perspective or model varying with the event, situation, or the participants (p. 205). For this reason, we are starting to find new approaches to educational leadership emerging, which although rooted in, and influenced by, traditional leadership theory, are yet different from it in that they do not focus on the characteristics or actions of leaders, but are more functionally oriented, in that they prescribe what in practice leaders should do. Chang (2012) identifies *technological leadership* as being such a type of functionally oriented leadership practice and explains that it “emphasizes that leaders should develop, guide, manage, and apply technology to different organizational operations so as to improve operational performance” and, thus, be effective in their role (Chang 2012, p. 328). To more easily understand what effectiveness in technology leadership precisely entails, however, it helps to first have a clear understanding of what educational leadership effectiveness, in general, is comprised of.

Competencies and Traits of Effective Educational Leaders

Bradley et al. (2017) explain, based on a number of research studies in the literature, that in a university setting, leadership roles require different types of knowledge and skills, such as: knowledge of academic policies and procedures, competency in managing finances and budget, interpersonal and communication skills, and emotional intelligence, and that these skill sets can either be developed through formal training or through experiential learning (e.g., learning on the job or from others) or through a combination of both. In a primary or intermediate or secondary school setting, the required skills and competencies of a leader are not that much different and, at all educational levels, the attributes of an effective educational leader happen to be more or less the same; they include: a solid understanding of the leadership context and its rules and regulations, efficiency in managing risks, provision of suitable and timely feedback, passion for education,

personal moral values, interest in and care for others, emotional intelligence, self-control, and resilience (Bradley et al. 2017). In a more structured sense, Murphy and Seashore (2018) identify nine principles of positive school/educational leadership, through which the characteristics of an effective leader emerge, summarized as follows:

- **Asset-Based:** Consistently concentrates on the assets brought to the institution by all stakeholders
- **Value-Centered:** Emphasizes and expresses in a clear and regular manner enduring values that form the basis of an institution dedicated to human development
- **Virtue-Based:** Consistently acts as an ethical and virtuous role model for others
- **Transcendent:** Sets and pursues a morally compelling vision that moves others to work for the common good
- **Relationally Grounded:** Focuses on developing positive relationships with all stakeholders
- **Means-Focused:** Understands the significant contribution of daily tasks of leadership to bringing about positive change
- **Growth-Based:** Encourages and supports personal and professional development of all school members
- **Authentic:** Demonstrates self-awareness and self-control, transparency, and individual consideration for others
- **Service-Grounded:** Displays a willingness to serve in order to nurture the humanity of all those impacted by the services of the organization

Technology Leadership in Education

Definition of Educational Technology Leadership

There are different definitions of technology leadership in education in the literature; nonetheless, they all share the emphasis stressed by Flanagan and Jacobsen (2003) that such leadership “is much more than resource acquisition and management”; for, it happens to have multiple dimensions, given the complex nature of educational institutions as learning organizations (pp. 124–125). An

example of a definition in the literature portrays technology leadership as representing all activities related to technology in an institution, including organizational decisions, policies, and procedures, as well as implementation (Anderson and Dexter 2005; Dexter 2011; Fletcher 2009 as cited in Sincar 2013, p. 1273). Another definition describes it as an integrated process involving the motivation of all school staff to learn, utilize, and integrate technology into the environments they are working in (Yorulmaz and Can 2016). While, in contrast, Chang (2012) defines it as an important turn away from exclusive school administration to a more current and multifaceted role of curricular and technological headship, which serves as an important strategy for improving academic quality and student outcomes. On the same lines, Abdul Razzak (2013) describes this approach to leadership as a leadership of the current digital milieu, which is capable of impacting all aspects of school capacity and of turning around schools into schools of the future, where preparation for the twenty-first century skills-like utilization of ICT in daily life and work – and beyond – takes place. Finally, Brown (2014) explains technology leadership by stating that, at its core, “it is about teachers, administrators, and technology leaders at all levels who embrace and realize the potential of educational technology to enhance student learning experiences, regardless of whether the learning occurs in a traditional or in a distance learning classroom” (p. 1).

Roles and Responsibilities of Technology Leaders in Education

Educational institutions as learning organizations are quite complex and their complexity amplified even more with the arrival of digital technologies, which placed additional demands on teachers and administrators alike. This is because the advancement of technology infused new energy into educational reforms in many countries around the world (Chang 2012), which became translated into official governmental mandates to organize schools and HEIs through ICT, and to integrate ICT in almost all their activities. Teachers and administrators, therefore, now find themselves

having to do more in order to cater to the needs of the new generation of learners, who are technology literate and digitally engaged and who, therefore, require different pedagogical conditions and approaches than the generations before them. This calls for the creation of a special type of culture within educational institutions that focuses on ICT integration and encourages exploration of new teaching, learning, and management techniques. Accordingly, leaders in such institutions are challenged to steer the ship toward the creation of such a culture, and a significant number of research findings point to the need for a technological leadership approach, which happens to have a multiplicity of dimensions. Before uncovering what these dimensions are, however, it helps to pave the way for them through reviewing some of what is found in the literature on the roles and responsibilities of technological leaders in education.

To begin with, Hall (2008) (as cited in Puckett 2014) explains that, “to be an effective leader in Educational Technology, one must identify what type of leader (s)he is. This type of identification requires sincere reflection” (p. 1). In addition, the technological leader should be decisive and directive since his/her main responsibility is to strike a balance between being a leader in the educational realm, on the one hand, and being able to motivate and appropriately manage a group of staff members in the technological realm, on the other (Puckett 2014). To be able to motivate others about technology and to succeed at guiding and managing their ICT-related attempts, leaders must be “actively supportive and learn the knowledge of ICT as well” (Betz 2000, as cited in Seyal 2015, p. 32), or else, they would not be able to provide their staff with adequate professional development opportunities needed for effective ICT integration in teaching and learning. They also would not be able to set and successfully implement educational technology plans (Seyal 2015), which, according to Picciano (2011), are required at all levels in an educational institution, in order to nurture the necessary ingredients for sustainable and effective ICT integration and development – ingredients like commitment, collaboration, and continuity. Such educational

technology plans usually focus among other things on: developing ICT-related policies and procedures; budgeting for ICT; securing a good technological infrastructure in the institution in terms of facilities, wired spaces, and connections; providing the needed resources for ICT integration (e.g., hardware, software, peripheral devices, multimedia, Wi-Fi, SMART boards, learning and information management systems, e-subscriptions, etc.); identifying potential ICT-related security issues and risks and setting strategies for managing them; recruiting sufficient and skilled technical support staff; providing professional development opportunities, which include both ICT literacy and ICT pedagogy, primarily for the teaching staff but also for the leaders in the institution (Abdul Razzak 2013). Last but not least, these plans are also needed for building a culture of acceptance of, if not enthusiasm toward, change and the adoption of new teaching and learning methods based on the utilization of ICT, where this culture is embedded in a positive environment that promotes, supports, and rewards creativity, inquiry, and innovation, especially when it is ICT-related (Flanagan and Jacobsen 2003; Chang 2012; Picciano 2011; Puckett 2014).

With respect to the teaching and learning methods that work best with ICT integration, research findings internationally have placed considerable emphasis on those associated with the constructivist model or approach, which represents the new educational paradigm of our time (Picciano 2011; Brown 2014; Flanagan and Jacobsen 2003). Brown (2014), for example, emphasizes that “for a leader to be successful in technology, he/she must be aligned with specific current best practices associated with desirable outcomes. Educational technology leaders can align themselves with Constructivist Methodology as part of best practices approach to improve teacher efficacy” (p. 1). By improving teachers’ efficacy in constructivist strategies, the expected result is that teachers will be more capable of continuously engaging students in authentic learning activities and opportunities, which are supported by the use of appropriate technology, and require and stimulate communication, inquiry, decision-making, and problem-solving

on the part of the learners (Flanagan and Jacobsen 2003). This, consequently, will result in enhanced student outcomes, since through it students “go beyond memorizing and reproducing theoretical models in the classroom” (Brown 2014, p. 2) to being engaged in posing their own questions, researching, and constructing their distinct knowledge and meanings of the world around them (Flanagan and Jacobsen 2003). Through such constructivist and ICT-enriched experiences and student engagement, learning can even extend “beyond the classroom walls through online collaboration, research and communication, sometimes with experts in the field” (Flanagan and Jacobsen 2003, p. 129). Since a key element of successful and effective ICT integration is student engagement, the technology leader’s responsibility therefore is to ensure a constructivist approach to teaching and learning within the educational institution, by which instructors’ roles change from being mainly the disseminators of knowledge to wise mentors and facilitators, who support students in their journey toward construction of meaning (Flanagan and Jacobsen 2003, p. 129).

In addition to playing a major role in setting the direction of teaching and learning within educational institutions, technology leaders must also be kept informed and remain up-to-date with the latest discoveries in both technology and learning theory, in order to thoroughly understand what skills students need for succeeding in the highly technical and competitive workforce they will be exposed to after graduation, and how to develop such skills (e.g., self-regulation, social competence, and adaptability) (Brown 2014). To be kept informed and remain up-to-date in such a manner, technology leaders themselves need to receive relevant training and professional development, whether in the form of internal workshops or mentoring sessions within their educational institutions, or external courses and certification within their communities or internationally, or even online courses, or better yet according to some researchers and practitioners, participation in professional learning networks (PLNs) or communities of practice. PLNs, in particular, are considered to be by some scholars crucial for technology leaders; as Brown (2014)

explains, technology leaders tend to usually feel “a sense of professional isolation” which, however, diminishes when one joins a PLN and which gets gradually replaced with “a real sense of being a part of, and being plugged into, a larger community of like-minded professionals” (p. 3). By the same token, Puckett (2014) sees PLNs and knowledge-sharing among best practices to be adopted by technology leaders and emphasizes that such leaders should not only join PLNs but, instead, should also promote such networks and other relatively new forms of professional development, such as collaborative action research, within their institutions, so as to create opportunities for staff to learn from one another and professionally grow. For, through such networks and collaborative research efforts, staff have the chance to discuss and reflect on what works and does not work in their classrooms and in those of others, and thus make use of these activities as platforms, not only for showcasing their success stories with ICT integration but also for inspiring others to continue with what they are doing and/or to incorporate new things into their classroom practices. Accordingly, ensuring the establishment and activation of PLNs and collaborative action research is an important responsibility among the myriad responsibilities of an effective leader in educational technology, which cannot and should not be neglected, especially when empirical research (e.g., Flanagan and Jacobsen 2003; Puckett 2014) has indicated that “educational leaders, who allow their staff to discuss and observe what works and does not work with technology implementation in other classrooms, will have better results with teachers’ attempts to integrate technology in the classroom” (Puckett 2014, p. 2). Positive results tend to also intensify in institutions where technology leaders themselves fulfill their responsibility of acting as inspiring role models of ICT integration and as providers of appropriate rewards and incentives for those “who become substantially involved with developing other staff and implementing technology in their school” (Picciano 2011, p. 222). For as Puckett (2014) maintains, “when staff members feel accomplished and appreciated, they are more inspired to continue with the work

they are doing and eventually incorporate new things into their regime” (p. 2).

In summary, therefore, educational leaders as leaders of technology have a multiplicity of responsibilities on their shoulders, with many hats to wear and many roles to undertake. From the review of the research literature provided above (and from other omitted studies), it is safe to conclude that the roles of the technology leader happen to be, as depicted by Yorulmaz and Can (2016), related to “technology-orientation, instructional program, infrastructure, facilitation, planning, communication, personal development, supervision, ethics, safety, technology budget, public relations, change and technology policy” (p. 48). The demands on the technology leader are, therefore, huge and call for appropriate and solid training, which can result in the acquisition of a crucial set of higher-order competencies and accompanying behaviors, in the development of some essential personal attitudes and mindsets. These competencies, behaviors, attitudes, and mindsets to be possessed by leaders of technology in education have been determined by several organizations within the context of educational technology standards and have been categorized in a number of dimensions. The section below provides an overview of a number of dimensions of technology leadership derived from a multiplicity of sources, mainly The International Society for Technology in Education (ISTE) standards of technology leadership, known as the *National Educational Technology Standards for Administrators* (NETS*A), and empirical literature on effective educational leaders in schools and HEIs in general, and on effective technology leaders specifically.

Dimensions of Educational Technology Leadership

Table 1 demonstrates, on the basis of NETS*A and the research findings of a number of studies in the empirical literature, the dimensions or areas in which technology leaders must be trained, in order to effectively fulfill their role in “supporting digital age learning, implementing technology, and transforming the educational landscape” (ISTE 2009 as cited in Sincar 2013, p. 1274).

Leadership on Information Technology in Education, Table 1 Dimensions of educational technology leadership or areas in which technology leaders must be trained

NETS*A standard theme	Standard description	Training needed <i>The technology leader must be trained to:</i>	Empirical research used
Visionary leadership	Educational directors inspire and lead people to develop and implement a shared vision to realize comprehensive technological integration across the organization and support perfectionism and transformation	Explore the direction and trends of technology development and the potential uses of technology in the classroom Develop a well-defined vision of how school improvement and effectiveness will be impacted by technology Communicate and share the vision with all stakeholders and continuously reinforce values related to the vision Strategically plan for technology integration and develop supporting policies and procedures for it	Yieng and Binti Daud (2017) Bennet (1996) Flanagan and Jacobsen (2003) Yorulmaz and Can (2016) Chang (2012)
Digital age learning culture	Educational directors create, support, and maintain a digital age learning culture offering suitable and attractive education for all students	Properly communicate and positively interact with others Provide support to encourage adoption of new teaching and learning strategies incorporating ICT Serve as a role model for promoting use of ICT in learning Meet the individual technological and pedagogical needs of all those involved in the learning process Participate in local, regional, and international learning networks and communities focused on innovation in ICT integration and encourage others to do the same	Yieng and Binti Daud (2017) Yorulmaz and Can (2016) Chang (2012)
Perfectionism in professional practice	Educational directors try to strengthen professional development and innovation activities to enhance student learning by means of the integration of contemporary technologies and digital resources	Plan and secure resources (e.g., finances, equipment, human resources, and time) for staff professional development Support staff in their individual professional development and growth plans Build opportunities for collaboration and knowledge sharing between and among colleagues	Yieng and Binti Daud (2017) Flanagan and Jacobsen (2003) Yorulmaz and Can (2016) Chang (2012)
Systematic development	Educational directors offer the leadership and management of digital age for the continuous development by making effective use of information and communications resources	Evaluate individual staff members' performance and growth in relation to set technological targets and utilize evaluation results to inform decision-making, planning, and improvement Research student achievement and grades and utilize the analyzed results for improving teacher performance and student learning Collect and analyze data on staff's ICT implementation, to identify technology savvy employees and develop plans on how to invest in them, retain them, and recruit others with similar profiles	Yieng and Binti Daud (2017) Yorulmaz and Can (2016) Chang (2012)

(continued)

Leadership on Information Technology in Education, Table 1 (continued)

NETS*A standard theme	Standard description	Training needed <i>The technology leader must be trained to:</i>	Empirical research used
Digital citizenship	Educational directors design a conception of related social, ethical, and legal responsibilities conducive to the development of digital culture	Promote, model, and develop policies and procedures for safe, ethical, and legal use of digital information technology Provide professional support to ensure equal access to technological resources and appropriate technology-use environments and spaces for the whole institution Establish institutional-wide understanding of an involvement in global issues through modern digital communication tools	Yieng and Binti Daud (2017) Flanagan and Jacobsen (2003) Yorulmaz and Can (2016)

Table 1 is divided into four columns, where the first column designates the theme of each standard of NETS*A, followed by the second column which includes a description of the standard, and then by the third column which indicates the training needs to be met. As for the fourth column, it lists the research studies highlighting the training needs derived from the NETS*A for technology leadership, which are standards that were originally intended to help educational leaders in the following tasks, as highlighted by Sincar (2013, p. 1274):

1. Understand their roles as technology leaders
2. Provide technological needs of all stakeholders
3. Fully accomplish technology integration in the educational process

Becoming a technology leader in an educational institution requires, therefore, a great deal of training in diverse areas. It also requires the fulfillment of many responsibilities. No matter how well-trained a technology leader is, however, and no matter how efficient they are in effectively fulfilling all that is expected of them, their position is not free of complications. On the contrary, the nature of ICT integration as a new movement in education, which demands transformation and change, brings along with it many challenges of diverse sorts. These challenges are usually referred to as “barriers” in the literature; they

carry the potential of hindering the success of ICT implementation in education and, consequently, impairing the effectiveness of the technology leader’s practices and attempts.

Barriers to Effective Educational Technology Leadership

Technology leaders experience diverse challenges in their educational practices, and Sincar (2013) groups these challenges under five major themes: *technology training, resistance, resources, equity, and bureaucracy*. A thorough search of the literature also conveys a general conformity in research findings on these themes.

In terms of *training*, the major challenge is the lack of it or the irrelevance or inappropriateness of what is provided. Even principals and senior administrators are in some cases not well-prepared for technology leadership responsibilities they are supposed to undertake and, as a result, find themselves lacking the necessary pedagogical competencies and experience needed to guide others in ICT integration. For this reason, we find in many schools the phenomenon of what Flanagan and Jacobsen (2003) call “informal technology leaders,” who emerge “from classrooms, libraries, and computer labs to take up the difficult task of planning for technology integration, and supporting distributed and often uncoordinated efforts by enthusiastic teachers” (p. 128). In many cases also, we find ICT technicians playing the leadership role in the place of the

untrained principal or senior administrator, especially when the latter lacks sufficient knowledge of how hardware and software selections/choices impact student learning and outcomes (Flanagan and Jacobsen 2003, p. 128). For this reason, training resulting in ICT literacy and ICT pedagogy is emphasized by many scholars as a key factor in the context of technology leadership (Abdul Razzak 2013; Chang 2012; Flanagan and Jacobsen 2003). One problem reported by educational leaders, however, is that their job is highly demanding and that they spend most of their time on solving problems in their schools and, as a result, do not find time for working on their own professional development (Sincar 2013). Nevertheless, finding ways and time for ICT-related professional development is a must for any educational leader who aims at making technological innovation a reality in their institution, no matter how overwhelmed they may be. For, without such professional development of leaders, it would not be possible for them to support the development of teachers and others involved in the core functions of education within their institution, whom themselves are in need of “responsive and flexible professional development opportunities that focus on technology integration and design, rather than computer applications alone” (Flanagan and Jacobsen 2003, p. 127). Such professional development in ICT integration and pedagogical design is something that teachers are in dire need of, since considerable research findings indicate that many teachers lack the basic competencies and knowledge for designing technology-based lessons and, many times, they try to integrate technology without fully understanding it as a concept or comprehending the context in which it should be utilized (Abdul Razzak 2013; Jenkinson 2009 as cited in Puckett 2014, p. 4). Instructors involved in online teaching or e-learning, in particular, are in need of training which focuses on appropriate design of online activities and lessons and on relevant modes of interaction in an online environment; for, as Abdul Razzak (2016) has found, too often and in very few institutions “are web-based course management software or as they are called, learning management systems

(LMS), like BlackBoard and MOODLE being activated by some faculty for more than posting course announcements, course documents, supporting reading materials, assignments, and grades” (p. 885). There is no substantial evidence, therefore, of online teaching methods being utilized to capitalize on students’ higher-order cognitive skills, such as critical thinking and creativity. Besides, many instructors “are still uncomfortable with designing basic online activities to begin with” and, accordingly, need training in this area first before they receive training on how to design online activities that both engage students actively and enhance their higher-order thinking skills and deep learning (Abdul Razzak 2016, p. 885).

With respect to *resistance*, it usually comes from the side of the teachers; “while educational technology may be exciting to some, to many educators it is highly stressful, as it is uncharted territory” (Puckett 2014, p. 4). Thus, it is natural that teachers do not find it easy to have to make changes to the teaching practices that they have been accustomed to using for years. Teachers who are close to retirement, in particular, are usually the most resistant to using technology in education and they sometimes, unfortunately, adversely influence younger teachers’ motivation and behaviors related to ICT implementation (Sincar 2013). This constitutes a challenge for technology leaders since without strong teachers’ buy-in and commitment to ICT integration, the leaders’ role of creating, supporting, and maintaining a culture of digital age learning gets impeded.

In addition, several issues with *resources* comprise a barrier to effective technology leadership. What is meant by resources here is both material and human resources. With respect to the material resources, the lack of availability of sufficient and adequate technology spaces and physical facilities, as well as the lack of availability of up-to-date technology, pose a challenge to technology leadership in many institutions, especially in communities with low income (Thomas and Kzenek 1991; Richardson and McLeod 2011 as cited in Sincar 2013, p. 1275). Lack of availability and insufficiency of physical resources is not the only

barrier, however. In some cases, the challenge for technology leaders has to do more with planning for resources than their availability, and this is why it is not uncommon to find many schools that actually have the latest technologies and very expensive computer laboratories, but which nevertheless are not making use of them for meaningful and constructive technology-enhanced lessons. The problem here is with resources' planning that happens to focus mainly on the acquisition of hardware and software and on the wiring of facilities without much regard for "substantial organizational and cultural changes that are necessary to support appropriate use of technology to enhance student learning" (Flanagan and Jacobsen 2003, p. 128). Other challenges related to human resources in particular that technology leaders face have to do with the inability to find skilled technology coordinators and the insufficiency of technical personnel to support educational institutions with their troubleshooting issues (Sincar 2013).

Among the barriers to technology leadership also are some *equity issues*. These issues are represented through an unequal distribution of educational-based technologies among schools and HEIs in most countries. This happens because some educational institutions have or receive more funding and resources than others and, many times, the disadvantaged ones are located in low-income communities or areas (Flanagan and Jacobsen 2003; Richardson and Mcleod 2011 as cited in Sincar 2013, p. 1275). These equity issues have the potential to impact the core functions of teaching and learning; when students do not have sufficient and well-prepared and adequate facilities, they tend to fall behind in the use of education-based technologies (Sincar 2013, p. 1282), which can have an adverse impact on their achievement of expected learning outcomes, especially in comparison to other students who study in advantaged institutions. Accordingly, a major challenge for technology leaders is to ensure their educational institutions "are places where inequities are eradicated rather than exacerbated by the integration of technology" (Flanagan and Jacobsen 2003, p. 127). On the

same lines, technology leaders need to ensure that there is something for everyone in terms of educational-based technologies, meaning they need to be sensitive to diversity in terms of gender, economic background, ethnicity, and language, as well as to other systemic barriers that impact students' use of technology (Flanagan and Jacobsen 2003). Teachers' and students' different learning approaches, in particular, need to be taken into consideration and catered to. This is in addition to a student's achievement levels, where in many cases a need may present itself to have to provide special computer-assisted instruction (CAI) for lower-achieving students and students with identified disabilities. Several research studies have indicated that such groups of students tend to make significant gains with the application of CAI as a supplemental activity to teacher-directed instruction and tend to benefit more from it than from other interventions such as additional traditional teaching and/or drill exercises (Hall et al. 2000; Jeffs et al. 2006).

Finally, *bureaucracy* is reported in many research findings as being one main challenge that slows down the practices of technology leaders in education (Nance 2003 as cited in Sincar 2013, p. 1275). Bureaucratic obstacles are also considered as the most difficult to overcome. Usually these types of obstacles lead to delays in, if not total prevention of, the introduction of new technologies into educational institutions; they also raise difficulties in the fulfillment of some educational demands (e.g., training, coaching, mentoring, or curriculum coordination) related to technology. As a result, this can have negative effects on the quality of education, because of missed opportunities that pass by untapped, due to delays or other forms of obstacles resulting from bureaucratic processes. The technology leader's effectiveness, consequently, gets destabilized in the course of events.

Despite the diverse barriers to technology leadership, many of them are surmountable, especially with a proactive approach, and with appropriate training, passion for education, and enthusiasm for innovation. Successfully embodying many leadership roles at the same time is also important.

In particular, as Flanagan and Jacobsen (2003) conclude, the technology leader should be effective simultaneously as a leader: (1) of learning, (2) of student entitlement, (3) of capacity building, (4) of community, and (5) of resource management.

Conclusion

To sum up, educational leaders are key factors in ICT integration in schools and HEIs. As technology leaders, their role is central yet not easy; their effectiveness in this role impacts a multiplicity of core practices in education, primarily: instructors' and students' learning of technologies; instructors' use of technologies in designing and teaching lessons; and students' learning with and through technology. The more successful such leaders are, the greater the positive influence they have on teachers' professional development and actual implementation of technology-infused teaching, which in turn results in improved student achievement and learning outcomes. To have powerful influence of this kind and to be able to sustain it, it is mandatory for technology leaders to demonstrate the following attributes and behaviors:

- Be vision-oriented with respect to the direction of educational technology
- Engage in effective strategic planning (i.e., setting goals) that is based on an assessment of their educational institution's needs in relation to all educational technology requirements (equipment, hardware, software, human resources, infrastructure, etc.)
- Possess the capacity to motivate their staff to become engaged in ICT-related activities
- Develop strong personal buy-in and commitment to educational technology
- Go above and beyond securing access and sustaining effective implementation of educational technology, i.e., they need to be excited and passionate about ICT in education
- Be knowledgeable and stay up-to-date about the latest technologies and educational technology practices
- Be role models of successful ICT integration within their institutions
- Promote an inviting school culture toward innovative educational technology implementations and practices
- Ensure the recruitment of committed educators in terms of their attitude/practice toward educational technology and ensure for them the provision of sufficient and adequate professional development training opportunities related to educational technology implementation
- Encourage collaboration among teachers so that they work together on educational technology projects and share experiences and practices and learn from one another
- Establish partnerships with community members (parents, businesses, software developers, other schools and HEIs, etc.) that could benefit the educational technology initiatives in their institutions
- Value any educational technology initiative/attempt and celebrate educational technology success stories within the school
- Provide appropriate incentives for technology savvy staff implementing educational technology
- Support and encourage the utilization of educational technology as a vehicle for inclusion (i.e., including also students with disabilities)
- Promote the implementation of action research in relation to educational technology implementation, so that teachers and other staff can learn from their own mistakes and experiences and can develop themselves on the job or in the field

Only by demonstrating such attributes and behaviors can technology leaders have a better chance at effectively leading and preparing their institutions not only for this decade but also for decades to come. Only then, also, can they expect to witness good, if not excellent, success stories of ICT integration within the educational communities they lead; as Puckett (2014) puts it, although "a leader must expect excellence; (s)he must also display excellence" (p. 1).

Learning Behaviors in Programming

Francisca A. Adamopoulos
School of BIT&L, RMIT University, Melbourne, VIC, Australia

How students go about their learning has been widely researched from various perspectives. Deep and surface learning is a key perspective

taken by many researchers. Another view has been to look at good and poor learning tendencies. Several models of how students experience the learning of IT and programming have also been developed. Yet another perspective is that of student engagement: behavioral, emotional, and cognitive. This entry presents these various perspectives of learning behaviors.

Deep and Surface Learning

Various authors have sought to explore how students learn from the perspective of surface learning and deep learning. While the majority of these studies (and models developed) are from a general education perspective, a few studies have focused specifically on the information systems, computer science, and accounting contexts.

Biggs contends that the approaches to learning are formed by motives (intention) and strategies (actions). It is the learning approach the student chooses (surface, deep, or achieving) that affects the quality of the learning outcome (Biggs 1989; Biggs and Tang 2007, 2011; Carbone 2007):

- *Surface Approach*

The surface approach is based on an extrinsic motivation such as choosing to do a degree at university as a means to some other end such as obtaining a better job or to achieve a pass as a result of having to take a subject that is irrelevant to the student's program. This approach arises from the intention to get the task out of the way with minimum effort while appearing to meet the task requirements. It involves "cutting corners" to give the impression that the task was properly done; this is to avoid failure. Students focus on the isolated items and treat these independently of each other or to other tasks. They focus on the literal facts missing their meaning (rote learning). There is also a presence of negative feelings such as anxiety, cynicism, and boredom. There may be other factors that encourage a surface approach such as insufficient time, misunderstanding requirements, high anxiety, or a cynical view of the subject or of the teaching context itself.

- *Achievement/Strategic Approach*

The achieving approach is based on a particular type of extrinsic motivation: the need to achieve through high grades using a surface approach. The strategies used consist of organizing time, working space, and syllabus coverage in the most cost-effective way. Their approach is systematic, planning ahead and allocating time to tasks in proportion to their earning potential.

- *Deep Approach*

The deep approach is based on an intrinsic interest in the subject matter that is being learnt. The strategy used aims to maximize understanding so that curiosity is satisfied. Students feel the need to engage in the task appropriately and meaningfully. They feel a need-to-know so they focus on understanding the underlying meanings rather than the literal aspects. They seek to integrate the parts with other tasks and also with the big ideas in the domain.

The student reads widely, discusses with others, and may play with the task in order to hypothesize how it relates to other known or interesting items. Students generally have positive feelings when using a deep approach such as feelings of interest, challenge, and exhilaration. Factors that promote a deep approach include an intrinsic curiosity or determination to do well, an appropriate background knowledge, and a well-structured knowledge base.

A model more specific to information systems was developed by Cope (2000), who sought to investigate the relationship between approaches to learning and levels of understanding of the concept of an Information System (IS) in undergraduate students (Cope 2000, 2002, 2003).

- *Surface Approach*

A surface approach to learning about IS involved a series of isolated and generally unrelated learning and assessment tasks that had to be completed to pass the course. Knowledge was experienced as facts contained in lecture notes and summaries, formulae, and skills on how to use software. The intentions

of acquiring the knowledge were to be able to recall the knowledge or to apply the memorized procedures in assessment situations.

- *Deep Approach*

A deep approach to learning about IS involved seeking meaning of the content from the learning tasks and assignments with the intent of developing a deep personal understanding that went beyond the immediate task. Meaning was sought through relating the content in the learning tasks to other content from the same course or a different course. Understanding was experienced as having an internalized picture of the content that could be used to link with new material or explain to others.

Cope (2003) described that the educationally critical characteristics that lead to the development of a deep understanding are:

- An intention to seek a deep understanding of the concept of an IS
- The process of seeking and relating the meanings associated with a broad range of different perspectives on the concept of an IS, including perspectives in personal experiences beyond the academic setting and in studies outside IS and computing courses
- An awareness of one's own understanding of the concept of an IS and the approaches being used to learn about IS

Learning activities should center on students being aware of and taking charge of their own approaches to developing a deep understanding of the concept of an IS (Cope and Prosser 2005).

While the Biggs model has been widely cited in computing education literature, few studies were found that specifically investigated deep and surface learning approaches in the programming context. One major study conducted over multiple universities, in multiple countries, of introductory programming students, found that a deep approach to learning was positively correlated with marks in programming, while a surface approach had a negative correlation to marks (de Raadt et al. 2005; Simon et al. 2006).

Learning Behaviors in Programming, Table 1 Poor learning tendencies (Baird and Mitchell 1991; Carbone 2007)

Learning tendencies	Characteristics
Superficial attention	This involves skimming over a communication, with no attempt to actively process the information in order to generate personal meaning
Impulsive attention	Some parts of a communication that appear interesting are attended to, but others that may be major points are overlooked
Staying stuck	Lack of any strategy to cope with getting stuck except to call for help. No attempt to return to the instructions, reflect on the strategy selected, analyze what has been done so far, or consider alternative approaches
Premature closure	Ceasing work on a task in the genuine belief that it is finished when in fact some things may not have been done
Inappropriate application	Blind application of a memorized procedure in a situation where it is not applicable
Non-retrieval	This occurs when no attempt is made to retrieve one's own existing views and understandings which are relevant to the knowledge being presented. The learner is unsure of conflicts between the school knowledge and their personal views
Lack of internal reflective thinking	The learner is not thinking reflectively about the content as presented "internally" (i.e., within the boundaries of the subject). Each lesson, activity, or even instruction is seen as isolated from the others
Lack of external reflective thinking	The learner makes no attempt to link the content of one subject with the content outside the boundaries of the subject (i.e., world or other subjects)
Ineffective eradication	Persistent reappearance of apparently changed misconceptions or alternative explanations

Another study investigated deep, surface, and strategic learning approaches in programming students. They found that a strategic approach had a strong positive relationship with performance, a surface approach had a strong negative relationship, but a deep approach only had a weak positive influence. They conclude that the students who take a strategic approach are most likely to be successful (Hughes and Peiris 2006).

Learning Tendencies

An alternative view to learning approaches is the concept of learning tendencies (Baird and Mitchell 1991; Baird and White 1982). Baird and Mitchell (1991) describe poor learning tendencies as "descriptions of poor thinking habits – of deficiencies in the way learners tackle tasks or process information." Baird and Mitchell found that poor learning tendencies were frequently responsible for poor learning performance, but often unintended, and that students were unaware of them, even by those with a good level of commitment.

Carbone (2007) used these poor learning tendencies as a "base for determining the type of

thinking undergraduate IT students did not do as they engaged in their programming tasks." A summary of these poor and good learning tendencies is shown in Tables 1 and 2.

Carbone (2007) also found that programming students can suffer from poor time management. Failed attempts to complete a working system within the timeframe allowed led students to prioritize the activities to complete and choose those that would achieve the best grades possible. They also abandoned their attempts to understand the problem and opted to copy slabs of code from the textbook without fully understanding it (Carbone 2007; Carbone et al. 2009).

Ways Students Experience Learning IT and Programming

Other studies in the way students approach their learning in the fields of computer science (CS) and IT have demonstrated that students experience their learning in different ways.

Berglund et al.'s study presents seven categories which describe the way students act to learn computer science, where the more advanced categories with a higher number describe a more

Learning Behaviors in Programming, Table 2 Good learning tendencies (Baird and Mitchell 1991; Carbone 2007)

Summary	Possible actions
Seeks assistance	Informs teacher when they don't understand
	Asks teacher why they went wrong
	Informs teacher what they don't understand
Checks personal progress	Checks work against instructions, correcting errors, and omissions
	Refers to earlier work when stuck before asking the teacher
	Checks personal comprehension of instruction and material
Plans and anticipates	Anticipates and predicts possible outcomes
	Plans a strategy before starting
	Explains purpose and results
Reflects on work	Checks teacher's work for errors and offers corrections
	Seeks links between adjacent activities and ideas
	Seeks links between different topics
	Independently seeks further information
Links to beliefs and experiences	Seeks links between different subjects
	Asks inquisitive but general questions
	Offers personal examples which are generally relevant
	Seeks specific links between school work and personal life
	Searches for weakness in their own understandings
Assumes a position	Checks the consistency of their explanations across different situations
	Suggests new activities and alternative procedures
	Expresses disagreement
	Offers ideas, new insights, and alternative explanations
	Justifies opinion
	Reacts and refers to comments by other students
	Challenges the text or an answer the teacher sanctions as correct

L

sophisticated way of acting to learn. Categories 1–6 describe learning CS through (Berglund and Wiggberg 2008):

1. *Learning to use application programs*, focusing on learning the tools that are used and neglecting the other aspects in the field taught by the computer science community
2. *Learning CS through learning about isolated concepts*, focusing on learning concepts/topics of CS rather than what can be done with what is learnt
3. *Learning CS through consolidating what is already known*, where deeper insights about CS concepts are sought but concepts are still seen in isolation
4. *Learning CS through analyzing systems*, focusing on learning the whole in order to explore the different concepts which make up the parts
5. *Learning CS through integrating systems*, focusing on learning by splitting the units in the software system into pieces and analyzing the parts and then putting the components together, as a way to learn about and to create a system
6. *Learning CS through giving meaning to concepts*, focusing on seeking personal insights and personal meanings to the CS concepts
7. *Learning CS through developing as a professional*

Peters et al. (2014) phenomenographic study focused on understanding the distinct ways students participate in CS and IT using the idea of participation from Wenger's social theory of learning. Participation in CS/IT was experienced as:

- *Using*: to make use of what exists for various purposes.

- *Inquiry*: activities that aim at understanding, learning, and informing.
- *Creating things*: to produce things that were not there before. The aspects that are related with this category are the outcome and the process of doing and doing with others.
- *Systematic problem-solving*: this includes using methods, ways of thinking, and systematically working with others to create things.
- *Creating for others*: this includes taking into account the user's perspective in the process of creating and problem-solving.
- *Continuous development*: as a continuous process of improvement.
- *Creating knowledge*: to develop new solutions, (to do research).

Introductory programming courses often have highly bimodal grades – many students failing or obtaining high grades. Robins (2010) proposes this may be due to what he calls “learning edge momentum” (LEM). Concepts in the programming domain are tightly integrated, where almost every concept depends on many others. Successful learning of a concept makes it easier to learn further related concepts. In contrast, unsuccessful learning of a concept makes it harder to learn other closely linked concepts. This then creates a momentum towards a successful or unsuccessful outcome (Robins 2010).

Another factor that explains the LEM effect is that “we learn at the edges of what we already know.” “Understanding (on a short time scale) and learning (over a longer period) depends on fitting new material into the context of existing knowledge” (Robins 2010).

Bruce et al. (2004) investigated how first-year university students experience the act of learning programming. The experiences are described as five different categories that describe how learning to program is experienced:

- *Following*: describes the experience as following the structure of the unit to get through it (struggling to keep up and focusing on the tasks that gain marks).
- *Coding*: describes the experience as learning to code (focusing on learning the syntax of the

programming language expecting intensive direction from experts and teachers).

- *Understanding and integrating*: describes the experience as seeking understanding of the big picture, experimenting with code, and becoming more proficient with coding in order to understand the concepts and apply them in different ways.
- *Problem-solving*: describes the experience as learning to do what it takes to solve problems. The primary focus is solving the problem, and coding is seen as part of the learning process.
- *Participating or enculturation*: describes the experience as learning what it takes to be part of the programming community and culture. This involves understanding what the programmer thinks and does in order to communicate with other programmers in that community.

Engagement

Engagement has been described as a multi-dimensional construct that integrates and blends the concepts of behavior, emotion, and cognition (Fredricks et al. 2004). Engagement has been associated with positive academic outcomes, such as achievement and persistence in school. It has also been found to be higher in classrooms with “supportive teachers and peers, challenging and authentic tasks, opportunities for choice, and sufficient structure” (Boekaerts 2016; Fredricks et al. 2004).

Three different types of student engagement have been described (Carbone 2007; Fredricks et al. 2004):

- *Behavioral Engagement*
 - Positive conduct, such as following rules and adhering to classroom norms, as well as absence of disruptive behaviors such as skipping school and getting into trouble
 - Involvement in academic tasks which includes behavior such as effort, persistence, concentration, attention, asking questions, and contributing to class discussion
 - Participation in school-related activities such as athletics or school governance

Behavioral engagement contributes towards positive academic outcomes.

- *Emotional Engagement*

Students' affective reactions in the classroom towards teachers, classmates, and school – both positive and negative. These include interest, boredom, happiness, sadness, and anxiety and are considered to influence the willingness to do work. These emotions overlap with many of those reported in the motivational literature.

- *Cognitive Engagement*

“Effort directed towards learning, understanding, mastering the knowledge, skills or crafts that the academic work is intended to promote” (Fredricks et al. 2004). Cognitively engaged students show flexibility in problem-solving and the ability to cope with failures. They use deep-level strategies, exerting greater efforts to achieve a more thorough understanding. They want to go beyond the requirements and prefer a challenge.

The concept of engagement has been widely studied in recent years (Boekaerts 2016; Eccles 2016). Azevedo (2015) found more than 32,000 articles in PsycINFO about engagement published in the last 14 years. Researchers have broadened the original three-dimensional framework of engagement to include agentic, self-regulatory, and social-behavioral components (Boekaerts 2016). Influences on engagement have also been explored, such as teaching staff, peers, structure, and task characteristics (Fredricks 2011).

In a recent study of engagement in first year ICT students, Sheard et al. (2010) used the three types of engagement as a framework to analyze the data. Low behavioral engagement was identified as poor class attendance and lack of weekly study time, with students spending half of the recommended time. They also displayed a lack of organizational ability where they put low effort at the start, which must be increased when assignments are due. Irregular study patterns may be also influenced by outside work commitments (Sheard et al. 2010).

Low cognitive engagement manifested itself as a low involvement and investment in study time.

While teachers expected students to work more independently and to read the lecture notes prior the lecture, few did. Students, on the other hand, expected more guidance, concrete examples to learn from, and specific topics to learn for the exam (Sheard et al. 2010).

Affective engagement was related to the level of interest students had in the course content. Students were keen to learn the applications but not that interested in fundamental concepts. Differing levels of ability were found to influence engagement. Highly engaged students have an interest in the area and have already learnt some ICT on their own or from high school. In contrast, lower engaged students failed to attend classes and avoided consulting teaching staff (Sheard et al. 2010).

Learning Outside the Classroom

With the wide adoption of learning management systems and course materials being accessible online, students now have much greater flexibility in choosing the mode, place, and time of their learning (Sheard et al. 2013). Relatively few studies, however, have investigated programming student study habits outside the classroom.

In a survey of programming student study habits, Chinn et al. (2010) found that “students engaged in a wide range of study behaviours in terms of time spent and use of resources.” Students spent as much time accessing the Internet as reading the textbook. While the majority of their students said they preferred to study alone, they also reported that 95% of students spent at least some time each week talking to friends and classmates about the unit. Their female students tended to work more with others than the male students, and they reported this as being a negative factor on their results (Chinn et al. 2010; Sheard et al. 2013).

A follow-up study by Sheard et al. (2013) sought a more holistic understanding of the study habits of programming students. Students reported studying in various locations, such as at home, on campus, or on the train. Many students reported spending minimal study time after

tutorials and then spending intense periods of study time during assignment/exam time.

Students reported using various study techniques outside the classroom. Most reported reading lecture notes, summary notes, and the textbook (as a reference source or for code examples). Many also heavily relied on online materials. Most students also reported attempting lab and tutorial exercises outside of class time, but only some tried running code examples. Students found that working with others was helpful; however, most preferred to work on their own (Sheard et al. 2013). In a recent study of programming study habits, Willman et al. (2015) found that “students who receive the highest grade start and finish their work early, do not work on weekends, and do not work at night.”

Summary

This entry presented various perspectives of student learning behaviors: deep and surface learning, good and poor learning tendencies, how students experience the learning of IT and programming, and student engagement. Much of this research, however, has been focused on how students learn inside the classroom. More understanding is needed on how students are learning programming outside of the classroom.

Synonyms

[Course management systems](#); [E-learning](#); [Learning content management systems](#); [Online learning](#)

Introduction

There can be no doubt that technology has transformed the way education is delivered to people across the globe. We now live in an interconnected world where the traditional concept of formal learning, taking place in a single physical location, is becoming increasingly less relevant. Modern learners are becoming dissatisfied with the stand-and-deliver approach to education that dictates attendance times, learning venues, and modes of participation. The emergence of sophisticated communication technologies and mobile devices has enabled a

new generation of information consumers to satisfy their demands for knowledge without the need to meet in a physical location. Software vendors, open-source developers, and educational institutions, cognizant of this development, have embraced systems that can facilitate the management of courses and engagement with students remotely. The technologies that facilitate the provision of courses over long distances are broadly termed “learning management systems” or “LMSs.” Learning management systems can be defined as web-based software platforms that provide an interactive online learning environment and automate the administration, organization, delivery, and reporting of educational content and learner outcomes.

Acronym Confusion in the Online Learning Space

There are many terms associated with online learning and the technologies that have evolved to support it. One persistent area of confusion is in the definition of the acronyms: *CMS* and *LMS*. The term *CMS* is often associated with two distinctly different software applications: “content management systems” and “course management systems.” Content management systems are essentially software applications designed for the creation and management of digital content in a collaborative environment. Course management systems on the other hand, according to Watson and Watson (2007, 29), are:

used primarily for online or blended learning, supporting the placement of course materials online, associating students with courses, tracking student performance, storing student submissions and mediating communication between the students as well as their instructor.

To further complicate matters, some vendors and academics prefer to use the acronym *LCMS* which stands for “learning content management system” when referring to content management systems. The difference between a *LCMS* and a *LMS* is that the latter is broader in scope and includes the ability to track learner progress through an online course. It is a gray area where

CMSs end and LMSs begin and many vendors, users, and institutions regard the terms CMS and LMS as synonyms. In this entry, the term LMS will be the only acronym used to refer to online learning platforms.

The Inclusion of LMSs in Distance Education

The history of educational technology is a reminder that it's not the machine that matters — it's finding the tool that best serves your educational objective.
Thornburg (2014, 27)

The history of learning management systems has its roots in distance education. Countries such as Australia, with a geographically dispersed population, adopted measures early in their history to enable access to education for students who could not attend formal places of learning. One of the most prominent manifestations of distance education in Australia was the School of the Air (a correspondence school) which opened to the airwaves in 1951 and is still in operation today in some remote communities. The vocational education and training (VET) and university sectors in Australia also have a rich history of distance education where, prior to the advent of the Internet, communication and the dissemination of learning materials was largely conducted via regular mail services. The availability of dial-up Internet services to most Australians by mid-1995 meant that distance education needed a radical overhaul and *snail mail* was no longer a viable option to sustain distance education services.

Perhaps it was Sidney Pressey's creation in the early 1920s of a "learning machine," a device that could administer questions through a window prompting the user to select a response out of four choices, that spurred the development of the first online LMSs. Or maybe it was the work of a Canadian company, SoftArc in 1990 who built the first stand-alone learning system deployed on Macintosh personal computers, that encouraged software developers to dream of an online learning space. Whatever the inspiration, the arrival of the Internet was set to revolutionize the way

people communicated and engaged with each other and education providers realized that they would have to adapt to this brave new online world. The earliest manifestations of electronic LMSs were little more than a platform for the dissemination of learning materials online. These systems could broadly be categorized as belonging to one of two camps: proprietary and open source. One of the earliest proprietary systems was WebCT, developed at the University of British Columbia in 1995. The creation of WebCT as an online learning platform was inspired by research suggesting that academic performance could be enhanced by the provision of web-based resources. At the height of its use, WebCT was the most widely used LMS globally with over 10 million users in 80 countries. WebCT was later acquired by Blackboard Corporation who phased out the WebCT name in favor of the Blackboard brand.

Open-source systems by contrast, were developed collaboratively by software specialists with a view to making the source code readily available to organizations and individuals free of charge. They were initially popular with universities and colleges who could readily download the source code, adapt it to their own circumstances, and build their own tailored LMS solutions. A prominent example of an open-source system in operation globally today is Moodle. Moodle was developed by Martin Dougiamas with the first version released in August 2002. The acronym Moodle stands for "Modular Object Oriented Dynamic Learning Environment." The system was developed based on a constructivist philosophy emphasizing the role of learners as creators of content and not merely spectators. Moodle is arguably the most popular open-source LMS in use today with almost 100,000 registered sites in 229 countries.

What Are the Features of LMSs That Make Them Great?

A robust, high-quality LMS is a vital tool to the success of any online course and can

Learning Management Systems, An Overview, Fig. 1 LMS feature categories

make or break an institution's reputation in the highly competitive education market. LMSs not only need to provide content to learners, but they must also facilitate timely and accurate communication between learners, course facilitators, and other institutional stakeholders. Yildirim et al. (2004, 125) emphasize that in addition:

an LMS should be dynamic; that is, it should be active, flexible, customizable and adaptable.

Whether a LMS is proprietary or open source, it will need to be capable of executing a variety of functions that work together to provide a seamless experience for the user. These functions include the capability to disseminate knowledge, assessment of learner competency, the recording

of learner attainment, support for online social communities, communication tools, and system security. Figure 1 illustrates the categories of features that are expected to be present in most high-quality LMSs.

Course Management

Course management features encompass a LMS's capacity to deliver timely relevant course material to enrolled learners. It would include such features as content management and control, class scheduling, and content-audit capabilities. The capacity for users to contribute to content creation in their own personal space could also come under this domain.

Assessment

Assessment is a critical function of LMSs. A LMS must be able to support the collection and storage of assessable tasks, along with the assignment of grades and feedback for each learner. Assessable tasks can include assignments, tests, projects, and portfolio evidence provided by the learner. For institutions in the VET space, the capability to automatically generate compliance reports is particularly valuable as it facilitates compliance with quality standards. LMSs should also be capable for providing learners with real-time information on their progress in a course along with relevant feedback generated by the instructor.

Tracking Progress

Attrition of learners is an issue that concerns many institutions. In an online environment, the experience has been that learners are at a greater risk of withdrawing from programs because of the lack of face-to-face contact. The ability to track user engagement in a course is therefore considered an important feature. User tracking analytics can include log-on frequency, time spent in different sections of a course, communication interactions, and the number of resources downloaded. With appropriate reporting functions, course facilitators are able to detect possible student performance deficits and intervene before course withdrawal or termination becomes likely.

Gradebook

Gradebook functions include all LMS capabilities that facilitate the dissemination of assessment information to learners. Such functions include individual scores of assessments, instructor feedback, and student attendance. The ability to generate aggregate reporting information such as class grades, item score analysis, and at-risk student information is included in this category.

Communication Tools

Communication tools within LMSs can be broadly classified as synchronous or asynchronous. Asynchronous tools support one-way communications such as e-mail, discussion boards, or Wikis. They are often preferred by course facilitators because they can be initiated in an ad hoc manner. Synchronous tools, on the other hand, are two-way communication tools supporting real-time information interchange. Examples include instructor-led videoconferences and interactive message boards. This latter class of communication tools is often seen as important to replicating traditional classroom-based communications, thereby fostering a sense of community among online learners.

Social Connectivity

One of the great criticisms of LMSs is the lack of inherent community in online learning. Features that try to replicate a social environment online include discussion forums, live chats, and videoconference tools as discussed in the previous section. Some LMSs even have features that monitor learner interactions with communication tools and are considered invaluable for courses that mandate class participation as an assessable component of a course.

Security and Privacy

Security and privacy are of paramount importance to the success of an online course. Important security features in LMSs include user authentication, access verification, password integrity controls, and intruder detection. Privacy controls are also important to ensure that sensitive information is made available to the intended recipient only.

Ubiquitous Access

People are increasingly dependent on their mobile phones to connect to the Internet. It therefore stands to reason that online course participants need to interact with LMS course environments using their mobile devices. Most LMS providers design course content as responsive HTML pages and are therefore accessible by most smartphones and other mobile computing devices, thus providing ubiquity.

Proprietary or Open-Source Systems: Which Way to Go?

One of the major considerations that an organization has in choosing a LMS is whether to opt for a proprietary or an open-source system. There are pluses and minuses to both approaches, and the choice will largely depend on the resources and expertise the organization maintains in-house and the degree of control they wish to exercise over the administration and future development of the system. Proprietary systems come with the advantage of being developed by a company that specializes in the design and deployment of online learning solutions. The acquisition of a proprietary system usually includes installation and end-user training and does not require any configuration on the part of the client. However, the client institution has limited control over the features provided in the proprietary system and certainly would be unlikely to have access to system source code.

The alternative approach is for an organization to develop its own LMS based on readily available *open-source* code. Moodle, for example, has a popular following and maintains a system of version control and technical specifications for each version.

Krouska et al. (2017, 2) described Moodle as follows:

Moodle is a LMS designed to provide educators, administrators and learners with a single, robust, secure and integrated system to create personalized learning environments. It has a wide range of

standard and innovative features for supporting teaching and learning process. Moreover, it allows for extending system functionality using community sourced plugins.

The source code for Moodle is freely downloadable, and each specific iteration has its own set of installation instructions. Once the source code for a LMS has been downloaded, organizations are free to adapt the code to suit their particular circumstances. Universities and colleges are among the most prolific users of open-source LMSs. This can be attributed to the availability of in-house IT expertise in most universities and colleges and the professional curiosity among IT system decision-makers to develop an understanding of LMS technology through its implementation.

In-House Housing of Data or Cloud Based

Cloud-based LMS solutions are rapidly developing as a viable alternative to on-site installation for client organizations. The choice of adopting a cloud-based LMS largely depends on the degree of confidence an organization has with sensitive data being housed in an environment outside the organization's direct control and whether or not the organization has the infrastructure and expertise to maintain the physical infrastructure necessary to run an on-site LMS. Cloud-based LMSs are usually proprietary systems where the vendor packages the system functionality with the online hosting of the client's data and then charges a fee for the service based on the number of users accessing the LMS site.

The Future of LMSs

As technology evolves and teaching methods become more student-focussed, the LMS of the future will become more than a helpful administrative tool. As improvements in bandwidth, storage, and mobile device computing capacity expand, the capabilities of LMSs will adapt to fill emerging client demands. LMSs should also be supported by an institutional structure

that promotes an equitable learning environment (Chugh et al. 2017). The general trend of LMS systems is to expand learner interactions with course content by including the capability for users to use mobile devices such as smartphones and wearables such as smart watches and smart glasses. Future developments in LMS technology are also likely to include more sophisticated tools to enable genuine synchronous communication, such as videoconferencing apps and peer-to-peer messaging. Below is a list of enhancements to watch out for in future versions of LMSs.

Cloud-Like Functionality

There is already a trend toward cloud-hosted proprietary LMSs as vendors target their offerings to client organizations that do not have the infrastructure or personnel to manage in-house hosting. However, open-source systems such as Moodle are also evolving to accommodate the possibility of their systems existing solely in web hosting environments. For example, a service such as Softaculous can be used to install and configure open-source apps such as Moodle, directly into the client web hosting account.

Adaptive Learning

Adaptive learning technologies permit course designers to tailor learning tasks and materials to individual learner requirements. Examples of the use of these technologies could include the release of learning content based on prior learner assessment, tailored knowledge tests that focus on learning gaps of each individual student, and the incorporation of learner-created content into each learner's portfolio.

Microlearning with LMSs Connected Devices

Microlearning is an approach to education that delivers content to learners in small, very specific pieces. The learners are given control of when and what they will learn. By creating bite-sized training modules within LMS systems accessible to learners on demand, it will be possible for clients to create their own curriculum tailored to their specific requirements. According to Tauber and Wang-Audia (2014, 10):

1% of a typical workweek is all employees typically to focus on training and development.

The microlearning approach to training delivery is therefore likely to prove popular for workers operating under tight time constraints.

Analytical Tools

Reporting functions which have a descriptive purpose such as enrolment reports, assignment submissions, and user access frequency are already standard features of many LMSs. The challenge for future systems is to tap into the rich and diverse data collected by LMSs and use this information to predict problems and opportunities that may arise. For example, most institutions are concerned about attrition and would appreciate being alerted to circumstances that may lead to a student's failure or voluntary withdrawal.

Social Capabilities

The attraction to formal learning for most students in classroom-based environments is not only the knowledge and skills to be acquired but also the social dimension of study that participation in higher learning provides. LMSs have often been criticized for not adequately accommodating this innate learner need. The inclusion of more synchronous communication tools such as live videoconferencing and real-time social media apps is likely to strengthen the appeal of online learning as a social activity. LMS vendors are already tapping into existing social media apps such as Facebook, Twitter, and WhatsApp along with videoconferencing tools such as Skype to provide a social framework for online learners.

Gamification

Learning games, if structured correctly, can provide a fun and stimulating way to engage learners by rewarding their progress. Future gaming features of LMSs could assign certificates or badges to learners based on their mastery of course content and could even be used to assign a rank or status to individual learners that could be shared within the user community.

Conclusion

Learning management systems (LMSs) have evolved in response to the demand for innovative educational products that leverage advances in information technology and telecommunications. LMSs can be either proprietary, where the client pays for the installation, maintenance, and end-user licensing, or open source, where the source code is freely available but the installation and maintenance is handled in-house. LMSs have many features that support online learning including course management, assessment, learner progress tracking, gradebook, communications, security, and smartphone access. LMSs continue to evolve, and future versions are likely to include tools and features that facilitate more tailored content to individual learners, enhance social interactions between online learners, and provide more timely and relevant analytics to institutional decision-makers.

► Learning Programming, Success Factors

Learning Programming, Student Motivation

Francisca A. Adamopoulos
School of BIT&L, RMIT University, Melbourne,
VIC, Australia

Student motivations have been extensively researched in general education; however, the topic has only been recently investigated in the

context of learning programming. The major themes emerging from current research are:

- Motivational factors are generally intrinsic or extrinsic.
- How relevant students see their learning to their future careers can influence their efforts.
- Some students are independent learners while others want to be taught.
- Self-efficacy can influence the learning effort.
- Students with growth mindsets are more likely to learn than those with fixed mindsets.
- How students react emotionally to their learning can also be an influence.

Motivational Factors

Motivation is a student's "willingness, need, desire and compulsion to participate in and be successful in the learning process" (Bomia et al. 1997). Motivational factors have been categorized into two broad groups: intrinsic and extrinsic.

Intrinsic motivation, also known as self-motivation, is the deep desire for learning of a subject area. It originates from within the person and is influenced by one's self-esteem, self-satisfaction, personal values, needs, and drives (Bomia et al. 1997; Jenkins 2001). It leads to a deeper learning approach and greater conceptual understanding and produces learning outcomes which are flexible and transferable (Entwistle 1998; Vansteenkiste et al. 2006).

With extrinsic motivation, behaviors are performed to satisfy an external demand or obtain an externally imposed reward. They may be done for their instrumental value and not merely for the enjoyment of the activity itself or for its intrinsic interest. Ryan and Deci (2000) describe a continuum of extrinsic motivations, where the motivation varies depending on the degree to which it is autonomous or self-determined. Five types of extrinsic motivation are described:

- *Amotivation (unwillingness)*: lack of an intention to act which may be from not valuing the activity, not feeling competent to do it, or not believing it will yield a desired outcome.

- *External regulation (passive compliance)*: behaviors are performed to satisfy an external demand or obtain an externally imposed reward.
- *Introjection*: behaviors are performed under pressure to avoid guilt or improve self-esteem.
- *Identification*: the person has identified the value of performing an activity and therefore has accepted its regulation as his or her own.
- *Integrated regulation*: the reasons for performing an action are further internalized and integrated to the self and become self-determined.

The stronger forms of extrinsic motivation involve a degree of autonomy with a feeling of choice and a sense of conviction, where subjects display an “attitude of willingness.” Weaker forms involve a mere compliance or external control where subjects are “externally propelled into action.” These weaker forms lead to a surface approach to learning and fear of failure and produce learning outcomes which are inflexible and not readily transferable (Entwistle 1998). Perceived competence, understanding, and the belief of possessing the skills to succeed help to internalize an extrinsic goal (Ryan and Deci 2000).

Other forms of extrinsic motivation include social motivation, which is based on the idea that the primary motivator is the desire to please some third party whose opinion is valued (Jenkins 2001). To some extent, social motivation might include fear of failure as a motivator (Biggs and Tang 2007).

Achievement motivation is based on the idea of doing well for personal satisfaction (Entwistle 1998). The student will adopt whatever strategy they believe will allow them to obtain the best results or highest marks (Jenkins 2001). Entwistle (1998) describes achievement motivation as being:

- Competitive, with the possibility of becoming egotistical and selfish
- Dependent on time management and organized studying
- Treating tasks as personal challenges

Within the context of learning programming, several studies have found that for most

programming students, achievement and extrinsic motivations were the dominant influences on their attitudes toward their studies (Jenkins 2001; Kori et al. 2016). Intrinsically motivated students, however, have been found to obtain higher programming results (Bergin and Reilly 2005a). Furthermore, students who have high levels of intrinsic motivation and task value use more meta-cognitive and resource management strategies (Bergin and Reilly 2005b; Bergin et al. 2005; Sheard et al. 2009). Attempts at using extrinsic motivations in teaching, such as rewards and student comparisons, seemed to have little impact on performance (Bergin and Reilly 2005a).

Several studies have looked at influences on motivation. Lack of skills when learning programming can cause motivation to change from intrinsic to extrinsic, while the presence of skills can increase motivation (Carbone 2007; Carbone et al. 2009). Multimedia arts students doing programming did not have a negative attitude to programming but did expect it to be difficult (Bennedsen 2003).

A number of studies have looked at using different technologies to motivate students to learn introductory programming. The use of digital badges in a Moodle-based introductory programming learning environment was found to be positive, although motivation levels varied among learners and over time (Facey-Shaw et al. 2015). Another study explored the use of mobile technology and social media as tools to support student interactions among themselves in their learning of programming (Maleko et al. 2012, 2014). Other studies have looked at using gamification-based learning platforms to motivate the learning of programming (Burguillo 2010; Fotaris et al. 2016; Swacha and Baszuro 2013).

Career Relevance

General educational research has shown that “when students see the relevance of what they are learning to solve problems and achieve tasks in the real world, especially in desirable occupations, students are more motivated to learn the material and are more engaged in school”

(Woolley et al. 2013). Relevance as a teaching strategy was found to promote a higher engagement and academic achievement (Keller 1987; Means et al. 1997). Studies on expectancy-value theories of motivation have found that the students' perception of the value of the lesson content is a key motivational factor because it influences the student use of cognitive and organizational strategies (Means et al. 1997; Pintrich 1999).

Learning interest orientations can be extrinsic such as students aiming to obtain a qualification which would lead to a job or intrinsic such as students seeking knowledge which would equip them well for their future careers (Beatty et al. 1997; Jenkins 2001). Even when students recognize what they are learning is relevant to their long-term future careers, however, they still may only be motivated to study content that is perceived to be immediately relevant (Lucas 2001). Career motivation and personal interest can coexist and mutually reinforce each other (Kember 2016).

How programming students see programming as relevant to their future careers may influence their motivation to learn programming. This topic, however, has not been extensively explored. Programming has traditionally been taught in Computer Science, where students are usually attracted to programming and intend to work in the IT field (Kinnunen et al. 2016).

A number of studies, however, have found that not all programming students necessarily want to become programmers. Curzon and Rix (1998) found that even students taking a second or third programming module viewed programming as "useful career-wise but only as a secondary skill." Another study found that some first year CS students described their future career plans as the desire to work in their own company, in small start-ups or as managers, rather than in a technical role (Kinnunen et al. 2016).

In a study of engineering students, some students were categorized as "conversational programmers," who did not necessarily want to be professional programmers but wanted to learn programming so that they could "speak the language and improve their perceived job marketability in the software industry" (Chilana et al.

2015). Even non-CS majors who enjoyed learning programming were found to dismiss it as not being applicable to their goals (Hewner and Guzdial 2008).

In a study of what motivates IT students to persist with their degree program, three factors were identified: previous personal contact with IT, the reputation of the IT field, and development (self-development and IT skills development) (Korii et al. 2016).

Various attempts have been made to change programming content and/or use technologies to make learning of programming more relevant to students. Games and web programming were used to illustrate how programming is a relevant skill that is used to solve real-world problems that the students perceive important to have for their future careers (Feldgen and Clua 2004).

A number of studies have attempted to teach programming with LEGO Mindstorms, with mixed results. McWhorter and O'Connor (2009) found that students were more motivated, but mostly for the content rather than relevance. Lykke et al. (2014) also found students more motivated and engaged, but they experienced frustration due to limitations of the robots.

With programming now being taught to a much wider range of students, a deeper understanding is needed of how these students perceive programming as relevant to their careers and how that influences their motivations.

Independence

The approach students take to their own learning has been described in various studies, mostly from the perspective of active/independent learning or passive/dependent learning.

Dependence has been described by Baird and Mitchell (1991) as a poor learning tendency where the learner, despite being keen to succeed, adopts a passive, dependent approach to learning. The learner assumes the role of "a passive recipient of information and instructions," expecting the teacher (or text) to tell them what to do and how to do it (Baird and Mitchell 1991; Carbone 2007).

In a study of programming students, dependence was highlighted as a deficit in generic skills by Carbone et al. (2009). When students got stuck, they sought assistance from experienced friends and tended to act on their suggestions, regardless of whether they had understood or not. One study that investigated student programming success from the instructor's perspective reported that teachers believe that success hinges on students taking responsibility for their learning and putting in sufficient effort (Kinnunen et al. 2007).

A model of "ownership of learning" is presented by Conley and French (2014) in their study of college readiness of students. "Students who own their own learning can go beyond simply following teacher directions. They are more likely to complete complex assignments, solve problems that require persistence, and create original or novel work of high quality" (Conley 2014; Conley and French 2014).

The Conley and French (2014) model of ownership of learning consists of:

- *Motivation and engagement*: Self-guided actions where the students see value in the coursework, are motivated to excel, are interested in the content, and enjoy a challenge.
 - *Goal orientation and self-direction*: Strategies to set academic goals and identify the resources and steps to attain them. This relies on the ability to exercise control over one's behavior.
 - *Self-efficacy and self-confidence*: Students' confidence in their ability to complete increasingly challenging and complex academic and career tasks.
 - *Metacognition and self-monitoring*: Awareness of the learning process, active participation in the learning, and reflecting on that participation.
 - *Persistence*: Related to resilience but also encompasses the notions of grit and academic tenacity.
- In a study of undergraduate student approaches in peer-led workshops in science, engineering, technology, and mathematics, three approaches to learning were identified (Micari and Light 2009):
- *Reliance* – Thinking about getting through the course:
 - Intentions: Reducing anxiety and confusion and gaining confidence and clarity
 - Constraints: Lack of confidence, self-discipline, and time management skills
 - *Engagement* – Thinking about engaging with the material:
 - Intentions: Reducing passivity and increasing involvement, applying rather than absorbing
 - Constraints: Watching rather than doing, knowing principles but not knowing how to apply them, only attempting basic problems, more help is required
 - *Independence* – Thinking about how to learn:
 - Intentions: Becoming a better learner, developing an integrated system for understanding
 - Constraints: Limited set of problem-solving tools, concepts stand alone
- Self-regulated learning (SRL) has been an important topic in the fields of education and psychology. SRL is defined as the degree to which learners are metacognitively, motivationally, and behaviorally active participants in their own learning (Zimmerman 2002). Studies have found SRL to have a significant positive correlation with academic achievement in elementary, high school, and college students (Bergin and Reilly 2006). One model of self-regulated learning includes the following components (Pintrich 1999):
- *Cognitive learning strategies*: include rehearsal, elaboration, and organizational strategies
 - *Metacognitive and self-regulatory strategies*:
 - Planning strategies – setting goals for studying and doing task analysis of the problem
 - Monitoring strategies – monitoring of comprehension using self-testing techniques
 - Regulation strategies – realign back to the goal when the learner realizes a breakdown in understanding, e.g., going back and rereading the text that is not understood.
 - *Resource management strategies*: controlling their time, effort, study environment, and other people such as peers and teachers through help-seeking strategies

- *Motivational beliefs*: include self-efficacy beliefs, task value beliefs, and goal orientations

The cognitive and metacognitive strategies represent the “skill” component, and the motivational beliefs represent the “will” component (Bergin and Reilly 2006).

Students who perform well in programming were found to use more meta-cognitive and resource management strategies than the lower-performing students (Bergin et al. 2005). Ott et al. (2015) attempted to improve student’s self-regulation during their learning by supplying them performance indicators at different stages of an introductory programming course. They found, however, that the students’ study behavior and learning outcome remained unaffected, despite them valuing the information.

In a study by Sheard et al. (2013), students described a range of independence in their learning behaviors and willingness to take responsibility for their own learning. Most students described some degree of independence by expressing a desire to work alone and understand better by themselves. In contrast, other students described a desire to be taught, while one student expressed preference for the type of teaching experienced in high school where students rely on their teachers (Sheard et al. 2013).

Self-Efficacy

Self-efficacy is a person’s perception of their own ability to succeed in a performance situation. Self-efficacy theory has been used as a tool to understand and promote intrinsic motivation (Bandura 1997, 2002). “A person who perceives themselves to have a low-level of self-efficacy will, despite having the necessary potential, ability and skill, not perform well at carrying out a task” (Bomia et al. 1997). Self-efficacy beliefs influence the choices a person makes, such as the degree of effort spent on a task, the level of persistence, and the response to obstacles (Bomia et al. 1997; Wiedenbeck et al. 2004).

There are four principal influences on self-efficacy (Bandura 1997, 2006; Lin 2016):

- *Mastery Experiences*: Repeated successes increase self-efficacy, while repeated failures reduce it.
- *Vicarious Experiences*: Observing similar peers succeed can increase expectations of success.
- *Social Persuasion*: If an individual is persuaded, they can complete a task and try harder.
- *Physiological State*: Levels of stress, tension, fatigue, mood, pain, etc. can impact self-efficacy.

Within the programming education context, a considerable number of studies have found a positive correlation between a student’s self-efficacy of programming and their performance in programming courses (Adair and Jaeger 2011; Altun and Mazman 2015; Bergin and Reilly 2005a, b, 2006; Gomes et al. 2012; Kanaparan 2016; Özmen and Altun 2014). In general, students who feel capable of writing programs tend to perform well, while students who feel they are not capable of writing programs perform poorly.

Similarly, studies have found a correlation between “comfort level” and performance (Cantwell-Wilson and Shrock 2001; Ventura 2005). Students that feel comfortable with their studies will perform better, while students who feel anxiety about learning programming will fare worse.

A number of factors have been found to influence self-efficacy, which in turn influences performance. Several studies have found that previous programming experience is linked to programming self-efficacy (Özmen and Altun 2014; Wiedenbeck 2005; Wiedenbeck et al. 2004). Another found that persistence levels had a significant effect on a student’s self-efficacy beliefs (Lin 2016). Students may also use comparisons with their classmates as a base for their self-efficacy perceptions (Kinnunen and Simon 2011).

Several studies have looked at gender influences on self-efficacy, with mixed results. Lin (2016) found no significant differences in self-efficacy between genders, while Beckwith et al. (2005) found females exhibited lower self-efficacy. Female students have also been found

to revise their self-efficacy beliefs earlier than males, which suggests early failures could cause female students to disengage from their studies (Lishinski et al. 2016).

Variations in self-efficacy have also been studied. Wiedenbeck et al. (2004) found that self-efficacy does increase substantially during an introductory programming course. Changes, however, are also not always straightforward. Students may reflect negatively on their self-efficacy after successfully completing an assignment or positively after struggling with an assignment (Kinnunen and Simon 2011, 2012).

Mindset

Mindset Theory has been developed by Dwek (2008), and others, over the past two decades and describes how a person's belief about their ability influences their response toward a goal (Cutts et al. 2010; Diener and Dweck 1980; Dweck 2000; Elliott and Dweck 1988; Robins and Pals 2002). Dwek (2008) describes two mindset frameworks:

- *Fixed Mindset (learnt helplessness)*

Failures are overestimated and seen as unavoidable, recurring, and unconquerable. Intelligence is seen as static so effort is placed in appearing smart rather developing skills. Failure is viewed as resulting from lack of intelligence with decreasing self-esteem, and the response to setbacks is to give up. The judgment of others and self is seen as important (Diener and Dweck 1980; Dwek 2008).

- *Growth Mindset (mastery orientation)*

Failures are seen as conquerable and avoidable and successes replicable. Intelligence can be developed, so effort and time are spent on developing skills. Failure is attributed to lack of effort, thus maintaining self-esteem. Learning and helping others learn are important (Diener and Dweck 1980; Dwek 2008).

Fixed mindset learners adopt performance-oriented goals, while growth mindset learners adopt learning-oriented goals (Elliott and Dweck 1988).

The learning tendencies of each type of mindset are summarized in Table 1 (Dwek 2008):

A number of studies have recognized the importance of self-theories (mindset) research and how this relates to and impacts the learning of programming. Programming students are confronted with an excessive amount of challenges and negative feedback when learning to program for the first time. Students with fixed mindsets are likely to adopt a helpless response to these innate challenges and view difficulties as a lack of ability or intelligence and disengage by practicing “risk avoidance and strategy abandonment” (Murphy and Thomas 2008).

A study by Cutts et al. (2010) implemented several mindset-based interventions: “tutors taught mindset to students; growth mindset feedback messages were given to students on their work; and, when stuck, students were encouraged to use a crib sheet with pathways to solve problems.” They found that these changes resulted in a significant change in mindset and improvement in test scores. They did recommend that since programming students come up against failure more often than in other subjects, the mindset message may need to be reinforced regularly (Cutts et al. 2010).

Hanks et al. (2009) asked students what advice they would give to future students to develop their growth mindset toward programming. Some of the advice noted by students included:

Learning Programming, Student Motivation, Table 1 Fixed and growth mindset tendencies (Dwek 2008)

	Growth mindset tendencies	Fixed mindset tendencies
Challenges	Are embraced	Are avoided
Obstacles	Are opportunities to learn and persist through	Acts defensive or gives up easily
Effort	Is a path to mastery	Is viewed as fruitless
Criticism	All criticism is constructive, to be learnt from	Perceived as negative, ignored even if useful
Success of others	Offer lessons and inspirations	Feels threatened by it
Result	Reach “ever-higher” levels of achievement	Plateaus early achieving below full potential

- *Make the most of the class*: Clear doubts immediately and get help when you need it. It is very hard to catch up in programming if you fall behind. Programming is cumulative.
- *Learn from mistakes*: The key to understanding is using each error as a stepping stone to learn and understand why the error occurred. “Everybody makes mistakes – learn from them.”
- *Learn from others*: “if you cannot work out your mistake, find someone to help you, or discuss with your friends.”
- *You have to program to learn*: “After solving a problem, change the code and play around with it. Experimenting is the best way to learn.”
- *Have a plan*: (1) “Read through the descriptions of the program, and make sure you know what you are supposed to do”. (2) Make a flow chart. (3) Write the program step by step.
- *Don’t be intimidated*: “Don’t be afraid of asking questions in class” – “Do not worry about looking stupid for not knowing” – “other students may be wondering the same thing”
- *Programming can be fun*: Learning programming is a challenge but also an opportunity. Programming is fun when you start to know it (Hanks et al. 2009).

Mindsets may also be domain specific. Scott and Ghinea (2014) found that students’ mindset for programming aptitude was different to their mindset about intelligence. Educators, therefore, should focus specifically on promoting growth mindsets for programming.

Studies have also looked at the relationship between self-theories (mindsets) with resilience and grit (passion and perseverance to pursue a goal over a period of years). Mindsets have been found to influence resilience (Scott and Ghinea 2014; Yeager and Dweck 2012). A study of high school students by Kench et al. (2016) found a weak correlation between mindset and grit.

Emotions

Some recent studies have tried to understand student emotional experiences when learning to

program. A study by Kinnunen and Simon (2010) investigated students’ emotional experience with and reactions to programming assignments. They identified emotions at six stages of the programming experience:

- *Getting started*: “It’s Greek to me,” “OK, what now?”
- *Encountering difficulties*: Hit by lightning experience, rapid change experience.
- *Dealing with difficulties*: Feedback-guided experience, Hamster wheel experience, course-specific experience, other computing factors experience.
- *Overarching*: Life outside this assignment experience, helping others experience.
- *Auxiliary emotional load*: Impact of outside factors.
- *Self-efficacy experience*: At all stages, there were emotional consequences from students assessing their ability compared to others or to academic success.

One category highlighted in their findings was the “hit by lightning” experience, which they labelled as the mark of the utter novice. This is where a student encounters a problem that comes out of blue, impacts their confidence, and leaves them with little idea of what is wrong or how to fix it (Kinnunen and Simon 2010).

Bosch et al. (2013) got students to self-report their emotions during programming learning sessions. They found that the most common emotions students experienced were flow/engaged (23%), confusion (22%), frustration (14%), and boredom (12%). On the other hand, curiosity, happiness, anxiety, surprise, anger, disgust, and fear were rare. Chetty and van der Westhuizen (2013) found that novice students experience strong oscillating emotions while learning to program, especially when learning threshold concepts.

Summary

Recent research into programming student motivations has given important insights, but more exploration is necessary. With programming now

being taught to a much wider range of students, a deeper understanding is needed of how these students perceive programming as relevant to their careers and how that influences their motivations. With much of the learning now happening beyond the classroom, a deeper understanding is also needed of how independent and dependant learning impacts student learning of programming.

[Cognitive styles in programming](#); [Demographics](#); [Learning influences](#); [Learning influences in programming](#); [Learning programming](#); [Literature review](#); [Previous programming experience](#); [Previous studies](#); [Success factors](#)

There has been considerable research in computer science education looking at factors that impact on students' performance in introductory programming courses. Researchers have sought to identify one or more attributes that could be used to predict and/or influence student success in learning to program. The major themes emerging from current research are:

- Cognitive and learning styles
- Programming experience prior to university entrance
- Previous education (such as math scores)
- Stage in degree and degree major
- A range of demographic discriminating factors

Cognitive Styles and Learning Styles

Cognitive styles and personality is defined as the “individual differences in organizing information, and processing both information and experience” (Bishop-Clark 1995). Cognitive styles and personality variables have been studied as factors that may correlate with programming success.

Field independence and high reflectivity have been shown to be positively related to programming achievement (Bishop-Clark 1995). A field independent person is better at identifying and isolating relevant information from a complex situation, imposing their own structure/organization to the material. Field independence should also be encouraged through teaching (Mancy and Reid 2004).

Studies that have looked at the learning styles/cognitive profile groups described by Krause (2000) found that intuitive thinkers have tended to perform better in programming than sensor feelers (Prasad and Fielden 2002; Woszczyński et al. 2004). Intuitive learners use visual memory cues to trigger retention of information. Thinkers like to have concrete evidence or information to make decisions.

Reflective and verbal learning styles outperformed the active visual ones when correlated with programming performance (Allert 2004). “Students who perform well in programming use more meta-cognitive and resource management strategies than lower performing students” (Bergin et al. 2005).

A number of literature reviews looking at cognitive styles and personality traits have found that while studies do show correlations between factors and performance, they are inconsistent in explaining individual differences and offer little predictive power (Bishop-Clark 1995; Robins 2010; Ventura 2005).

As the different programming phases involve different skills, Bishop-Clark (1995) suggested relating cognitive styles to each distinct phase of programming.

Programming Experience Prior to University Entrance

Various studies have found that students with previous programming experience tend to perform better in programming courses than those students with no previous programming knowledge (Cantwell-Wilson and Shrock 2001; Chinn et al. 2010; Gomes and Mendes 2008; Hagan and Markham 2000; Holden and Weeden 2003, 2004, 2006; Kori et al. 2016). The more languages they already know, the better they perform (Hagan and Markham 2000), but the benefit tends to be more on the first programming course than subsequent courses (Holden and Weeden 2004).

A number of studies have found that previous programming experience influences student’s self-efficacy which, in turn, positively influences performance (Özmen and Altun 2014; Wiedenbeck 2005; Wiedenbeck et al. 2004). In particular, Wiedenbeck (2005) suggests that it is the knowledge organization that directly influences success and strengthens post self-efficacy.

Other studies, however, have found little or no correlation between previous programming experience and student grades (Allert 2004; Bergin and Reilly 2006; Bergin et al. 2005; Murphy et al. 2006; Pillay and Jugoo 2005; Ventura 2005; Ventura and Ramamurthy 2004).

On the whole, previous studies have shown that students with previous programming experience will tend to perform better in learning programming than students with no previous experience.

Previous Studies

A range of previous studies have explored the relationship between grades from high school, or

other previous studies, and student performance in computing degrees, and programming courses in particular. The majority of the focus has been student's previous grades in maths and science, with mixed findings.

A number of studies have found a positive correlation between student's mathematical aptitude and high school scores in maths/science with their performance in programming courses (Altun and Mazman 2015; Bergin and Reilly 2005, 2006; Byrne and Lyons 2001; Cantwell-Wilson and Shrock 2001). Other studies found high school math grades to be a clear moderate positive indicator of success in first year programming courses (Bennedsen and Caspersen 2005; Gomes and Mendes 2008; Qahmash et al. 2015).

Other studies, however, have found that previous grades have little bearing on success in computer science and programming (Boyle et al. 2002). Ventura (2005) found SAT scores offered little predictive value, and Alexander et al. (2003) reported that while good grades may predict good performance in mathematics units, they found "nothing in entry qualifications to indicate which students will be successful in the study of programming."

Stage in Degree and Degree Major

The majority of studies on learning programming have tended to focus on the first programming courses only (Beise et al. 2003). The studies that have looked at two or more programming courses in the programming sequence suggest that a better understanding of the basic concepts of sequence, iteration, and decision occurs during or by the end of the second course (Gomes and Mendes 2008; Sheard et al. 2009; Tew et al. 2005). The more advanced concepts can then be learnt more easily once students have mastered how to problem solve and have an understanding of basic concepts (Holden and Weeden 2004; Robins 2010).

No correlation has been found between the year level of students and the results of introductory programming courses (Bennedsen and

Caspersen 2005; Rountree et al. 2002). The situation is complicated by non-computing major students doing programming in later years or treating a programming course as a "filler" (Rountree et al. 2002).

Various studies have also looked at degree majors and minors as a potential predictive factor of success. The intended major of computer science students has not been found to be a significant factor in programming learning outcomes (Bennedsen and Caspersen 2005; Rountree et al. 2002).

Computer science majors have been found to have a higher probability of passing the first programming course than information systems majors (Beise et al. 2003). A number of studies have reported that efforts in tailoring programming courses for non-CS majors, such as information systems students, have led to higher pass rates (Forte and Guzdial 2005; Yadin 2014; Yadin and Or-Bach 2008).

Demographics

The influence of gender on programming outcomes has had considerable research interest, and to a lesser extent, age.

Gender

The issue of gender imbalance in the field of computing degrees due to the steady decline of female graduates in this field, particularly in the USA, the UK, and other western countries, has been noted by many studies (Sinclair and Kalvala 2015).

Females, however, have been widely found to perform just as well as males, with many studies finding no correlation between gender and programming learning outcomes (Beise et al. 2003; Bennedsen and Caspersen 2005; Byrne and Lyons 2001; Chinn et al. 2010; Pillay and Jugoo 2005; Rountree et al. 2002; Ventura and Ramamurthy 2004). Although females may start their computing degrees with less previous programming experience than their male counterparts, by the

end of their introductory courses, they catch up, achieving similar levels of mastery of programming concepts as the males (Murphy et al. 2006).

Gender differences have, however, been found in student perceptions and attitudes toward learning programming. Male students have been shown to perceive programming as being easier and have a higher intention to program in the future, compared to female students (Rubio et al. 2015).

Female students have been found to be less confident with their skills (Carter and Jenkins 2001) and less comfortable than male students asking questions in class and interacting with their instructor (Alvarado et al. 2017; Sinclair and Kalvala 2015). These differences were even found to be consistent or increase across course levels (Alvarado et al. 2017). Female students have also been found to revise their self-efficacy beliefs earlier than males, which suggest early failures could cause female students to disengage from their studies (Lishinski et al. 2016).

Several studies have also found that female students tend to work more with others and study more with their peers, compared to male students (Chinn et al. 2010; Sinclair and Kalvala 2015). Pair programming was found to be beneficial to help female students build their self-confidence toward learning programming (Carter et al. 2011).

Age

Relatively few studies have looked at student age as a predictor of programming success (Rountree et al. 2002). Those that have studied it have looked at age in combination with other factors and have found that it was not a good predictor of success in programming learning outcomes (Beise et al. 2003; Bergin and Reilly 2005; Rountree et al. 2004; Woszczynski et al. 2005a; Woszczynski et al. 2005b).

Other Factors

Various studies have looked at a wide range of other factors as potential predictors of success in

learning programming. Some of these have included:

- *Involvement in Computer and Video Gaming* was found to be a negative influence on success (Allert 2004; Cantwell-Wilson and Shrock 2001).
- *Attribution to Luck* was also a negative influence (Cantwell-Wilson and Shrock 2001).
- *Resource Management Strategies* are a positive influence (Bergin and Reilly 2005)
- *The Grade the Student Expected to Achieve* at the beginning of the course was the strongest single factor indicative of success (Rountree et al. 2002).
- *The Student's Perception of Their Understanding* of the module was strongly correlated with performance (Bergin and Reilly 2005).
- *Ability to Articulate an Algorithm* in depth and map-drawing style (Simon et al. 2006).
- *Abstraction Ability* had conflicting findings (Sheard et al. 2009). Bennedssen and Caspersen (2008) found no correlation, while Murphy et al. (2005) found that better performing students are more able to express abstract concepts. Students have also been found to think more abstractly as they progress through their programming course (Perrenet and Kaasenbrood 2006).
- *Programming Behaviour Based on Event Pairing* from compilation log data during lab classes showed strong correlation with programming performance (Watson et al. 2014).

Summary

Despite considerable research into success factors over many years, no single factor has been found to provide a clear determinant of success. The experience students go through in learning programming is complex and needs to be studied in depth. The real picture is best summarized by Sheard et al. (2009): “given enough time, clear direction, and instruction, students will succeed in programming.”

Introduction

Lecturers are always intrigued with how and what students learn inside and outside the classroom. This is essential to make sure that students are actively engaged in learning inside the classroom and in comprehending the whole session. As a complement, it is also as important to know students' ways of learning at home. One stream of research argues that any student employing cognitive strategies and organizing her or himself at a high level would have a direct impact on their achievements (Ersözülü 2010). Cabi and Yalcinalp (2012) highlighted that students' awareness about their own styles and their ability to choose and use the most appropriate strategies for themselves are two important factors for their success. In this regard, students need to develop sound strategies to increase their learning effectiveness and to excel (Zimmerman 1994) and be an independent learner as well (Ersözülü 2010). In their review of the literature, Beckers et al. (2016) reported that modern students are supposed to be self-directed learners, learn how to build and use networks,

cooperate with others, and use information and communication technology (ICT) to find appropriate information. More recently, the term STEM emerged to denote for a curriculum based on science, technology, engineering, and mathematics teaching in an interdisciplinary and integrated manner. This further aggravates the learning process for the learner. Thus, the challenging task of identifying the different predictors of academic performance could shed more light into the learning process (Mitrofanu and Iona 2013). Learning strategies can be defined as "behaviors and thoughts in which a learner engages and which are intended to influence the learner's encoding process" (Michou et al. 2013: 3). They are perceived as a schematic structure in the form of a chain of learning activities performed by the learner to get hold of new information (Ersözülü 2010), thus affecting the way a learner selects, acquires, organizes, or integrates new knowledge (Weinstein and Mayer 1983). Strategy is like an arrangement to achieve something or employment of a plan that is developed to reach a goal (Zimmerman 1994). Teachers attempt to teach students what and how to learn, remember, think, and motivate themselves (Weinstein and Mayer 1983). Thus, learning strategies cover both cognitive and metacognitive and affective strategies (Ersözülü 2010). Therefore, it is important to know what drives learning. Those are the features that keep students continue working to fulfill their objectives (Lynn 2009).

In a review of the literature (Lynn 2009), the following implications were highlighted. Initially, meeting the diverse needs of different higher-education students in general and STEM students more specifically represents a challenge for teachers. Secondly, the introduction of technological tools in education did help but in part as identifying students' individual differences, and their learning needs should come first. Stemming from these perspectives, this research is interested in focusing at different learning strategies and explaining their impact on IT student learning. It is clear that this topic is vast and spans different

contexts and disciplines. Accordingly, the following research question is posited: *how can UAEU IT students acquire lifelong effective learning strategies*. This leads to the following sub-questions and expected objectives:

- i. What are the possible impacting factors or models of student learning strategies?
- ii. How those factors impact IT student learning strategies.
- iii. How to help UAEU IT students enhance their learning strategies.

Thus, the purpose of this research is to identify the different learning strategies followed by students. Then the research will discuss the importance of such strategies as applied on UAEU IT students. We leave the comparison between the research findings and other non-IT students to a future research that will follow the current phase. Hence, the term students or UAEU students is used henceforth to denote for findings pertaining to UAEU IT students.

Determinants of Learning

Fook and Sidhu (2015) research investigates learning challenges faced by students in higher education. Their findings showed the following eight main learning challenges faced by students in higher education: cognitive challenge, becoming an active learner, coping with reading materials, instructional problem, language barrier, time management, burden of assignments, and culture difference in higher education. Alhija and Nasser (2016) investigated the impact of five teaching dimensions: goals to be achieved, long-term student development, teaching methods, relations with students, and assessment. She indicated that students perceived assessment as the most important of the five teaching dimensions and long-term student development as least important. Only gender and field of study made a salient difference in students' perceptions of good teaching. Fook and Sidhu (2015) suggested that higher learning institutes should emphasize on the construction of knowledge through active interaction between

the lecturer and the students which became a platform for the students to cope up with the learning challenges they were facing in higher education. Cabi and Yalcinalp (2012) highlighted that the learner styles of students are indicated as the total of four fundamental learning types:

1. Accommodator: Participate in real experiences and prefer learning based on exploration and application and searching. They are open to strange ideas.
2. Divergent: They prefer learning by observing real experiences instead of participating in them. They wish the systematic presentation of the knowledge on the related topic.
3. Converger: Details are very important for those individuals, and they try to understand the whole by studying each part first. They learn for the new knowledge first and then apply it. They are not afraid of making mistakes while learning.
4. Assimilator: They prefer structured and systematic knowledge. Presented knowledge must be detailed and structured and must have visual and audio components.

Cabi and Yalcinalp (2012) found that assimilator learning style was the most adopted by students, and gender has no significant effect on learning styles and no apparent significant effect of learning strategies on learning style of students.

According to the literature review in this research, six factors were identified to influence students' learning strategies and their academic achievement (AA).

Student Motivation

Motivation can be considered as student's needs, wants, interests, and desires to participate in the learning process to excel in his/her AA (Lynn 2009). Motivated student shows great desire, drive, or emotion to participate in the learning process, and it is directly related to academic success unless there is a problem with cognitive skills (Lynn 2009). Wolters (1999) found that the importance of motivational self-regulation strategies could be revealed by finding a positive relationship between students' use of these strategies and indicators of

their cognitive engagement, effort, and classroom performance. He contended that models of self-regulated learning may need to be upgraded to include more directly students' purposeful control of their behavior or thinking for the purpose of impacting their effort and tenacity in fulfilling their different tasks. In a review of the literature (Lynn 2009), three main motives of learning emerge, surface (memorizing), deep (understanding), and competitive, where each motive entails adopting a different learning strategy.

Time-Poorness

Time perspective in academia and industry has proved to be a good predictor of students' learning behavior and academic achievement. Time-poor students feel pressurized as they feel they lack the time to complete their learning activities, and this puts high cognitive and metacognitive demands on students (Lynn 2009). They tend to engage in surface rather than deep learning. Managing time has been associated with better learning performance. Many students find themselves unable to spend as much time on their studies because they have part-time or even full-time work and because of family commitments (Lynn 2009). It is not a matter of having more time to finish a lengthy task; rather, utilizing better time management techniques could allow for the completion of the task within adequate time. Such techniques involve making to-do-lists, priority lists, and task to complete daily and dividing the task to smaller pieces (Koçak and Bayır 2009).

Mastery Effort

Effort can be defined as the amount of time spent on studying [1]. Also, effort refers to whether a student tries hard, asks for help, and/or contributes in the class. Studies of student effort propose that the more difficult a task appears, the less likely it is that the student will be motivated to take the task on. However, studies of student effort also propose that effort is linked with achieving well on a task. Therefore, students might be expected to find out what they need to study, study it, and be successful – if they have the ability to do the assigned task, confidence in this ability, and no concern about the task (Graham 2006).

Assessment Focus

Goal focus or assessment focus (Lynn 2009) is defined as information provided by an agent (e.g., teacher, peer, book, parent, self, and experience) regarding what the agent believed was important and what was required by the assessment procedure (Wolters 1999). In this regard, students consider highly the assessment requirements and making sure that in the game of learning, the lecturer holds the key to their success (Lynn 2009). On the other hand, when the teacher clearly specified the assessment requirements, students were more comfortable and focused on signs and other information given by the lecturer about what counts as important material and what would be in the examination. The same researchers believed that achieving what the lecturer wanted is an important strategy for success (Lynn 2009). Assessment focus affects what and how students learn, student motivation, and sense of well-being (Kinga et al. 2012). If used appropriately, assessment could substantially improve learning but that, most of the time, the impact of assessment practices was to limit, and even to reduce, student learning. It was only recently that researchers started to realize that using assessment as an integral part of instruction could improve learning outcomes for students, and at the same time, attempts were made to connect classroom practice to related bodies of research, notably feedback, motivation, attribution, and self-regulated learning (Kinga et al. 2012).

Competitiveness

Competition is a contest between individuals or groups. It arises when two or more parties strive for a goal. The person who wants to win the competition thinks creatively and works for doing the best (Koçak and Bayır 2009). Competitiveness has usually been viewed as a negative trait as it leads to suboptimal outcomes. However, other research indicated that competitiveness may hold different meanings for people from individualist and collectivist cultures. More specifically, some research viewed competition as something that can lead to self-improvement and personal growth (Vedel 2014).

Listening

Sight and sound and touch are considered important in learning (Lynn 2009). Listening is a passive skill that students could acquire spontaneously during classroom activities. In a listening activity, some students like to listen to the text once or twice to understand and hold more information (Bekleyen 2009). In a listening process, the listener must use a wider variety of knowledge sources, linguistic and nonlinguistic, to understand and take the incoming information (Graham 2006).

Case Background

Information about UAE's society [UAEInteract.com]. Information about United Arab Emirates University (UAEU) could be found at UAEU.ac.ae, and the university is located in Al Ain city and was established in 1976 and is the first comprehensive national (federal) university in the United Arab Emirates. Al Ain city is the second largest city in the Emirate of Abu Dhabi and the fourth largest city in the United Arab Emirates. It is located approximately 160 km east of the capital Abu Dhabi and about 120 km south of Dubai. Al Ain has the country's highest number of Emirati nationals.

UAEU has nine colleges. UAEU is currently ranked the number 1 research university among other Gulf countries and number 2 in the Arab World and number 385 globally. The total number of faculty members in the university during the academic year 2013–2014 was 644, in addition to a number of visiting faculty. There were 14,024 students registered at the university during the academic year 2013/2014. Enrolled male students represented 23%, while female students represented 77% of the entire student population.

As UAEU is a federal university, it serves all the Emirates in UAE, but in the past few years, most of the Emirates had their own local and federal universities and institutions, and accordingly, the UAEU coverage started to be limited to few Emirates as the research results show and suggest (below). Due to the considerable distances between the different Emirates and

according to UAE's strong tribal system (culture and traditions) and Islamic beliefs, this puts limitations on the free movement of females. Of course, this is for the sake of protecting and preserving them.

Accordingly, UAEU is pledged to provide complex network of transportation means (UAEU busses and cars and even air transportation) to safely transport male but mostly (larger proportion) female students between Al Ain city and the different Emirates/cities/islands each weekend and during other formal holidays. UAEU provides internal hostels with free full boarding and catering for both male and female students during the academic year. Female students (from outside Al Ain city) inside the hostel are confined to its premises and to the female side of UAEU campus. There is no intermingling between male and female students in the campus, and accordingly, the UAEU campus is split almost identically to separate between male and female sides. However, UAEU provides state-of-the-art social, sporting, and entertainment facilities to enrich the lives of both male and female students.

Findings and Analyses

As shown in Table 1, the majority of respondents came from the College of IT (CIT). The majority of respondents were singles (87%), females

Learning Strategies and Achievement of IT Students in Higher Education, Table 1 Distribution of responses across different colleges in UAEU

College	Frequency	Percent
College of IT	130	72.6
College of Science	20	11.2
College of Engineering	3	1.7
College of Education	1	0.6
College of Humanities and Social Sciences	13	7.3
College of law	2	1.1
College of Business and Economics	9	5.0
College of Medicine and Health Sciences	1	0.6
Total	179	100.0

Learning Strategies and Achievement of IT Students in Higher Education, Table 2 Distribution of responses across different Emirates in UAEU

Emirate	Frequency	Percent
Abu Dhabi and Al Ain cities	71	39.7
Dubai	5	2.8
Sharjah	31	17.3
Ajman	8	4.5
Ras Al Khaimah	27	15.1
Fujairah	36	20.1
Umm Al Quwain	1	0.6
Total	179	100.0

(90%), and UAE citizens (98%), and the remainder were from other Arab origins. Most of the responses came from students in their second (22.3%) third (19.0%), fourth (26.8%), and fifth (13.4%) year in UAEU. All respondents owned a laptop.

As shown in Table 2, the majority of UAE respondents came from the Emirate of Abu Dhabi and Al Ain city (39.7%) followed by Fujairah (20.1%), Sharjah (17.3%), and Ras Al Khaimah (RAK) (15.1%).

Motivation

Motiv3, 4, 5, 6, 7, and 8 (as ordered in Appendix 1) scored relatively the highest in this context (Table 3). This indicates that students resort to reminding themselves about the importance of getting good grades, to push their limits to see if they can do better, work hard in order to learn, try to become good at what they are learning or doing, and study at times when they can be more focused. It is interesting to know about the mechanisms put in place by students in order to act upon such motivating issues. It is also worth investigating whether such views were sporadic or as a result of a continuous effort (i.e., lifelong learning). In the second set of views, it shows that UAEU students try to make university work more enjoyable by focusing on the fun part of it, try to relate the materials to their life activities, and get rid of distractions that arise around them but more at a moderate level.

In line with the above discussions, students had a lower view of the enjoyability of their courses and the detachment of such courses from their

Overall averages	3.32	1.11

Overall, the research findings suggested that UAEU's students are moderately time-poor

real-world settings. This is an interesting contrast between the two sets of views which show a void between what the students learn in the classroom and the outside world. This calls for extending surrogates to what is being taught to students and attempt to link it more with the outside world.

Time-Poorness

The items of this factor scored moderately above the average on the 5-point Likert-scale (Table 4) and hence, agreeing that time-poorness impact their learning negatively. This is due to not having enough time to study, work and family commitments, and not putting sufficient time to understand what they read. It would be interesting to investigate student's teaching load at each semester and whether this load is adequate and balanced or not and also to investigate student's time utilization in studying inside (usually in UAEU's internal hostel) and outside the campus and between students living inside and outside Al Ain city.

It is worth noting that UAE nationals have strong social system and ties, and hence, all members including students are actively engaged in this system.

Mastery Effort

Student responses showed overall modest effort (Table 5). As per the measures, students understand the things that seemed to be difficult at the beginning, are being strict in their studying habits and more dependent on the illustrative course slides than any other learning tools, and understand the assessment requirements earlier on in the course. It is interesting to correlate such items with student's GPA by any future study. On the other hand, students spent less effort on reviewing the additional readings, as suggested by the lecturer; and they did not rely on the prescribed textbooks in studying (Effort2 and 4 scored the lowest). The above contrasts may suggest a separation between students' habits of learning and their actual learning which is limited to the course's slides. For example, students viewing themselves as strict in their studying habits may contradict with the depth level of such studies. This is worth for further investigation by any future research.

Assessment Focus

According to the high scores in Table 6, most UAEU students pay close attention to information that the lecturer provides about exams, they scout out for any hints, and they try to keep in mind exactly what a particular lecturer want when working on assignments. The suggested high

Competi3	3.00	1.213
Overall averages	3.82	1.018

assessment driven here such as showing consistent ambitious attitude at the student's side in order to pass and to excel in the different assessments, but according to the above suggested contrasts, may advocate a possible void between what is happening inside and outside the classroom. The fear here is that UAEU students are more concerned with merely passing a corresponding course than learning per se. This predisposition is worth of further investigation as well.

Competitiveness

From the high averages in Table 7, it shows that UAEU students seek to get high grades in their studies to get the best job and see themselves as ambitious. They were almost neutral on prospering financially. Interestingly, being ambitious came after attempting to get high grades and best jobs. Another interesting finding here is that financial incentives were not the main driver to obtain a university degree. These findings are worth for further investigation.

Listening

According to Table 8, the highest scores (Listen3 and 5) showed that students would understand better if the lecturer explains things rather than reading about them and prefer listening to the lecturer than reading textbooks (as endorsed above). This shows a strong propensity by UAEU students

Learning Strategies and Achievement of IT Students in Higher Education, Table 8 Listening

Item	Mean	Std. deviation
Listen5	4.47	0.837
Listen3	3.96	1.054
Listen4	3.58	1.170
Listen1	3.46	0.967
Listen2	3.45	0.961
Overall averages	3.78	0.998

to rely more on the lecturer's explanations than reading the course's textbook. Thus, the listening aspect was more effective if students hear explanations rather than reading the prescribed textbook. It is important to measure students' recollection of what they hear and learn in the classroom by any future research vis-à-vis literature on cognitive capability and absorption capacity. Although listening is important in learning, this is not sufficient to effectively learn and remember the explained material during classroom meetings.

The above discussion about relying on the course's slides and less on the textbook for learning may suggest a weakness in learning in general and their reading capabilities in particular among the surveyed sample. This could be attributed to time-poorness or to weakness in the English language, e.g., a fear or discomfort in reading a large number of English scripts and chapters. These important assertions are worth for further investigations.

Finally, Table 9 shows the overall means of the different items in this research. It could be argued here that overall, assessment focus, motivation, competitiveness, and listening, respectively, were the most important strategies adopted by UAEU students. Time-poorness was not a big problem, but mastery effort needed to be boosted among UAEU students.

Discussion and Conclusion

This research was developed with a focus to understand student learning strategies in UAEU. This research reviewed relevant literature in pedagogy and developed a framework that highlighted important learning strategies. The potential impact of each variable on student's

Learning Strategies and Achievement of IT Students in Higher Education, Table 9 Overall means of the different items

Item	Mean	Std. deviation

learning strategies is examined using a survey questionnaire. And Table 10 summarizes the research findings and implications.

This research has theoretical as well professional contributions and contentions. At the professional level, different suggestions were made to enhance students learning strategies within UAEU (Table 10). At the theoretical level, initially, this research generated further insights pertaining to UAEU students' learning habits. Although it was not possible to elucidate the significance of the research factors on student's success as such, the suggested factors and explanations shed interesting insights and contrasts at the same time on UAEU students' learning strategies.

Overall, the research findings suggested that the learning strategies of UAEU students were modest. The highlighted contrasting views and the dominance of most responses around the mean further suggested this posture. This could be attributed to personal as well as to cultural reasons as hypothesized in many parts in this research. Being a lecturer in CIT, one of the researchers admits his bias in suggesting many of the explanations and suggested propositions. Many of the suggested improvements could be achieved by designing programs aiming at enhancing student's learning capabilities and strategies. However, it is the cultural aspects that are more difficult to unveil and address.

Learning Strategies and Achievement of IT Students in Higher Education, Table 10 Research findings and implications

#	Factor	Findings	Implications and suggestions
1	Student motivation	UAEU's students are motivated	In line with the above, adding the enjoyability component into learning in the classroom is important. For example, edutainment emerged as a recent notion to promote learning while playing a game. Capitalize on student motivation issues by coaching students about how to exploit such forces to their learning and excellence through seminars and workshops. Providing links to courses from real-life events (local and international) could assist such students' link theory with practice (i.e., case studies, site visit as integral component of course design) conducting a review of such courses could further help in this regard.
2	Time-poorness	UAEU's students are almost time-poor	It is worth reviewing students' loads each semester and whether they have sufficient time to cover all courses adequately. Providing workshops on time planning and management should warrant against such wastage of time. Endorsing more community bonding should engage the families of students in their learning by freeing them to focus on their studies.
3	Mastery effort	UAEU's students are of modest mastery effort	Capitalize on student eagerness to learn by coaching students about how to exploit such forces to their learning and excellence through seminars and workshops. Encourage the use of other learning material in addition to the course slides. For example, highlight that exams will come from the book, beyond the slides' content.
4	Assessment focus	UAEU's students are more assessment-focused	Capitalize on this factor as one main driver for learning.
5	Competitiveness	UAEU's students are competitive	Attempt to tie self-ambitions with achievements and excellence and financial rewards through training and seminars. This should take place at the beginning of students' enrollment at the university and should be continuously be reminded throughout their academic years.
6	Listening	UAEU's students prefer listening than reading	Encourage reading by boosting the capabilities of students in the English language and maybe through creating reading clubs and/or competitions for reading/writing English texts (i.e., best essay, paper, etc.)

Cultural issues require the cooperation and collaboration of the overall community surrounding learning in general within UAEU in general and the family in particular.

Secondly, as suggested here, it is worth investigating the possible overlap between the different factors in general and between motivation and mastery effort in particular by any future research. For example, the possible interrelationships between motivation and mastery effort may impact learning in a different way as highlighted in this research.

The expected outcome of this research will be of importance to researchers, professionals, and policymakers interested in addressing weak and

strong learning strategies. This is an initial research in this area in UAE, and indeed, other researchers and universities maybe interested to understand the learning strategies of their students. Researchers could further use the suggested factors or add to them and test their significance on their contexts. Professionals would capitalize on many of the implications in this research (Table 10) to design and offer training programs and workshops aimed at students and officials in universities and elsewhere. Policymakers could consider many of the suggestion made in this research to devise effective policies to enhance student learning strategies.

Appendix 1 The Survey Questions

Motivation 1. Make university work enjoyable by focusing on something about it that is fun 2. Try to find ways that the material relates to my life 3. Remind myself about how important it is to get good grades 4. Push myself to see if I can do better than I have done before 5. Persuade myself to work hard just for the sake of learning 6. Challenge myself to complete the work and learn as much as possible 7. Think about trying to become good at what we are learning or doing 8. Try to study at a time when I can be more focused 9. Try to get rid of any distractions that are around me	Time-poorness 1. Don't have enough time to do as much study as I need to for my course 2. Other things such as work and family do not leave me enough time to think about the ideas from my studies 3. Often I don't have enough time to really understand the ideas I read about Assessment focus 1. Pay close attention to information the lecturer gives about exams 2. Lecturers sometimes indicate what is likely to be in the exams, so I look out for hints 3. Take care to find as much information as possible on what will be in an exam 4. When working on an assignment, I try to keep in mind exactly what the particular lecturer seems to want
Mastery effort 1. Try to be strict with myself in my study habits, so that I can do the very best I can 2. Look at most of the additional readings suggested by the lecturer 3. Limit my studying to the slides only 4. Use the prescribed textbook in my study 5. Make sure I clearly understand the assessment requirements early in the course 6. Usually set out to understand thoroughly the meaning of what I am asked to read 7. Usually put a lot of effort into trying to understand things that at first seem difficult	Competitiveness 1. Want high grades in my studies so that I will be able to select from among the best jobs available 2. See myself as an ambitious person 3. The main benefit of a university education is that it will enable me to earn more money Listening 1. Remember best things that are spoken 2. Remember best what I hear 3. Prefer listening to the lecturer than reading textbooks 4. Prefer listening than reading 5. Understand better if the lecturer explains things rather than reading about them

²Faculty of Education, Centre for Media Pedagogy, University of Lapland, Rovaniemi, Finland

Introduction

In the field of healthcare, a strong connection between education and real-life work contexts has been common for a long time. The oldest replications of the real world are anatomical models, part-task trainers, and role-playing (Nehring and Lashley 2009; Rosen 2008), and the medical field was among the first to apply simulation in education (Helle and Säljö 2012). Innovations in other industries, such as

technology and plastics, have made it possible to create more advanced simulators, such as high-fidelity patient simulators, games, and virtual realities (Rosen 2008). In the past two decades, the use of and research into simulation have grown rapidly. The aim of simulation-based healthcare education is to improve the quality of patient care and patient safety (Rall and Dieckmann 2005).

Existing empirical knowledge confirms the effectiveness of simulation-based education (Cook et al. 2011). Numerous studies have also shown that learners enjoy this type of learning (Brewer 2011; Konia and Yao 2013; Weller 2004), because it is learner-centered, experiential, and active learning mode. In addition, learning processes take place in safe environments. Participants can be taught many of the skills needed in working life, including clinical skills (Beauchesne and Douglas 2011) and theoretical knowledge (Chakravarthy et al. 2011), but most importantly with simulations, participants can learn many general competencies, including critical thinking, decision-making, problem-solving, and communication skills (Konia and Yao 2013). These competencies are sometimes even more important and more difficult to learn than basic clinical skills. Finally, simulations may increase learners' self-confidence (Figueroa et al. 2013; Gough et al. 2012; Morgan and Cleave-Hogg 2002; Paskins and Peile 2010).

Despite the acknowledged benefits of simulation-based education, challenges and the need for pedagogical development exist. Learning with simulations can be expensive and time-consuming depending on how it is conducted (Zigmont et al. 2011a). The facilitator must also have many competencies, including sufficient content-related and pedagogical knowledge (Keskitalo 2011), thus, placing high demands for appropriate simulation instructor training. In addition, it is not quite clear how simulation-based education should be realized in practice in a pedagogically sound way (McGaghie et al. 2010), as the underlying teaching and learning processes that lead to learning are not yet known. However, the strength of learning with simulations is the ability to provide meaningful learning experiences for participants (Keskitalo 2015) and, of

course, to support their learning and professional development (Cook et al. 2011).

Simulations in Healthcare Education

Within medical and healthcare education, many concepts refer to different types of simulations. Simulation is an umbrella term, which can be perceived as anything from simple verbal role-playing to more complex simulation-based training that involves modern technologies. In the most basic sense, simulation means imitating reality. Within healthcare, this means imitating the physiology or anatomy of the human body or imitating a specific healthcare process. *Role-play* is one of the simplest forms of simulations (Gaba 2004; Nehring and Lashley 2009). While role-playing, learners may practice “stepping into someone else’s shoes”; for example, a surgeon and a nurse may change roles and experience different perspectives of the same situation. The term *simulator* refers to a specific technical device (e.g., a mannequin or a screen) that attempts to mimic reality and that enables the simulation (Rall and Dieckmann 2005). In the healthcare field, the term usually refers to *human patient simulators* (also referred to as mannequins, computer patients, mannequin-based simulators, or integrated simulators) that vary in fidelity, in other words, in their ability to simulate reality (Maran and Glavin 2003; Nehring and Lashley 2009; Ziv et al. 2000). Simulators are operated (e.g., by a simulation operator or a facilitator) with a computer, which allows participants to interact with the “patient” as they would in a real clinical environment. Other types of simulations include *part-task trainers* or *task trainers*, simulators that imitate certain body parts. Part-task trainers are usually used for learning a particular task or skill (Maran and Glavin 2003; Nehring and Lashley 2009).

A *simulation scenario* is an experience-based episode, designed around a specific healthcare problem or a task. This scenario usually involves a patient simulator, simulation room, medical equipment, and role players (Dieckmann et al. 2007b). In situ *simulations* are the most realistic

forms of simulation, in which learners may practice with their real colleagues and with real equipment in a real environment (Gaba 2004). A *computer simulation* (also referred as screen-based simulation, screen-based simulator, or computer-based system) is learning with an artificial reality that is created using a computer (Alinier 2007). In a computer simulation, individuals interact with a simulated task, environment, or human physiology through a computer interface. *Standardized patients* (also referred as simulated patients or patient actors) are real human beings who are trained to act as real patients (Alinier 2007; Gaba 2004). Standardized patients can have real experience of the disease that is being simulated.

These different types of simulations and devices are usually situated in *simulation centers* (also referred as a simulated environment, a skills laboratory, or a patient simulation center) that are recreations of real work environments (Gaba 2004). Simulation centers can be also viewed as *simulation-based learning environments* (Keskitalo 2015), because they imitate reality for learning purposes. Simulation centers usually have several simulation rooms for different purposes, for example, an operating room, intensive care unit, emergency department, or ward with different types of computer-directed patient simulators mimicking patients of different ages (i.e., adults, children, and infants). There is usually also a separate room (the so-called control room) for the simulation operator and facilitators, as well as a quiet space for the debriefing.

Simulations can also be realized through *virtual realities* or *virtual worlds*. With virtual reality or a virtual reality simulator, the aim is to present a patient or an environment to a user using two- or three-dimensional (3D) virtual objects. Virtual realities are used especially in surgical training to practice procedural skills (Issenberg et al. 2001; Kneebone 2003). Virtual worlds or multi-user virtual environments are 3D shared places, where thousands of participants can simultaneously collaborate with each other via avatars in a noncompetitive manner.

However, as Gaba (2004) pointed out, a simulation is more of a technique than a

technology to replace or amplify real experiences (p. 2). Therefore, the most important factor for successful simulation-based learning is proper pedagogical use of such environments. In the following sections, the theoretical premises and pedagogical principles of simulation-based healthcare education are presented.

Theoretical Premises of Learning with Simulations in Healthcare

The idea of simulation-based learning is rooted in the ideas of andragogy (Knowles et al. 1998; Wang 2011), Kolb's experiential learning (Fanning et al. 2013; Kolb 1984), sociocultural theory (Sadideen and Kneebone 2012; Vygotsky 1978), as well as research on expertise and deliberate practice (Eriksson and Charness 1994; Wang 2011). Recently, the sociomaterial perspective has emerged as a way to understand the learning process within simulation-based learning environments (Fenwick and Dahlgren 2015). These theoretical perspectives underlying simulation-based learning are presented in more detail.

Andragogy (Knowles et al. 1998) can be considered an underlying theory of learning with simulation, focusing on educating adult learners who in this context are healthcare or medical students or professionals already working in the field (Fanning and Gaba 2007; Wang 2011; Zigmont et al. 2011a). The learners' age sets certain prerequisites for pedagogy because, according to Knowles et al. (1998), adult learners differ considerably from children in terms of age, maturity, and life experiences. Previous studies revealed that adult learners tend to be independent and self-directed and feel responsible for their own learning. They are usually internally motivated and value things that are directly applicable and beneficial (Clapper 2010; Wang 2011; Zigmont et al. 2011a). According to Keskitalo (2012), adult learners also have higher expectations for simulation-based education than younger learners do. Therefore, simulation-based education should be timely, convenient, and accessible but perhaps most importantly, learner-centered.

Learning in general (Mann 2011) and with simulations (Dieckmann et al. 2007a; Pasquale 2013) is social and collaborative. Learners interact with each other and with their sociocultural environment to solve a patient case. Therefore, the sociocultural theory of learning (Berragan 2011; Keskitalo 2015; Keskitalo et al. 2014; Paige and Daley 2009; Perkins 2007; Sadideen and Kneebone 2012) and recently, sociomaterial perspectives have been applied to understand simulation-based learning as a social practice (Fenwick and Dahlgren 2015; Nyström et al. 2016). These viewpoints consider learning (Lave and Wenger 1991; Vygotsky 1978), as well as professional practice (Fenwick and Dahlgren 2015; Nyström et al. 2016), as something more than individual processes, and success or failure cannot be regarded as completely dependent on individual performance alone. On the contrary, learning and performance are in constant interplay between individuals and their wider sociocultural context (Lave and Wenger 1991; Nyström et al. 2016; Vygotsky 1978), which is messy and dynamically evolving and where the boundaries of groups and organizations are blurry (Fenwick and Dahlgren 2015). This certainly challenges the interaction and is worthy of further examination.

Kolb's (1984) experiential learning theory is the first pedagogical model implemented in simulation-based healthcare education (Anderson et al. 2008; Fanning et al. 2013; Wang 2011; Zigmont et al. 2011a). Kolb's (1984) learning cycle involves four phases: (1) concrete experience, (2) reflective observation, (3) abstract conceptualization, and (4) active experimentation. Experiences (in this case, simulation) are triggers for learning. During simulation-based learning, an adult learner participates in the simulation, reflects on his or her experience of the simulation during the debriefing, and thereafter, transforms the experiences into knowledge that is usable in a new simulation and ultimately, in future healthcare practice (see Fanning et al. 2013).

Vygotsky's (1978) sociocultural theory and the theory of deliberate practice (Anderson et al. 2008; Ericsson and Charness 1994) have also yielded practical instructional principles

for simulation-based healthcare education. Vygotsky's (1978) zone of proximal development (ZPD) has been adopted in healthcare education as well (Kneebone 2005; Sadideen and Kneebone 2012; Stocker et al. 2014). The ZPD is the area between the actual and potential levels of development. The potential level of development is achievable by more capable peers or a facilitator, whereas the actual level of development can be reached by the learner on his or her own. Each learner also has his or her individual ZPD. Thus, teaching should be based on the competencies that are developing, not the skills and knowledge that the learner already has (Vygotsky 1978). Through a simulation, learners can be exposed to deliberate practice that is required to develop expertise (Anderson et al. 2008; Causer et al. 2014; Issenberg and McGaghie 2002; Konia and Yao 2013; Udani et al. 2014; Wang 2011). Generally, deliberate practice refers to individualized training activities that aim at improving the current performance level with repetition and refinement to reach an expert level (McGaghie et al. 2009). To put these instructional principles together, in simulation-based education, new competencies are learned during collaborative problem-solving tasks with the help of expert facilitators or more capable peers. The facilitator's main task is to diagnose the level at which an individual learner is in his or her knowledge or skills (the ZPD) and to design learning tasks, as well as provide specific, informative, and gradually fading support, as proposed by deliberate practice theory.

Meaningful Learning with Simulation in Healthcare

One of the most recent additions to the field is the pedagogical model for simulation-based healthcare education (Keskitalo 2015); see Fig. 1. This model was developed for simulation-based education by synthesizing existing theoretical knowledge and by conducting empirical studies in the field of healthcare.

The characteristics of meaningful learning form the core theoretical component of the pedagogical model (the 14 characteristics of

meaningful learning situated at the center of the model). The concept of meaningful learning was invented by Ausubel (1968) and later used in various contexts to design, implement, and evaluate education (Jonassen 1995; Keskitalo et al. 2011; Löfström and Nevgi 2007; Ruokamo and Pohjolainen 2000). According to Ausubel et al. (1978), meaningful learning is a process in which new information is assimilated with what the learner already knows during the learning process when the learner engages in the meaningful learning task and materials. Jonassen (1995) developed Ausubel's ideas further, and for him, meaningful learning was active, constructive, collaborative, intentional, conversational, contextualized, and reflective.

Meaningful simulation-based healthcare education should emphasize 14 qualities of meaningful learning (Keskitalo 2015): experiential, experimental, emotional, socio-constructivist, collaborative, active, responsible, reflective, critical, competence-based, contextual, goal-oriented, self-directed, and individual. With these qualities in mind, the facilitator can plan, implement, and evaluate the entire instructional process in order to enhance the quality of the learning experience and to develop even more innovative pedagogical practices. These 14 characteristics of meaningful simulation-based learning are presented below.

Experiential

Previous experiences guide our behavior and learning (Carlson et al. 2010). In addition, during simulation-based education, adult learners use their previous experiences as a starting point and a resource for learning (Kolb 1984; Zigmont et al. 2011a). Therefore, it is important to activate these previous experiences and apply them but also to reflect and reconsider harmful mental models (which may lead to ineffective procedures) through guided self-reflection during the debriefing (Dieckmann et al. 2007b; Wang 2011; Zigmont et al. 2011b).

Experimental

Previous experiences guide our learning, but learning with simulations is also an opportunity to provide new experiences for learners and

Learning with Simulations in Healthcare, Fig. 1 Pedagogical model for simulation-based healthcare education (Keskitalo 2015)

expose them to deliberate practice. Learners have an opportunity to experiment with new tools, devices, situations, roles, theories, etc., before entering the healthcare practice, or professionals can maintain their expertise, or a simulation can be used as a method for testing newly designed devices or processes (Cleave-Hogg and Morgan 2002; Gaba 2004). The simulation facilitator provides the sandbox for learners to experiment widely and at the same time, actively encourages and supports learners.

Emotional

Emotions are intertwined with learning in many ways (Damasio 2001; DeMaria et al. 2010;

Immordino-Yang and Faeth 2010; Schuzt and DeCuir 2002), and simulation-based learning is sometimes purposefully designed to generate emotional experiences in learners. The environment, scenarios, and materials are designed to evoke emotional reactions (DeMaria et al. 2010). The facilitator's role is to set a safe and confidential scene for learning during the beginning of the learning process, as well as take these emotional responses into account afterward.

Socio-constructivist

The aim of simulation-based learning is for learners to participate in the enquiry process and gradually accumulate knowledge about the

patient's condition from their previous knowledge, their peers, the patient's file, and medical investigations, as well as other sources, in order to deliver the correct treatment (Alinier 2011) and to co-construct new knowledge. As a result of this problem-solving process, learners accommodate and co-construct new knowledge based on their previous knowledge and experiences during the collaborative learning process (Dieckmann et al. 2007b; Dolmans et al. 2005; Jonassen 1995; Keskitalo 2012). The environment, tasks, and materials are used to support students' knowledge co-construction; for example, the facilitator creates cases that are based on learners' previous experiences and that require collaboration. The facilitator's main role, however, is to guide learners' collaboration and knowledge co-construction.

Collaborative

Simulation-based learning is designed to be a collaborative undertaking. From the beginning of the learning process, learners participate in the interaction, bringing their knowledge, understanding, experiences, and skills to the joint activity and discussion. The learning goal can be to practice crisis resource management which requires practicing leadership, communication, negotiation, problem-solving, and decision-making skills (Fanning et al. 2013). The facilitator's main role is to facilitate this collaboration and knowledge construction.

Active

The core idea is that learners participate actively during simulation-based learning. Consequently, the facilitator guides rather than lectures (Fanning and Gaba 2007; Issenberg et al. 2005; Jonassen 1995; Keskitalo 2011). The environment, materials, and pre-assignments are designed so that they require learner activity. The facilitator's main role is to plan appropriate cases and encourage learners to take an active role during the whole learning process (Alinier 2011).

Responsible

Adult learners are mature and thus, are responsible for their own learning. Teaching does not lead directly to learning (Kansanen et al. 2000);

instead, teaching is necessary for learners to actively co-construct their own understanding.

Reflective

Reflection on the learning process is often considered the most critical phase of simulation-based learning as it is the place for learners to be able to review their own learning (Alinier 2011; Cook et al. 2011; Dreifuerst 2012; Issenberg et al. 2005). Reflection involves reflecting on one's own learning, learning strategies, knowledge, skills, attitudes, and the learning environment (Fanning and Gaba 2007; Issenberg et al. 2005; Jonassen 1995; Rudolph et al. 2008) but also receiving and giving feedback (Jonassen 1995). The learning environment may include elements that support the learners' reflection (e.g., a video camera, TV, peaceful and pleasant room, safe atmosphere, competent instructor, etc.). In addition, assignments (e.g., a learning diary) can support the reflection. The facilitator supports the students' reflection by asking questions, specifying, elaborating, guiding, etc., that is, by being a "cognitive detective" (Rudolph et al. 2007).

Critical

Being critical is interrelated with the reflective feature of meaningful learning. Being critical in a debriefing is especially important in the field of healthcare where errors can lead to medical mistakes and endanger patient safety in the real clinical environment (Rudolph et al. 2006). Being critical means conducting a debriefing with good judgment as proposed by Rudolph et al. (2006). The facilitator not only critiques but also makes his or her expert view of the situation visible for learners and uses that view as the basis for exploring the learners' sense-making process. Thus, the facilitator's own reasoning becomes part of the debriefing and helps the participants form their own expertise.

Competence-Based

The learning objectives of simulation-based healthcare education should be based on the skills and knowledge needed in real working life (Anema 2010; Harden et al. 1999). This means that content is simulated through real-life cases (Dolmans et al. 2005) and the environment

includes authentic tools and devices (Alinier 2011). An experienced facilitator plans appropriate and sufficiently authentic scenarios and formulates the learning objectives collaboratively with the learners, if possible.

Contextual

Information is best learned when it is taught and practiced in a context that resembles real life (Bransford et al. 1999). The real-life context also enhances the transfer of learning. For example, the benefits of an in situ simulation are that it helped detect pitfalls in the actual work environment and helps in development of the working environment. The contextual aspect of meaningful learning can be supported by planning and designing real-life cases and environments. In addition to full-scale simulations, computer-based simulations, videos, Internet links, and worked examples can be used to support learning (Alinier 2011; Dolmans et al. 2005; Jonassen 1995; Keskitalo 2011, 2012; Löfström and Nevgi 2007; Merriënboer and Sweller 2010; Ruokamo and Pohjolainen 2000).

Goal-Oriented

Goals direct our thoughts, behavior, and strategies; thus, setting clear goals should be encouraged (Dieckmann 2009; Schuzt and DeCuir 2002). This entails adducing the general learning objectives, as well as encouraging learners to set their own learning goals (Dolmans et al. 2005; Jonassen 1995; Keskitalo 2012; Keskitalo et al. 2011, 2014; Schuzt and DeCuir 2002). For this task to be complete, the facilitator is also responsible for diagnosing learners' needs.

Self-Directed

Simulation-based learning is about educating adult learners who are self-directed and intrinsically motivated (Fanning and Gaba 2007). This means they set up individual learning goals and follow up on those goals during the learning process (Brockett and Hiemstra 1991). The facilitator maintains these learners' activities by supporting, guiding, and giving feedback. In simulation-based learning environments, for example, video recordings, debriefings, learning

diaries, observational ratings, tests, etc., can be used to evaluate learning.

Individual

Learning is different for each individual (De Corte 1995); therefore, individual differences should be considered whenever possible (Alinier 2011; Zigmont et al. 2011a). Individualized learning was also recommended by the Carnegie Foundation for Teaching and Learning of Medicine (Irby et al. 2010). The facilitator's task is to take into account individual differences, diagnose individuals' development level, and provide individual guidance and feedback (McGaghie et al. 2010; Keskitalo et al. 2014; Ruokamo and Pohjolainen 2000). The learning environment, tasks, and materials should also support individual learning styles, and the environment can be changed to meet various needs. The facilitator familiarizes himself or herself with the students and gives individual feedback and support.

Phases of the Pedagogical Model

The pedagogical model provides an example of *how* learning with simulations in healthcare can be scripted. The model includes six distinct phases: Pre-activities, Introduction, Simulator and Scenario Briefing, Scenarios, Debriefing, and Post-activities. The characteristics of meaningful simulation-based learning can be realized through these phases. Next, these phases are presented in more detail.

Pre-activities

There are specific tasks for facilitators and learners during the pre-activities phase of simulation-based learning, that is, before the actual face-to-face interaction. Learners' responsibility in this phase is to get acquainted with the theoretical content knowledge. This can be done through pre-assignments, trigger videos, readings, lectures, etc. Learning with simulation demands much work from the facilitators before it even starts. The facilitator's preparatory tasks include considering the target group and their learning needs, designing the learning objectives, and

preparing the learning material, assignments, case scenarios, and environment, among other things. According to Alinier (2011), more realistic scenarios require more time to prepare. The more experienced the learners are, the more realistic the scenario should be.

Introduction: Activating Previous Knowledge and Setting the Ground

The actual face-to-face phase starts with an introduction, the most important goal of which is to prepare the learners for the learning process and set a safe scene for learning (Arthur et al. 2013; Clapper 2010; Rudolph et al. 2008). In the beginning, participants get to know each other, and a facilitator explains the course topic and its objectives (Zigmont et al. 2011a). In addition, activating learners' previous knowledge and experiences, as well as discussion of important or otherwise difficult concepts, is important for the formation of new knowledge (Dolmans et al. 2005; Zigmont et al. 2011a). In conclusion, the purpose of the second phase is to set the ground rules and establish a safe and supportive environment for learning.

Simulator and Scenario Briefing: Familiarization

During this phase, learners get to know the physical environment and the case scenario on a general level. In addition, the simulation-based learning environment with all the technology the participants will be required to use is introduced. This phase should also involve hands-on exercises in order for learners to get acquainted with the simulator and other technological devices (Dieckmann 2009). By the end of this phase, the learners need to feel comfortable with the learning environment so they can practice effectively in the next phase.

Scenarios: Guiding and Participating

The scenarios phase is the heart of the simulation-based education. Without the case scenario, there is no learning with a simulation. During this phase, learners participate actively in the simulation and treat a patient, while the facilitator stays in the background and closely monitors the

learners' actions. In this phase, the crucial question is whether to interrupt the exercise if it is going in the wrong direction. Some suggest that the simulation can be interrupted so that learners may still achieve their learning goals (Dieckmann 2009), but others have stated that interrupting the simulation spoils the simulation realism (Fanning and Gaba 2007; Franklin et al. 2013). Based on the study by Garrett et al. (2011), learners prefer seeing the consequences of their actions for the patient's condition. This may also enhance student learning, as shown by Goldberg et al. (2015).

Debriefing: Facilitating and Reflecting

Debriefing is commonly regarded as the most important phase of learning with simulation (Fanning and Gaba 2007; Motola et al. 2013; Wang 2011) because that is when learners can review and reflect on their learning and identify any knowledge gaps. During the debriefing process, participants are responsible for reviewing and reflecting on the entire learning process, as well as identifying their knowledge gaps and forming new learning objectives, whereas the facilitator's role is to be a "cognitive detective" (Rudolph et al. 2008, p. 1011). As Pasquale (2013) stated, reflection is thinking about thinking, but in learning with simulation, it is also thinking about doing. In this phase, the facilitator's role is to encourage students to analyze the entire experience in order to enhance their learning and future practice by asking open-ended questions (Fanning and Gaba 2007; Keskitalo et al. 2014; Rudolph et al. 2007) and actively listening (Ahmed et al. 2012; Zigmont et al. 2011b). Specific individualized feedback and emotional support are also regarded as important by learners (Keskitalo 2011; Keskitalo et al. 2014; Walton et al. 2011) and facilitators (Ahmed et al. 2012).

Previous studies have proposed different models for conducting the debriefing phase (Dreifuerst 2012; Dufrene and Young 2014; Fanning and Gaba 2007; Nyström et al. 2016; Rudolph et al. 2007; Steinwachs 1992; Zigmont et al. 2011b), although there is currently no clear evidence that one method is better than another (Dufrene and Young 2014). Steinwachs' (1992)

model is a very commonly used approach (see Ahmed et al. 2012; Gardner 2013; Konia and Yao 2013; Nyström et al. 2016; Rudolph et al. 2008; Zigmont et al. 2011b). It includes three phases: the description phase (what happened, first impressions, and feelings), the analysis phase (exploration of the reasons for learners' decisions and actions), and the application phase (the take-home message and future learning goals). However, research on debriefing from the sociomaterial perspective revealed that this type of scripted learning discussion does not support learners' initiatives (Fenwick and Dahlgren 2015) and it is a teacher-centered approach to learning.

Post-activities

The final phase of learning with simulation is the post-activities phase that is often under-examined in research, although this phase is important for continuous development of learners' expertise and the development of simulation-based education (Boese et al. 2013). For learners, this phase includes application of knowledge and skills in a new scenario or in real life (see Kolb 1984; Merrill 2002). For the facilitator, post-activities mean evaluating learners' learning processes and developing the education further. Wang (2011) proposed two frameworks that can be used to that end, Kirkpatrick's (1998) and Kneebone's (2005). However, the characteristics of meaningful simulation-based learning can be used to evaluate simulation-based education. For example, the facilitator and learners may evaluate how well the individual aspect of learning was realized. If this aspect is not realized well, they may think of ways to realize it better in the future.

Conclusions

Previous studies have shown that simulation-based learning is beneficial, but future studies should concentrate on the underlying teaching and learning processes that have led to these successful outcomes (Garden et al. 2015). According to Cook and others (Cook et al. 2011), we do not know enough about when, how, and to what the simulation-based learning environment should be

applied. In the other words, it is known that learning with simulation works but how exactly remains unknown. This knowledge would help us to optimize the use of simulations in healthcare education.

Lifelong Learning for Working People

John Field

Faculty of Social Science, University of Stirling, Stirling, UK

The idea and practices of lifelong learning are now commonplace across much of the world, largely as a result of policy responses to accelerating economic change (Field 2006; Tuijnman and Boström 2002; Zapp and Dahmen 2017). The challenges to which lifelong learning is said to propose a solution, though, are multiple and complex. Across the globe, new technologies from digitization to robotics have come together with globalization off the economy and the consequent reconfiguration of work to transform the labor market for new entrants while placing new demands on older workers to adapt to changing career prospects. In many countries, particularly the established economies of North America, Asia, Europe, and Australasia, these trends are further impacted by a general shift away from manufacturing toward service employment, as well as by important social changes, including population aging and growing diversity arising from migration. At the same time changing social values have led to new expectations around the transition from education to work, as well as greater equality of access to working life and its rewards, along with wider interest in the quality of working life and its relationship to the rest of our lives.

Whether it is realistic to see education and training as the answer to these challenges is debateable. The entry explores the ways in which these tendencies have affected the demand for and supply of skilled labor, with considerable implications for governments, employers, and

workers. The idea of lifelong learning can be understood as a response to these conditions, involving as it does the belief that workers of all ages and across sectors will be required to continue updating their skills and qualifications throughout their working lives. The entry will review policy responses by governments and international government bodies such as the OECD; it will also attempt to summarize the main trends in employer responses, though these are inevitably diverse and uneven. It will also examine the available evidence on trends in worker participation in continuing education and training. Finally, it will review the ways in which information technology is being adopted as a solution to the challenges of continuous workforce development and cautiously assess the impact of these developments, including recent initiatives in open education.

The Inexorable Rise of Lifelong Learning

The OECD recently commented that: “Skills have become the global currency of the 21st century” (OECD 2012, 3). Such language is familiar, and the case for investing in skills is widely accepted – so much so that there might be a risk of taking it for granted. In recent years, governments have responded to the challenges of the global knowledge economy by paying increasing attention to skills and education, not only among young people still in school but also among the existing workforce. While one possible response to population aging in the West is to attract skilled migrants, this is often politically controversial, and anyway migrants also grow older over time. And one country’s immigration is another country’s emigration, leading to a loss of skilled workers with subsequent negative effects on productivity and competitiveness (Docquier et al. 2014). So for many governments, as well as for many enterprises, increasing the adaptability, productivity, and employability of workers and improving their capacity for lifelong learning present a pressing challenge.

The European Commission, one of a number of international and national government bodies that

has recently embraced the idea of lifelong learning, defines it as “all learning activity undertaken throughout life, with the aim of improving knowledge, skills and competences within a personal, civic, social and/or employment-related perspective” (Commission of the European Communities 2001, 9). What was significant here was not simply the idea of developing policies for learning at all stages of the life course but also the idea that learning took place in all spheres of life and not just in formal educational settings. Like most other government bodies, the Commission emphasized the breadth of the term, which they understand as encompassing “the full range of formal, non-formal and informal learning activity” (Commission of the European Communities 2001, 9).

The breadth of this definition poses challenges to policy-makers, as it potentially addresses any form of learning – however trivial, wherever undertaken, and whether the learner is conscious of it or not. But it was clearly intended to shift attention away from an input model which focused on planned instruction in formal settings, toward an output model which focused on the learner and his or her development. It was therefore consistent with the slightly earlier shift in those concerned with promoting learning at work, who increasingly described themselves as human resource developers or coaches and less and less as trainers. And more broadly, the language of skills and training is itself changing as part of this preoccupation with learning throughout and across the life course. Simply to take one particularly striking example, the organization founded in 1943 the American Society of Training Directors, which changed its title in 1964 to the American Society for Training and Development, renamed – and rebranded – itself in 2014 as the Association for Talent Development, or ATD (Torraco 2016).

These developments have expanded the contexts and concepts of work-related learning beyond the relatively narrow confines of the classroom or training center. Unsurprisingly, popular understandings of training tend to be far more narrow and specific than the broad definitions that are used by researchers and policy-makers, and it follows that training levels go underreported in many

surveys (Campanelli and Channell 1994). More recent evidence from the UK Employer Skills Survey suggests that many managers do not recognize coaching or mentoring as forms of training, but are likely to understand training as involving a relatively simple transfer and acquisition of knowledge and skills between expert and novice (Winterbotham et al. 2011, 11–14). Rather than an “acquisition” mode of learning, recent theories of learning have tended to understand learning in terms of “participation,” “construction,” or “co-construction” (Sfard 1998; Engeström 2001; Illeris 2018).

The notion of skill at first appears relatively straightforward, at least by comparison with the idea of training. But again it has connotations that can be loaded down with cultural baggage, and these too have evolved and changed as a result of new perspectives. In general, the idea of skills has acquired a strongly positive gloss, and it has sometimes displaced older terms like adult training or education. For example, the Organisation for Economic Co-operation and Development has branded its international study of workers’ basic competences as the “adult skills survey” (OECD 2013). In Britain, the word was for long associated with status hierarchies inside the labor force; a “skilled worker” (or, often, a “skilled man”) was someone who had completed a particular type of apprenticeship and whose status and autonomy was often fiercely protected by trade unions. More recently, the term has been enlarged in response to underlying changes in the economy, which have resulted in the use of the term to encompass attributes such as communication, teamwork, problem-solving, creativity, and other so-called generic skills or soft skills.

In practice, though, much workforce training is not really concerned with learning new skills – at least, not in the sense in which most people use the word. Quite a high volume of training is undertaken in order to comply with legislative requirements or regulatory frameworks, which demand that people train to a specified standard regardless of whether they already have this knowledge or not. In Britain, for example, 71% of employers reported that they had provided health and safety training in 2011 (Davies et al. 2012, 113), almost

all of which was designed to underpin compliance with legislation.

Widespread adoption of the language and idea of lifelong learning has involved a new verbal emphasis. This has affected perceptions of those involved professionally in the field, with many people now referring more to supporting learning rather than providing training and teaching. Illeris dates the origins of this change back to the 1970s, when influential theorists such as Argyris and Schön helped to refocus attention on acquisition rather than instruction; by around 1990, he suggests that the language of learning increasingly took on a social dimension, evident not only in concepts of situated learning or activity theory but also in more popular notions of the learning organization, learning city, or learning region (Illeris 2018). Greatly influenced by the seminal and popularly written work of Jean Lave and Etienne Wenger on situated learning, constructivist theories emphasize the ways in which workers produce and share their skills and knowledge through participation in the workplace (Lave and Wenger 2001). In this model, rather than trainers and trainees, learning occurs when a novice participant is accompanied and guided by more experienced workers from peripheral to full participation.

Yet although learning is increasingly seen understood by many practitioners and researchers as an intrinsically social practice, policy perspectives often focus on the role of individuals. I have argued elsewhere that the discursive shift toward lifelong learning is associated with a wider rebalancing of responsibilities for learning, with a reduced role for the state and increases in the responsibility of individuals and employers to invest in and coordinate upskilling and talent development (Field 2006).

These definitional and terminological issues help us understand why it can sometimes be challenging to agree on how skills and training should be measured. At enterprise level, Kirkpatrick’s model of training evaluation has dominated the field since its first publication in the 1960s (Kirkpatrick 1967). This model proposed four “levels” of criteria for evaluating training: reactions, or how people feel about the training they have received; learning, or what they know as a

result of the training; behavior, or what they can now do; and results, understood as the influence that the new skills and knowledge have on the organization's performance. While this model has been widely criticized in the academic literature as oversimplifying training, and presenting the outcomes as a linear sequence organized in an unproblematic hierarchy, its clarity and applicability continue to appeal to professionals in the field (Yardley and Dornan 2012). Surveys of current practice tend to confirm the view that few organizations have moved toward more creative ways of evaluating and measuring training. In countries such as the UK, for example, the most frequently used tools are post-course evaluations (commonly known as "happy sheets"), and individual testimonies, followed by attempts to measure outcomes, and finally by assessments of the impact on key business objectives (CIPD 2011, 5). Similarly, most US training managers use only the low-effort levels of evaluation, such as measuring participant reactions and assessing their learning, with relatively few attempting to estimate the results in organizational terms or calculate the return on investment (ASTD 2010, 21).

This focus on simple evaluation tools is a rational response to the difficulties of estimating the organizational return on investment from training. The first challenge is to distinguish the effects of training from all the other factors in the workplace that might affect productivity. Very few studies have tried to separate out the impact of training from the effects of other strategic interventions, such as team membership changes, appraisal, profit sharing, or worker participation in decisions (for an exception, see Akhtar et al. 2008). The second is to discriminate between the effects of training on the worker and the influence of the worker's characteristics on skills acquisition; economists believe, for example, that employer selection decisions are biased in favor of the most capable workers, so that employers sometimes overestimate the results of training activities (Vignoles et al. 2004). Third, at company level, there is some empirical support for the intuitive belief that low-performance enterprises are less likely to train than high-performance enterprises (Dearden et al. 2006; Zwick 2006). Finally, there

is the question of time scale: in many cases, a considerable time period is needed to monitor the effects of training, yet company goals are often measured over the short term; even if managers are willing to take the long view, the prospects of other factors intervening are increased.

Economics, particularly in the form of human capital theory, has made a particular contribution to the measurement debate. Essentially, this theory states that skills and knowledge represent a form of capital, part of which is the result of deliberate investment. Initially the idea was developed by Theodore Schultz as a way of exploring the economic value of education, particularly in relation to economic growth (Schultz 1961). Subsequently the theory was developed by Gary Becker, who extended the analysis to include continuing training as well as other investments in skills, as well as developing a sophisticated cost-benefit analysis as a way of explaining educational decisions. Becker distinguished, for example, between general training, which he claimed was mainly of benefit to the worker as it raised their future wages by improving their attractiveness to other employers, and firm-specific training, which he saw as more likely to benefit the employer, by raising productivity without raising wages (Becker 1993, 31–51). For Becker, this distinction meant that employers would pay for specific training, but normally general training would be paid for by the worker. He also argued that employers would invest more in those workers where they could expect the greatest return, one side effect of which was lower investment in women workers who typically spent less time in the labor force than men (Becker 1993, 88).

Human capital theory has been widely criticized for what some see as its excessive individualism and its reliance on rational choice models of decision-making (Field 2003, 21–22; Tan 2014). By treating skill as an attribute of the individual worker and explaining all decisions as the result of rational calculations of individual rates of return, it is argued that human capital theory is deeply flawed conceptually and unable to deal with the socially embedded nature of decision-making. The theory has also been attacked

for its use of oversimplified tools of measurement, such as years of schooling or the gaining of formal qualifications, which are unrelated to actual skills and abilities. Finally, it tends to present a direct linear model of investment and return, yet empirically much research on returns to education have suggested that the relationship may be multilinear and iterative (these concerns are rehearsed in Field et al. (2000, 249–251). Nevertheless, the theory certainly has some explanatory power and has been widely supplemented by forms of cost-benefit analysis to inform decisions about the funding of training and development activities.

Securing Knowledge and Skills Development

Skills and their development command almost universal support. Policy-makers proclaim that upskilling will lead to greater competitiveness, inclusion, and cohesion, while employers and trade unions alike proclaim their support for training and development. In fact, it is virtually impossible to find anyone who opposes upskilling. In part, this arises from simple demographics. The US Census Bureau expects more than 20% of residents by 2030 to be aged 65 and over, compared with 13% in 2010 and 9.8% back in 1970 (US Census Bureau 2014). Other advanced nations, particularly Japan and South Korea, anticipate much more dramatic rises in the proportion of over 65s (Bengtsson and Scott 2013). Conversely, the share of those of traditional working age in the population is falling, and governments, employers, and individuals increasingly accept that working life will, in many cases, be longer than most people previously expected. The adaptability and employability of this aging workforce, and therefore the productivity and competitiveness of enterprises and nations, depends in large part on the extent to which it can continue to develop and apply new skills and abilities.

Governments, individuals, and employers have an interest in developing strategies for upskilling the workforce and developing potential. Yet despite the policy consensus in favor of upskilling, and widespread evidence that it has

both private and social benefits, there are controversies over the best ways of promoting continuing training. Particularly contested areas include the funding of training, and in particular, the question of who should pay for what? To what extent should the state intervene, whether as direct provider of learning and development or as an enabler and incentivizer? Moreover, as well as the financing of skill formation, Busemeyer and Trampusch identify three other “neuralgic points” of conflict: the tension between enterprise autonomy and state involvement (who controls what), the balance between school and firm in initial vocational education and training, and the relationship between the VET system and the wider educational system (Busemeyer and Trampusch 2012b, 16). In addition, when it comes to continuing skills development for the adult workforce, there is the question of what involvement public education bodies such as universities and colleges should have and on what basis.

Moreover, much policy focus has concentrated, perhaps understandably, on areas of identifiable growth. In occupational terms, this has often led policy-makers to present summaries of labor market trends that show an increase in high-skill employment and project a continued decline of low-skilled jobs. However, as the OECD has noted, while there is indeed growth in some high-skill occupations, such as managers and scientists, the loss of traditional male unskilled jobs has been largely balanced by a growth of low-paid service jobs, which happen often to be performed by women and migrant workers; it is the middle-skill jobs that tend to experience relative declines, whether in services or in manufacturing, partly because these occupations can be transformed through computerization or even automation (OECD 2010, 24–25).

From a policy perspective, the pace of change and the degree of uncertainty in the labor market imply a focus on providing workers with robust skills and the capacity to develop new competences. This requires strong basic skills (literacy, numeracy, and information technology) through initial education or through compensatory measures for those who did not develop these basic skills earlier in life. Increasingly, governments are also seeking ways of

developing what are sometimes called generic or key skills or transversal competences, such as problem-solving, teamworking, communications, and, perhaps above all, “learning to learn” (Commission of the European Communities 2010, 10). In developing its policies for skills and employment, the European Commission continues to call for “comprehensive lifelong learning” as a way of achieving the balance of flexible and secure employment that it describes as “flexicurity” (Commission of the European Communities 2010, 5–6).

There is also an emerging debate over the balance between supply and demand. Particularly in Britain, it has been argued that public policy focuses almost exclusively on the supply of skill, largely ignoring other factors involved in determining productivity, such as investment strategies and work organization (Keep et al. 2006). In some countries, though, policy attention has recently widened to encompass the utilization of skills as well as their formation. This development is usually dated back to a 2001 report, in which the OECD argued that it was not enough simply to invest in improved skills; if new skills were to contribute to improved performance, it proposed that work practices must also change. This was not, the OECD stated, simply a matter of introducing new techniques and tools; it also meant “a reorganization of work,” with particular attention to such factors as employee involvement, flexible working, and flatter hierarchies that favored high-performance working and technological innovation (OECD 2001, 15–16). OECD has described these features as characteristics of the “learning organization,” accompanied by human resource practices that are aligned with the goal of continuous learning and smooth internal communications (OECD 2010, 73–74).

So far, the policy implications of a focus on skills utilization are not entirely clear. Nevertheless, strategies that seek to make the best use of existing skills, as well as developing new ones, have considerable potential if they can be operationalized in concrete ways. They are likely to be particularly important for enterprises that employ significant numbers of such groups as older workers, who are likely to remain active in the labor market where their existing knowledge

and competences are recognized (Canning 2011; OECD 2012, 64–72). While there are some individual examples of improvement in skills utilization at enterprise level, sometimes involving support from trade unions as well as managers, this remains a work in progress (OECD 2017).

Developing Skills in Practice

Investing in skills can take a variety of forms. Particularly with the advent of interest in lifelong learning, human resource managers have started to explore a broad range of ways of developing skills. In part, this is also a response to the changing nature of work, as well as to the increasing potential of new technologies as ways of communicating information and ideas. A number of studies suggest that while face-to-face delivery remains the norm, it is increasingly being challenged by newer forms of training (CEDEFOP 2010, 65). These include blended learning, coaching, and mentoring, all of which appear to be particularly prominent in the UK but are being widely adopted across the European Union (Observatoire CEGOS 2012, 3). More radical forms of innovative learning, such as job rotation and learning circles, are used relatively rarely; however, job rotation is an important additional form of training in some countries, particularly Sweden and Austria, while learning circles are similarly important in Austria and Denmark (CEDEFOP 2010, 66). Finally, the adoption of digitized learning resources, and their often instant availability through mobile devices, is increasingly influencing approaches to supporting lifelong learning at work and in the community.

Estimates of the overall volume of skill development are plentiful, but often difficult to interpret. The 2010 European Continuing Vocational Training Survey found that participation rates ranged from a low of 11% of the workforce in Latvia to a high of 59% in the Czech Republic, with an average of 38% (up from 33% in 2005); the proportion of enterprises providing training ranged from 85% in Denmark down to 21% in Greece (CEDEFOP 2015, 66–69). Trend data suggest that adult participation in training is

rising. According to one global survey, the proportion of employers training and developing existing employees to fill open positions doubled between 2006 and 2016 from one in five to over half (Manpower 2017). Of course, these are overall figures. In practice, participation in training varies enormously across the workforce.

Training provision varies by sector, with the highest participation rates found in sectors involving person-to-person services. In the UK, for example, the Employer Skills Survey has shown that training levels are much higher than average in health, social care, and education, followed closely by public administration and financial services; it is notably below average in agriculture, manufacturing, transport, and communications (Davies et al. 2012, 110). European data also suggest that formalized arrangements for training are most common in the finance sector, followed by the gas, water, and electricity industries (CEDEFOP 2015).

Perhaps unsurprisingly, participation is higher in firms where collective bargaining covers training than in those where there are no joint agreements (CEDEFOP 2010, 55–57). Some governments actively involve trade unions in promoting levels of training and ensuring its relevance. In the UK, for example, the government sought to promote investment in training by encouraging the appointment from 2000 of workplace union learning representatives (ULR); by 2009, over 10,000 union members had served for at least a period as a ULR, most of whom had never held a union office previously (Saundry et al. 2010, 12). The UK Government also supports trade union provision of education and training through its Union Learning Fund. Managers reported that in some cases, ULRs have also helped develop new courses, particularly in basic skills areas such as literacy, computing, and numeracy (Saundry et al. 2010).

Participation also varies by worker characteristics. Age is a major factor, with participation falling rapidly over the life course (Boateng 2009, 3). According to OECD data, older people also receive the lowest number of hours of continuing training (OECD 2011, 367). In aging societies, the retention and productive employment of older workers is a key issue for governments and

for many enterprises, as well as for older workers themselves. Encouraging greater upskilling though lifelong learning is a popular policy response, though its importance and form will vary according to the existing level of older workers' skills. In countries like the USA, where older workers perform well in skills assessments and also appear to use these skills as much as younger workers, employability rates for older workers tend to be relatively high. Even in ICT usage, survey data suggest relatively low age differentials across the US workforce (OECD 2018, 77–78).

Immigrant workers experience lower levels of training than the native born (Rosenblatt and Bilger 2011, 67). Occupational status is another factor, with participation rates rising among white collar workers and peaking among managers and professionals (Boateng 2009, 4; Rosenblatt and Bilger 2011, 68). And it varies by prior education, with particularly low participation rates in most countries among workers with no formal qualifications (Boateng 2009, 5; OECD 2011, 377). Seen from the perspective of human capital theory, the most precarious and least skilled appear to represent a poor investment. There is some empirical support for this generalization, in the form of survey evidence on the priorities of human resource and training managers in enterprises (Observatoire CEGOS 2012, 4). In general, these patterns can be found across most countries, though the inequalities are greater in some cases than others.

Gender is also a factor that affects participation, though not necessarily in a straightforward manner. Some evidence points to an under-representation of women. For example, in 18 of the 25 countries covered by the OECD, men received more hours of training than women (OECD 2011, 368). However, overall figures for the UK suggest that training provision is broadly in line with the share of women in the workforce, while female participation is slightly above that of men (Canduela et al. 2012, 47; Department for Business, Innovation and Skills 2008, 29). The same has been found for Germany, where roughly the same proportions of men and women participate in vocational training (43% against 42%); among

part-time workers in Germany, women were more likely to undergo training than men (Rosenblatt and Bilger 2011, 65–66). These patterns can be extremely difficult to interpret and evaluate, partly because of the persistence of gendered labor markets, arising from the tendency of some occupations to remain predominantly female while others remain predominantly male. There is also some evidence that some women, particularly those with caring responsibilities, tend to make different occupational choices from men, though whether this is for positive or for negative reasons remains contentious (Hakim 1996). One analysis of data from the European Social Survey, which controlled for such other factors as worker and occupational characteristics, found that all other things being equal, male workers in any given category were more likely to participate in training than their female equivalents (Dieckhoff and Steiber 2011). For some commentators, this is explicable in terms of human capital theory: employers are likely to invest less in women workers because they are less prone to stay with the firm, and therefore the return on investment will be lower; and women workers are likely to underinvest in training if they see themselves as secondary earners (Hakim 1996, 69, 121). In so far as these factors cease to characterize women workers, then the human capital argument implies that women workers will receive similar training investment to their male counterparts.

Such equity issues have a wider importance, as a number of studies show that for people of working age, access to education is largely decided or denied by their occupational position. Work-related learning accounts for much participation in adult education more generally (Boateng 2009, 3). More broadly, much of the variation in participation in learning more generally appears to be explained by transitions in the workplace (Biesta et al. 2011, 38–40). As we have seen, moreover, participating in training has a number of positive outcomes for individuals and organizations, as well as for regions and nations. In adopting lifelong learning policies from the late 1990s, a number of countries insisted that their policies would promote “lifelong learning for all,” in the belief that the new economy required a step change in

skill levels across the board and not only among a small number of key workers (Field 2006; OECD 2012). Relatively few countries have succeeded in achieving this balanced approach to skills, though in general, the open Nordic economies tend to be characterized by high overall participation and low levels of inequality. Drawing on survey data, Dieckhoff and Steiber found that although inequalities were similar in all the 25 countries studied, they appeared to be less pronounced in the Nordic nations (Dieckhoff and Steiber 2011, 151).

The question of how training is financed is both complex and vexed. There is considerable controversy over the level of investment in skills, as well as in the distribution of investment between government, workers, and employers; furthermore, levels of government support vary considerably across countries. In general, large firms tend to spend more per worker on training than smaller firms (Davies et al. 2012, 124; CEDEFOP 2015, 178–179). The average spend is also higher in financial and business services than in other sectors (CEDEFOP 2015; Davies et al. 2012, 129). Analysis of the European CVT Survey suggests an average spending by enterprises across the EU on training of 1.6% of total labor costs, ranging from a high of 2.5% in France to a low of 0.7% in Greece (CEDEFOP 2015). Spending in the United States was somewhat higher, averaging around 2.14% of payroll (ASTD 2010, 9). The contribution coming from government varies both in level and type; in Europe, types of government support at national level range from tax incentives and direct subsidies to grants to firms or individuals, with subsidies also available from the European Commission to support some types of training program within the member states.

Professionalization of training has developed unevenly in recent years. Across Europe, some 15% of enterprises have a training center, 32% have a dedicated training budget, and 42% have a named individual with overall responsibility for training. In all these cases, larger firms were more likely to have dedicated resources, and smaller firms were less likely (CEDEFOP 2010, 38–40). As for training supply, much takes place within

the private sector, which is large and fragmented, with a small number of very large providers, often providing training as one of several business services or as an addition to their main product (as in IT supply), and a very large number of small providers, including a sizeable number of sole traders who may provide training on an intermittent or part-time basis. In many countries, this disparate private sector has grown rapidly. A study conducted just before the recession in the UK noted that the number of training providers registered for value-added tax doubled between 2000 and 2008 (Simpson 2009, 10).

A number of commentators have singled out the Northern European nations as particularly successful, often attributing their effectiveness at skills formation to the arrangement of institutions that are sometimes referred to as “coordinated market economies” (Green et al. 2006). Of course, such arrangements are themselves dynamic and must adapt to changing circumstances. They are currently in a significant process of adjustment as a result not only of globalized competitive pressures and the shift away from manufacturing and primary industry but also as a result of Europeanization and changing political complexion of the governments (and electorates) involved. While these change factors are commonly acknowledged in the literature (see the essays in Busemeyer and Trampusch 2012a), it is less often recognized that these collective skill arrangements appear to be much stronger in strengthening initial vocational training than they are in promoting continuing skills development.

Trends and Prospects

Skills development is widely embraced as a way of securing future success in an uncertain economic environment. In many countries, investment in adult training and development appears to be increasing in response to widely shared challenges and opportunities. Yet although there is a strong general consensus on the value of skills, and the need to promote learning and development throughout working life, there is less

agreement on the priorities and methods to be adopted. Partly this is because there are real differences of interest at stake, in a context where different parts of any organization will have different interests and where information about the outcomes of training is often incomplete and unevenly shared. It is still common for many managers to view training as a cost, rather than as an investment; and it is also common for governments, particularly in the more liberal economies like Britain and the USA, to separate training programs for vulnerable groups (such as the unemployed) from policies for skills training in industry, which tend to view training as primarily a private concern. This is, then, a field characterized by continuing tensions and uncertainties.

Some of these arise from conflicts between current economic patterns and interests on the one hand and those that we may view as desirable to achieve sustainable growth. If policies focus on skills for high-performance organizations, which may be in the long-term public interest, then they will likely neglect those organizations that specialize in low-cost and low-quality goods and services. Yet in the actually existing economy, low-skill employment may be an important driver of growth for certain regions or nations, even if its long-term fortunes are highly vulnerable to competition from other low-cost regions. Moreover, I have already noted that much recent research into skills development tends to emphasize the importance of knowledge creation within work teams, which requires a very different approach to strategy and policy from traditional training responses (Felstead et al. 2009, 203–48). Research into informal learning in the workplace has demonstrated the significance of relationships of reciprocity and trust, which enable the sharing of ideas, techniques, and solutions to problems. Strategies and policies that foster such conditions are likely to prove extremely challenging for many managers, and also for many trainers, who will see them as involving decisions and choices that are outside their traditional expertise. Despite improvements in recent years, moreover, human resource development still has relatively low status within many organizations. The dominant management cliché, which speaks of people as

“our most important asset,” risks reinforcing a culture of cynicism unless it is supported by real substance.

A further source of tension arises from the growth and proliferation of training suppliers. The growing economic importance of learning in a global knowledge economy creates new economic opportunities for skills developers and trainers. We can see this in the rapidly expanding number of private providers in the UK (Simpson 2009). The “third sector” of voluntary and charitable organizations is also extremely active in many countries in providing training. In this ever more complex and crowded market place, quality assurance becomes a crucial issue. Among other “kitemarks,” the continuing development of specifications through the International Organization for Standardization (ISO) is a particularly important example of a wider development. Most recently, the ISO has approved basic requirements for providers of learning services in nonformal education and training, ISO 29990:2010. Its underlying aim is to enhance transparency and allow comparison on a worldwide basis of learning services. However, this too is a crowded field. Within the EU, member states and the European Commission have been working to establish a European Quality Assurance Reference Framework (EQAVET) to promote and monitor continuous improvement of national systems of vocational education and training (VET). Whether such schemes will develop any traction in such a disparate and growing area, which at present is largely unregulated outside certain specialist areas, remains at present an open question.

Skills and learning are also being transformed by the very processes of change and adaptability that they are often intended to address. This is visibly the case with new technologies, where digitization in particular has started to transform the availability and portability of learning resources, as well as widening the scope and reach of older training methods such as simulations and game-based learning. Massive open online courses are one example; an initial scoping report for the OECD suggested that they were “particularly well-suited to corporate learning and development,” partly because of their accessibility and low cost, as well as the possibilities for peer

interaction and credentialization that the technology affords; they were less good, though, at engaging less motivate learners, and their large scale made them unsuitable for personalized development (OECD 2016). Newer and more flexible forms of open education, from the adoption of open educational resources to gamification, are still in their early stages; whether they can overcome some of the limitations of MOOCs is still unclear, and at the time of writing, their use is mainly in the form of blended learning, complementing more established face-to-face forms of training and development.

Skills development for the adult workforce is one of the main levers for survival and success in a highly competitive global market place. By the same token, it must play a central role in expanding workforce participation and ensuring that all are able to make the most of their potential. It is therefore a topic of interest to policy-makers and researchers, as well as to those who lead enterprises and manage their workforce. As we have seen, there is also a substantial body of evidence that demonstrates the impact of training and skills development for individuals, which means that the subject is therefore of wider social interest to the public and the media. Sometimes, skills and training can be presented as “magic bullets” which will crack a previously unsolved problem, from racism in the police to disasters on oil rigs. Yet there is often a sense that skills and training are “unsexy” subjects that only hit the headlines when things go wrong, or when they impinge upon an issue of wider concern, such as youth unemployment. The vested interests in the current focus on initial training and education for the young are powerful forces; if we are to witness a shift toward upskilling the whole workforce at every stage of working life, as recent policy trends imply, then the degree of culture change required will be very considerable indeed.

Introduction

Literacy and technology is a contested and con- troversial field for a number of disparate reasons. There are a number of different definitions of literacy and these are often seen as perspectives

from specific domains, such as cognitive psychol- ogy or sociology or anthropology. Views in rela- tion to technology are no less contested and are often polarized in terms of technological deter- minism and technological evangelism. Various strands of contention must be understood to clearly appreciate the issues surrounding literacy and technology through the widest lens.

A Short History of Literacy and Technology

Many recognize technology in relation to the rise of digital practices, but those in the realm of media ecology would broaden the field significantly and point to technology as having a much longer his- tory, enabling those making claims for it – espe- cially in relation to literacy – to stand further back and assess its impact over millennia, rather than decades or centuries (McLuhan 1964). Three scholars who have made wide-ranging claims for the importance of the technology of the written word, and its impact on literacy and literacy’s impact on the individual and society, are Eric Havelock, Jack Goody, and Walter Ong. Their research attests that the first use for literacy can be seen in the form of accounting (seen c. 3500 BC): economic transactions recorded in cunei- form, beginning with pictographic symbols, nec- essary for an increasingly urban civilization that needed more formal forms of record keeping (Ong 1982: 85). As writing developed, as can be seen in later Sumerian and Akkadian writing, mastery became increasingly difficult and reserved for a few elites. It was with the rise of alphabetic writ- ing, perhaps firstly seen with Ugaritic and then perfected in the Greek alphabet, that writing was streamlined to enable efficient reading and writ- ing, thus expanding its uses exponentially.

One of the claims that scholars such as Have- lock et al., and more recently Marynne Wolf (2008) and Susan Greenfield (2014), assert is that literacy enables deeper thought. Ong writes “To live and to understand fully, we need not only proximity but also distance. This writing provides for consciousness as nothing else does” (1982: 81). Eric Havelock (1973) looks back to Ancient

Greece to look at the connection between literacy and thought. With the intellectual achievement that was the Greek alphabet, it might be wondered why there was no sudden democratization of literacy. But like today, it can be seen that technology moved slowly where education was concerned. Ancient Greece was still very much an oral culture, but such cultures need ways of transmitting their codes and practices, their history, and accomplishments. The poetic tradition was the means by which these significant aspects of the civilization were being transferred from generation to generation. However, for this to be the case, then extensive powers of memorization had to be utilized and memorizing such large amounts of material affected the psychological and mental processes. For the Greeks to learn their history and to pass on what their culture held dear, was to identify with the emotional and psychological state of those whose lives they were passing on; that, with the further aids of repetition, rhythm, rhyme, and other poetic devices, was the only way to ensure that such vast swathes of knowledge could be remembered. Yet Havelock believed that it was this oral culture that was a chief obstacle to rationalism and reasoned, objective analysis. He notes that this is why Plato saw the great poets as the enemy of the people “and it is easy to see why he considered this enemy so formidable; he asks of men that instead they should examine this experience and rearrange it, that they should think about what they say, instead of just saying it. And they should separate themselves from it instead of identifying with it; they themselves should become the “subject” who stands apart from the “object” and reconsiders it and analyses it and evaluates it, instead of just “imitating” it” (1973: 29). For Plato, the examined life necessitated the use of literacy; the ability to analyze, categorize, rationalize, and evaluate.

Although there are many scholars today who defend these claims for literacy, these claims are contested by others who reject this “autonomous model of literacy” and see the rise in modern digital technologies as a way to focus on the participatory, collaborative, and distributed nature of what are often now called multiliteracies or new literacies.

New Literacy Studies

Brian Street is a significant opponent of the autonomous model which he also sees as a “technology of the mind.” Street (1984) was one of the earliest scholars involved in New Literacy Studies, a tradition focusing on literacy as a set of social practices rather than on the “schooled literacy” of reading and writing. Street believes that schooled literacy is value-laden and based on an assumed set of unquestioned beliefs (especially the autonomous model of literacy) that impose a Western capitalist model on those who submit to such practices. From this perspective, the autonomous model of literacy can be seen to marginalize certain cultures and peoples and come from a culture of power and domination. This perspective challenges categories and definitions used by those in authority, such as the United Nations, which can brand others as illiterate or as failing to meet a predetermined standard. Those holding to this autonomous model are also the ones who are seen to have the power to determine education policy and literacy programs, including pedagogy and text books. Instead Street proposes an “ideological model” of literacy, recognizing literacy’s social and cultural contexts and New Literacy Studies stresses a plurality of literacies, coined as multiliteracies by the New London Group. Building on the ideological model of literacy, multiliteracies values the various (often dismissed) practices involving print literacies, practices around multimodal texts, and practices around new digital and social media.

Literacies and Technology

James Paul Gee is another stalwart of the New Literacy School and its perspectives and he has written extensively on how, if literacy is seen as a set of social practices, then the use of digital technology is simply another social practice through which literacy can be manifested and understood (Gee 2015) Recognizing Ong’s early contribution to the field of digital technology and literacy, which he believed would introduce a new form of “secondary orality,” Gee develops this

analysis, though using the more positive term “retained orality.” Gee sees this form of hybrid spoken and written language in social media, as one aspect of the “new” in new literacies and an aspect of literacy practice that enables democratization and participation. Along with this aspect that digital technologies can contribute to new literacy practices, he shows that new modalities such as images (including moving images) and sounds meld with text to increase their richness and accessibility. As opposed to literacy practices that are often the domain of school, Gee points to what he calls “affinity spaces” (2015: 118–127) where these new literacies can encourage socially constructed knowledge and enable participants to engage not only in learning about information, but learning about themselves and building their own identities. In contrast to information encountered in school, Gee and others (see Knobel and Lankshear 2007) champion the distributed nature of online learning which challenges the domination of teacher and text book authority.

The rise of digital technologies has led to online affinity spaces which can enable a range of literacy practices. Technology has enabled such learning environments which emphasize collaboration and participation. This can be seen in the research of Rebecca Ward Black and her work in the field of Fanfiction (Ward Black 2008). She points to the “authentic” writing that can be seen on fanfiction sites, where fans of particular genres of media or specific shows, write fiction based on their following. She contrasts the liberty found in this medium with writing in school: “. . . texts produced in the classroom are artefacts of a print based culture and reflect the conventions of print as well as the constraints of academic genres and writing” (2008: 130). Taking New Literacy Studies as a framework for her analysis, she recognizes the benefits of such writing spaces where there is more room for experiment. One of her research studies looked at a Chinese girl and her fanfiction over a 2-year period. She noted the collaborative form of such work, where others on the site would comment and encourage so she could learn from the “community.” This feedback and her growth from learner to expert helped what Black described as the construction of the girl’s identity

as a successful fanfiction author. Black contrasts the active learning that these sites can offer with the “spaces of enclosure” found in schools. She also emphasizes the distributive nature of affinity sites, where there is a lack of authorised roles and imposed forms of knowledge (Ward Black 2008: 125–144).

Literacy practices in these spaces are heralded as collaborative and authentic. As well as contributors to such spaces being enabled to perfect their work through the use of digital tools such as spellcheckers, multimodal frames, and online authoring software, there are other passionate producers (a term coined by Muller (2009) combining the idea of consuming and producing) as can be seen from the above research, to scaffold and support the writer’s endeavor. This social emphasis points back to Street’s focus on literacy as a social practice and encourages practitioners to recognize their literacy events through such a lens. Gee states that “a classroom where learners did not choose to be there and where an authority figure grades everyone else is not an affinity space and cannot be one” (Gee 2015: 127). Technology has enabled literacy to thrive outside of such restrictions, where Gee notes (among other things) that there are many routes to status; people are not segregated by age, gender, race, class, or expertise; leadership is porous and roles are reciprocal.

Technology has also introduced the idea of gaming to literacy development. Gee recognizes this at the end of his book *Literacy and Education* (2015) and much of his research has focused on good games, i.e., games that have the ability to provide contexts for problem-solving, skills-based learning based on clear goals, instant feedback, collaboration, and enjoyment. Kurt Squire states that video games are “the heir to traditional print fiction” (Squire 2008: 106) arguing that the learning opportunities to be found there can be much richer and enable greater participation than the opportunities in schools which are still “shackled to literacies of print” (Squire 2008: 106). MMOs (massively multiplayer online games) are also seen to enhance learning (Plass et al. 2015), enabling participants across genders, socio-economic boundaries, age, and color to

collaborate in their endeavor. They are based around questioning, collaboration and play yet those involved in such social practices need a significant amount of learning and often require mature print literacy skills to understand and interpret the rules of the game.

Other literacy practices that have been enabled due to digital technologies include blogs, forums, trip and restaurant review sites, Tweets, and Facebook posts. These areas allow for many of the literacy activities already seen and are an integral aspect of most people's lives in the twenty-first century. There has been some research into mobile technology use in schools and where the focus has been on action learning, authentic learning, experiential learning, and social constructivism, the outcomes have shown that mobile technologies, such as iPads, can increase collaboration between teacher and student, increase effective feedback and increase face-to-face interaction between teacher and student (Falloon 2015; Genlott and Gronlund 2016). In some classrooms where research has been carried out, the focus has been on pupil autonomy, social constructivism, real world practices, and extended classrooms (Clark and Luckin 2013). All of these literacy practices can be seen to be highlighted in the research on mobile technologies and can be seen to be beneficial to many of these practices.

Research notes the social capital and the social and civic benefits that can come with social networking (Ellison et al. 2007). It can be an emotional outlet for school-related stress and validation for creative work, as well as aiding school-related tasks, through group chats and instant messaging. Research has shown that some pupils who may be reticent in speaking in classrooms gain more support when they are able to collaborate with peers outside of this environment and in a space where they feel they can have more confidence without a figure of authority judging their questions and answers (Riddell 2017); these students can seek reassurance through these media and also gain knowledge and expertise from peer-to-peer sharing. Research has linked social capital (that can come with positive Facebook use) with academic achievement.

Correlations have been seen between Facebook use, where Facebook is used creatively rather than passively to check others' posts and look at photographs, and higher standards of traditional literacy used in examinations.

Research into the use of Twitter in higher education shows that Tweeting can allow for real time communication, enable authentic interaction between students and teachers, and provide an opportunity to promote learning (Gao et al. 2012). Microblogging use can expand the learning community and involve a greater range of experts to interact with learning communities. It can help real time reflection on learning practice and enable social constructivist learning. Some research showed its use in arts classrooms where students tweeted as their character in the play (McWilliams et al. 2011), other research suggested that Twitter use reduced isolation and helped interaction among students who were less confident (Gao et al. 2012). As well as a useful administrative tool, microblogging has also been shown to help increase memory for important concepts being taught (Blessing et al. 2012).

Literacy and Meaning Making

However, making meaning is the very bedrock of literacy, whether the definition focuses more on the social and participatory or on the individual and psychological. Despite the focus on the social and participatory above, especially through the lens of New Literacy Studies, there is still a need for theories to study the development of literacy practices in school settings to enable students to make meaning in a variety of learning contexts, especially in relation to digital technologies, and to help students engage with higher forms of learning and academic language and practice. Donald Leu, with the New Literacies Research Team at the University of Connecticut, recognizes the need to build a relationship between New Literacies Theory and the stable and common elements of traditional literacy for new social practices to be efficacious for learning (Leu et al. 2009). Much of his extensive research into digital technologies and literacy development combines

these perspectives and is integral to Online Reading Comprehension Theory (Leu et al. 2009) where he defines reading on the Internet as a process of problem-based inquiry.

Leu points back to the history of literacy (Leu 2006), noting the research of Havelock and others cited above, and notes that cuneiform technologies, papyrus scrolls, hand illuminated Bibles, and the mass publishing of books have all defined the nature of the literacy practices of their periods and all required new literacies to harness their potential. He has stated that the Internet is not a technology issue, but a literacy issue and despite believing that literacy is a deictic construct, ever changing in a technological society, his research recognizes that there are core elements in engaging with the digital technologies seen in the research above, to enable meaning-making to be more successful. He and others from the New Literacies Research Team point to five processes which will involve additional skills and strategies to enable meaning-making and communication: reading to identify important questions; reading to locate information; reading to evaluate information; reading to synthesize information; and reading and writing to communicate information (Leu et al. 2009). In focusing on the idea that the Internet is a literacy, rather than a technology, issue, Leu has emphasized the necessity of embedding such literacy practices as the five points above, across all subject areas in schools. To enable students to become successful processors of online texts, researchers have seen that integrating such practices into curriculum and assessment in schools is highly valuable.

Multiple Documents Literacy

As Leu has shown, reading on the Internet rarely involves reading one text. Research into this area has become known as multiple documents literacy and a number of scholars have proposed models to enable students to become more successful in this field. Jean-Francois Rouet differentiates between “restricted literacy” and “extended” or “functional literacy” which he sees as the ability to use “documents in various contexts and for various

purposes” (2006: 192). Rouet’s work builds on the work of Kintsch (1998) whose Construction-Integration model of reading recognized that successful reading depends on building a textbase model from within the text and integrating it with prior knowledge to create a situation model. Meaning is therefore constructed through three processes. The first process involves encoding words and phrases, this is called the lexical or surface level. The second process, called the textbase level, turns such encoded words and phrases into propositions. The final process is where such propositions are linked to prior knowledge, enabling inferences and implications, known as the situation model level.

Rouet’s work has developed to include research into the importance of domain knowledge for successful text processing and the variety of metacognitive skills needed when processing multiple documents online. These skills can be seen in his MD TRACE model (Rouet and Britt 2011) and developed in further work which highlights the idea of Document Nodes. This work shows that successful processing of multiple documents includes the importance of recognizing source information such as author, date of writing, social context, biases and purpose of writing, as well as the ability to evaluate the content of the document – all these skills combine to create a mental model called a Document Node. A Document Node can link to other Document Nodes which can develop meaning through comparison or contrast, depending on the situation models that are created by the reader from that document. However, researchers note that the complexity of these tasks means that those involved in such literacy practices will need significant teaching and training.

Peter Afflerbach and Michael Pressley have done much work in metacognition, especially in the area of reading comprehension (Pressley and Afflerbach 1995; Pressley and Gaskins 2006; Afflerbach et al. 2015). Much of their work complements the work above seen in Rouet, focusing on strategies to monitor and evaluate text, task, and reader and how these strategies can be taught and modeled in the classroom. Their meta-analysis of research looking at strategies involved in

reading text (just before reading hypertext became widespread) has been instrumental in understanding the metacognitive skills and strategies when making meaning from text (Pressley and Afflerbach 1995).

Following from this research, Afflerbach and Cho (2009) identified strategies used when constructing meaning from multiple texts, under the categories: realizing and constructing potential texts to read; identifying and learning important information; monitoring; and evaluating (2009: 83–84). These strategies were seen to be important for success in this new literacy environment with its many challenges. Separating the strategies into distinct categories with a number of subcategories under each area, Afflerbach and Cho provided a helpful rubric to enable teachers and students to focus on specific strategies that might enable more profitable searching of multiple documents online.

More recent work by these researchers has updated these categories and refined the focus (Cho and Afflerbach 2017). Their continued study in this field has enabled them to divide the process of reading multiple texts online into two main areas, with specific categories and subcategories. These two main areas and their subcategories are given below:

Constructively Responsive Reading Comprehension Strategies for Multiple Digital Texts

1. Identifying intertextual links and making meaning from across texts
2. Monitoring the construction of intertextual relationships
3. Evaluating and sourcing multiple digital texts

Constructively Responsive Reading Comprehension Strategies Used during the Construction of Reading Paths

1. Managing information spaces and navigating toward useful texts
2. Building intertextual linkages and making meanings from hypertexts
3. Monitoring the construction of reading paths
4. Evaluating and sourcing multilayered links and texts

Cho and Afflerbach show that constructing reading from multiple documents can blur the distinctions between reading and writing as the reader is responsible for creating a new understanding and a new text, through the iterative processes seen above. Online reading involves significant self-regulation strategies to enable the reader to stay focused on the goal of the reading and to plan pathways to achieve that goal, despite the many challenges that online reading brings. These challenges include the variety of search engine results, the various genres to be navigated, decisions to choose hyperlinks within texts, and the ability to stay on task despite the hyperlinks being irrelevant to goal though interesting to read. Online reading, therefore, involves a range of metacognitive skills to enable a reader to assemble a coherent mental model from the various Document Nodes created, from the variety of text types and genres being read. This can be both exciting and challenging.

Cognitive Flexibility and Literacy Development

Cognitive Flexibility Theory (Spiro et al. 1988) helps to recognize where this kind of knowledge construction might fit in the process of education. Spiro and others note the difference between introductory and advanced learning and posit that there is an intermediate phase of learning between the rudimentary, simple, and superficial foundational knowledge and the advanced knowledge where concepts can be mastered and knowledge can be understood as more complex and nuanced, context dependent and fluid. Digital technologies and especially multiple documents literacy is perfectly suited to advance learning from the simple to the complex as the Internet is a domain where learners can experience multiple representations of the same topic and recognize that knowledge is not as simple and straightforward as foundational knowledge acquisition presents it to be. In his more recent work, Spiro again emphasizes that cognitive flexibility enables readers of multiple texts to “assemble” understanding from multiple perspectives to forward

deeper, richer learning through making multiple connections and synthesizing relevant information to broaden appreciation for what is being learned (Spiro et al. 2015).

The emphasis on cognitive flexibility for advanced learning can be seen in multiple documents literacy research. The recognition that knowledge is uncertain and evolving is a significant aspect of successful construction of meaning from multiple documents online. The area of epistemic beliefs can be seen across the research as an instrumental aspect to successful meaning-making (List et al. 2013). Researchers have noted that focusing on this aspect can have significant benefits for broader and deeper learning. Braten and Braasch (2018) overview studies focusing on processing texts with conflicting information and outcomes and suggest that where readers encounter such conflicts they are more likely to process the material at a deeper level and with more ability to remember what has been read. This higher-level processing can be seen to be even more marked when the information conflicts with prior held beliefs.

When Spiro points to cognitive flexibility, he recognizes that it is to enable students to move beyond introductory learning and to enable learners to move towards mastery. Digital technologies can enable this more advanced literacy, but Susan Goldman notes that Internet technology has raised the standard for what it means to be literate (Goldman 2015). In the past, a student would not have needed to use such advanced literacy skills until working on research papers at university. At school, there would have been a bounded source of information, from a class or school or perhaps even the community library. The amount of information would have been limited and the evaluation of text authority and accuracy would have been the purview of editors and publishers. Digital technology has changed such literacy practices beyond recognition. Goldman states that literacy has not changed, but our expectations of literacy practices at certain stages of education have changed and expectations have increased exponentially (Goldman 2015: 90, 91).

The Role of the School

David Olson (2009) reminds his readers that the responsibility for developing the literacy needs of young people lies with the school. The responsibility to learn is the pupil's, but he states "Although many agencies have some responsibility for making it possible for learners to acquire literacy skills, in modern societies, the school had been charged with the responsibility for developing those competencies" (2009: 574). Much of the research seen above, not only on multiple documents literacy, but also on digital technologies and applications, has been undertaken with undergraduates. However, if Goldman is correct in recognizing that the expectations for literacy skills that were once the domain of higher education have now been shifted into the secondary sector and for some, even into the elementary or primary years, it is important to contextualize the literacy needs and skills and how to address these in a digital culture that is increasingly part of the school classroom.

Julie Coiro has helped to develop strategies to enable high school students to engage with multiple documents successfully (2011). Her early research with Elizabeth Dobler, in 2006, looked into 11 sixth graders who were skilled and experienced in reading on the Internet. This early work (Coiro and Dobler 2007) helped bring recognition that literacy skills needed for successful meaning-making overlapped significantly with skills needed for print literacy, but also made some processes more complex, such as self-regulated reading and inferential reasoning. In more recent work, Coiro and others have developed an Online Inquiry Tool (Kiili et al. 2016) to help students scaffold their learning online, especially helping with planning, identifying arguments and counter-arguments, critical evaluation, synthesizing information, and composing an argumentative text. This tool is clearly closely linked to the five key elements noted by the New Literacies Research Team seen above and linked to the work of Donald Leu. His continued research has also focused on teenage literacy development in the realm of digital technologies and high school classrooms (Kiili et al. 2012; Kennedy et al.

2016). His work highlights the benefit of working collaboratively to enable higher order questioning and deeper reading and to avoid the more superficial mode where teenagers tend to “locate and gather information” without critically thinking and evaluating. However, Leu recognizes that this collaborative learning and social construction of meaning, though leading to better essay performance, takes significantly longer and can be problematic in classroom situations and especially in contexts where school systems are focused on high stakes testing.

Challenges to Literacy Development from the Digital Culture

Much of the research noted above in relation to literacy development and multiple documents has focused on metacognitive as well as on cognitive skills. However, research shows that these can be impeded by the digital technologies that are an integral part of the culture in which literacy development is taking place (Aagaard 2015). The digital culture can be seen as one of distraction, where research has shown teenagers constantly interrupted from their studies by social media alerts on mobile telephones and computers (Taneja et al. 2015). However, one metacognitive skill that is integral for the ability to construct meaning from what is being read is the ability to attend and monitor what one is reading, especially when there are multiple texts to read or hyperlinks to click or pop-ups that distract in the digital realm. Attention is needed if readers are going to be able to question texts, recognize and repair misunderstanding, and make connection with prior learning and with other texts to synthesize or to recognize counterargument, to read nuance and complexity. Despite the necessity of paying attention to enable comprehension construction and meaning-making, recent studies have found that reading onscreen leads to increased distraction (Baron 2015). Baron surveyed 82 undergraduates and 90% said they were more likely to multitask if reading on screen. Only 1% said that they would be more likely to multitask when reading the information in hard copy. When

given an opportunity to respond to open-ended questions about aspects of reading on screen which they least liked, the respondents volunteered answers which significantly focused on cognitive reasons (91%), complaining that reading onscreen led to greater distraction and a lesser ability to absorb the material. However, research also shows that “the proportion of study time spent attending to relevant information during Internet navigations [is] a significant prediction of retention” (Desjarlais 2013: 701). The research seems to suggest that paying attention on screen is more challenging, yet paying attention on screen is a necessary skill to retain the information found there.

Not only is attention a necessary metacognitive skill which can be more difficult when engaging with digital technologies, but other metacognitive skills can be seen to be affected through technology use. Research into multiple documents literacy shows that prior knowledge can be the single most important factor in meaning-making after decoding. Patricia Alexander and others have noted this in their research and she states that “prior knowledge influences the reading act and is affected by each reading act. So as they read, students are expanding and building their base of knowledge about the world, about texts, and about themselves as readers” (2012: 262). However, research into the cultural reading habits of those immersed in a digital culture shows that much of this general knowledge which used to be gleaned from newspapers and broadcasting is now encountered online, but in a more intentional way (Pariser 2011).

Blogs and forums have been mentioned above as types of new literacies afforded by the democratizing of digital spaces; however, research shows that these are often echo chambers where those of like mind can gather together, rather than places of informed debate with those of different opinions (Poell 2009). Research into the use of social media for electoral campaigning has also shown the targeted nature of such information where those on certain social media sites might never encounter views of a different political opinion (Tambini 2018). Much of the news that teenagers consume is viewed online. Yet here

again there is a further reason why online news might be problematic. The term narrowcasting has been used for the type of news media online users consume and, as a pun on the traditional broadcasting, it differentiates itself from traditional news in that it is self-chosen and self-edited; thus, it can often be narrower in focus. All these platforms allow for a broadening of knowledge and an ability to widen one's understanding of self and the world, but the research shows this might not always be the case and this narrowing of knowledge and understanding of the world has consequences for literacy development (Alexander 2005).

This can be better understood in the light of knowledge gap theory (Trichenor et al. 1970) which suggests that despite the amount of information available in the digital culture of mass communication, it will not narrow the knowledge gap, but expand it. The research shows that those with knowledge, such as political or cultural knowledge, will be able to broaden their understanding and develop their appreciation because of the access to information afforded by the Internet (Wei and Hindman 2011). Foundational knowledge enables more specific search terms and allows for the creation of deeper learning. However, those without such knowledge will be less able to search for more insight; they will be constrained by their lack of foundational knowledge to enable them to create appropriate search terms, critically evaluate what they encounter, or know which are the pertinent hyperlinks to click to lead them into broader understanding. In this respect, the knowledge gap will grow, analogous to the Matthew Effect in language acquisition (Stanovich and West 1989), where those who have, gain more, and those who have little are impeded in their ability to develop their language and learning through less ability to engage with knowledge construction that comes with higher levels of literacy. In their research into knowledge gap theory and the digital environment, Wei and Hindman (2011) concluded that: "...education is the only demographic factor that makes a difference in predicting internet access and information use. ... Besides general education,

training programs that aim to improve people's cognitive skills and internet literacy will be possible ways to reduce the digital inequality" (2011: 28, 30).

This lack of wider knowledge can also have implications for the ability to evaluate sources. The ability to evaluate sources comes from a wider understanding of aspects including source type, publisher, period and context of writing, and knowledge of author. Recent research has shown that students find it difficult to recognize political bias when they are not familiar with the particular leanings of specific news sources (Riddell 2016). This not only has implications for literacy development, but specific political literacy and this can have consequences for the democratic process. Scholars such as List et al. (2013) show that students also tend to choose accessibility of length and content when in time-bound classroom situated tasks, over other more critical ways to evaluate text. This can lead to students choosing self-generated and self-published material with little authoritative value, over more challenging, yet more informative and reliable texts.

As has been seen from the various research above into the cognitive and metacognitive strategies and skills needed for successful processing of multiple documents online, which is the main area where literacy and technology intersect, there is a lot involved in reading online. This too can prove challenging because of the cognitive load that it can bring. Although recent research has begun to look at this area in the light of readers with special learning difficulties, such as dyslexia (Anmarkrud et al. 2018), there is still little research into those with specific challenges engaging with multiple texts online. However, research to date which has looked at competent readers in the digital environment has shown that the variety of tasks involved in strategic processing can lead to cognitive overload (Salmeron et al. 2018).

Cognitive Load Theory was developed by John Sweller during the 1980s. Much of Sweller's work on working memory emphasizes the importance of prior knowledge to reduce cognitive overload (Sweller 1988). Again, this links to the

knowledge gap theory and has implications for our understanding of the relationship between certain literacy practices and certain technologies. Research has shown that cognition can be overloaded even if a person is trying to concentrate on one task to avoid such overload (Nicholson et al. 2005). This research shows that “Empirical evidence indicates that the mental process of ignoring something requires cognitive effort, that is, individuals must constantly remind themselves of what it is that they are trying to ignore in order to expend the effort to ignore it” (2005: 7). This theory can help educators understand the impact on learning if cognition is overloaded due to the amount of distraction in a technologically saturated environment.

Another theory linked to cognitive load that can also play a significant role in understanding the impact of digital technologies on literacy is Lang’s Limited Capacity Model (2000). This aspect of cognitive load theory has been used by many researchers looking into the effect of digital technologies. Although originally based on research into how viewers react to the medium of television (Lang 2000: 47), many of its features are relevant to analyzing the online world. Coiro and Dobler, cited above, showed the relevance of the Limited Capacity Model in their study, when considering what children could attend to when reading web sites and search engines. The model posits that there is a limit to the information that people can process. Lang focuses on three specific subprocesses: encoding, storing, and retrieving. She suggests that resources are allocated to these subprocesses independently and, as a result of these resources being limited, one or more of the processes may suffer if another needs more attention. This clearly has implications for literacy development and researchers have shown how overloading working memory can have consequences for understanding and longer-term memory (Pass et al. 2004). Research into the use of Microsoft PowerPoints in higher education (Worthington and Levasseur 2015) and the design of virtual learning courses (Mayer and Moreno 2003) has shown that serious consideration has to be given to cognitive capacity to ensure that literacy

development is not impeded through cognitive overload due to various digital practices.

Conclusion

This article has shown that literacy and technology are intimately related. Historically, technologies such as alphabetic script, the printing press, the telegraph, and the television have all led to changes in literacy development. Twenty-first century digital technologies are no less integral to literacy practices, as has been seen in this article, whether those practices focus more on the social and relational or more on the cognitive and psychological. Despite the variety of new literacies, many enabled by new technologies, this article has illustrated the need for traditional literacy practices to ensure that citizens have the skills and strategies necessary to succeed in the literacy practices of their choosing. Indeed, this article recognizes that although technologies have enabled new literacies to abound, they have also added challenges to traditional literacy practices that make it necessary for new skills to be learned for successful literacy development, whether in school or in other social practices beyond the classroom. Pitting traditional literacy against new literacies is as unhelpful as pitting technology against literacy. However, for literacy practices to develop and succeed, the challenges as well as the benefits that technologies can bring to the context of literacy must also be realized. When these challenges are taken seriously, technology and literacy can continue to advance together for the benefit of all.

Introduction

The “maker” and “STEM” (Science, Technology, Engineering, Mathematics) movements have recently become an outsize influence in the

discourse around science and mathematics education in the English speaking world, if not globally, not least due to the juggernaut of United States media and business interests’ reiteration of its message (of the confidence in its innovative practices for the future). Part of its appeal must lie in its promises of economic success to the communities that “get it right”, not to mention the human fascination with new devices and technologies that are supposed to lift us from the drudgery of hard work. In this chapter, I seek a different perspective to the essential problems of science education and propose how educators may meaningfully integrate a design and engineering perspective to learning, idiosyncratic school system concerns notwithstanding. In essence, there is a truly novel challenge being posed by the STEM and maker movements and the technological progress that they represent – the uniquely human ability for insight and knowledge generation compels us to consider deeply how we can teach students to make new knowledge. Some perspectives on the nature of knowledge and learning are used here to develop a case for what this form of learning ought to achieve and what it may look like.

Exciting Times Ahead?

Simply judging by the approximately 600,000 Google Scholar search results for “maker movement” in January 2018, it is probably an understatement to claim that the movement has attracted widespread attention around the world. The outsize influence of

the Californian economy, specifically its high technology sector and their seemingly effortless process of creating money out of thin air have no doubt been significant sources of inspiration for teaching and learning. It can be easy to agree with claims that we are in a new information age, given the ease and ubiquity with which information is stored, retrieved, and manipulated. The manner in which designs are created, exported, made ready for manufacture, shared, and reused have concomitantly ridden upon this information age; interesting technologies have also emerged surrounding the fabrication and manipulation of materials, all of which appear to point to bright shiny futures indeed for any and all who will join the campaign. Yet, as they say, not all that glitters is gold. For economies seeking to replicate the success of California's Silicon Valley, the reductionist approach of finding the "active ingredient" of a particular approach to education and applying it like a salve to another patient will encounter the complexity of educational interventions – where all "layers" of analyses, from the cognitive to the sociological, interact nonlinearly and matter. This is, essentially, a curriculum question, and depending on one's perspective, it can be heartbreaking to learn that despite changes to social circumstances over many decades, the fundamental relationship of schooling to societies has, in many ways, not changed significantly. However, this observation should not prevent our attempts to actually do so; always carefully paying attention to the educational problem first and not attempting to bring technical solutions in search of problems to fix.

The problem with curriculum arguments that originate outside of educational circles may be a lack of understanding of the educational context. It is not uncommon for business leaders to lament that schools need to be run like businesses, badly underestimating the level of challenge posed by public schooling (Cuban 2004); yet we see no end to wealthy individuals and corporations insisting (at least in the United States) that they get their tax dollar's worth of learners prepared to enter vocations in their industry; in that regard, the current discourse around twenty-first century competencies do not sound very different from the shrill scare-mongering of "unilateral educational

disarmament" of the 1980s (Bracey 2003; Gallagher 2013; National Commission on Excellence in Education 1983). The point of the foregoing is to direct the reader's attention to the fact that education is a heavily contested political ground, and that it is not uncommon for societies to demand that schools solve all manner of social problems (Labaree 2008), including those of individual and communities' successful participation in future economic activity. Often, these problems are not education's to solve – there are far greater factors determining success than purely one's preparation for the world of work. We should rightly be sceptical of efforts to foreground STEM in the classrooms simply because of some variant of "the future demands it". Unfortunately, as Burbules (2016) points out, we in education appear to have an occupational hazard: because in our working with growth and change, it becomes second nature that we celebrate newness. Because of the apparently unceasing nature of technological "progress", it becomes virtually inevitable that technologies become perceived as possessing particular pertinence to "solve" all manner of problems, real or imagined. Yet, if the history of technology in education has any bearing, there is no shortage of well intentioned technologies which promised to revolutionize schooling, but have not (Cuban 2001). The risk for our moment in time is no different; and in some circumstances, it is easy to discern the formation of an unsustainable bubble of hype. The fundamental challenge that can be posed by technological interventions need to be considered at the level of the cultural – if the hypothesis of a certain "law of amplification" holds, we need to understand changes to practices as only being amplified by technology, and that the hard work of changing practice needs to precede its amplification (Toyama 2015).

Rather than jump onto the bandwagon of making, makerspaces, and STEM education, it is important here to consider what may be truly innovative and meaningfully pertinent to science education, keeping in mind its persistent problems. The strategy for this chapter is to convince the reader of the nature of the educational problem

generally speaking, and the futility of universal solutions. This situation arises out of the nature of solutions to social problems. Having said that, however, it can be possible to unironically claim that there is nonetheless a certain subclass of problems, which confronts learners of the natural sciences. These problems arise out of the nature of the knowledge itself. It is then upon the local implementers of curriculum to carefully design learning goals, contexts, and methods to achieve locally sufficient solutions that take into account ontological and epistemological constraints of knowledge in the natural and *artificial* sciences.

Curriculum Problems Are Wicked Problems

When carefully considered, the advocacy of STEM education, making, and makerspaces needs to be thought of as a curriculum proposal. Proponents of STEM are essentially claiming that, among other things, students ought to learn STEM, how to make things, and that there ought not to be distinctions between the knowledge forms. Not surprisingly, at least popular proponents have pointed to the success of the Californian economy, ostensibly based on STEM innovation, or innovativeness in general, as a reason to adopt the practices of its most successful exponents. While there may be good reasons to suppose that some of these practices are truly novel and contributive to economic success, there are also significant reasons to be sceptical of some of the more excessive claims. California and the United States in general have been the beneficiaries of a particular confluence of conditions that are historical contingencies and not easily replicated anywhere else in the world. Not having one's infrastructure destroyed by massive wars and being able to attract the world's intelligentsia in the process are certainly helpful conditions for success. What is perhaps less well known, but not less important, is an ability to selectively ignore the contradictions and hypocrisy of advocating a self-reliant "bootstrapping" mindset, while remaining silent about the huge

handouts from the military-industrial complex; or advocating a belief in the emancipatory potential of new information technologies, while simultaneously being responsible for "technologies of freedom [...] turning into the machines of dominance" (Barbrook and Cameron 1996).

This is not to say that there is a lack of meaningful forms of knowledge that can be used in different contexts, but rather that there ought to be a careful adaptation and use of principles derived from one context, in another. For instance, Lindtner and associates (Lindtner 2014, 2015; Lindtner and Lin 2017) document, among other things, that indigenization processes modify the supposed participatory ideals of making to suit idiosyncratic political projects; that making can become discriminated into craft-hobby versus industrialized versions; and that maker culture can provide opportunities for people to creatively reinvent visions of self, not necessarily constrained by existing public discourses. Making in public makerspaces has also been documented as not being very much distinct from serious leisure pursuits (Stebbins 2009) such as gardening or carpentry (Davies 2018; Toombs et al. 2014). The problem for education here is to discern whose vision and values of what STEM and making constitutes is most appropriate for schools – why, for instance, should a school focus attention on a particular device or engineering sub-discipline when the local industrial community is more interested in solving other kinds of problems? Significantly, the general form of this problem is that of the wicked problem (Borko et al. 2008; Coyne 2005; Rittel and Webber 1973): essentially intractable, lacking in general solution, only amenable to case-by-case "good enough" transient solutions that create their own follow-on problems. Curriculum solutions, as with many solutions to design-based problems involving numerous competing interests, are inevitably wicked, and necessarily involve compromises to achieve stated or actual goals. The task for the educator considering making is to strike a locally acceptable compromise; to that effect, what follows are some possible goals and their costs and benefits.

Making for What?

Perhaps the most intuitive application of making and makerspaces is as a site that may ostensibly serve as a means to get students engaged in the learning of STEM. Here, making in itself is likely to be perceived to be of somewhat lesser value to the acquisition of STEM curriculum goals. Making could also be used as a means to acquire aspects of (functional) design and engineering competence, and also as a way to demystify technological devices. In concert with the arts, the moniker of STEAM (STEM with the Arts), the creation of aesthetically pleasing interactive art objects can serve the goal of weakening the boundaries between disciplines. Indeed, there has been much clamor for such forms of weakening, especially with the rise of “design thinking” as legitimate curriculum goals. Design, as a relative newcomer and out of place in contrast to the traditional disciplines that define school (broadly, literacy and numeracy), is likely to pose significant challenges to traditional schooling due to its loose boundaries. Design competence can take the entire gamut from architectural, engineering, fashion, and so on to many others. However, it may be useful to note that design leaders offer broad characterizations of good design as meeting at the confluence of “technical feasibility, social desirability, and business viability” (Kelley and Kelley 2013), or that design competence requires designers to make what are essentially value judgements, prescriptive statements of what ought to be, that are necessarily distinct from descriptive statements of what is (Nelson and Stolterman 2003). Learning design and making requires a certain reimagining of the curriculum boundaries of schooling – while it is not science, not art, not anthropology, nor sociology, it draws from these rich disciplines and transcends them through a creative process that does not originate from any of these disciplinary bases. On the other hand, while it can be easy to get caught up in the buzz surrounding “design thinking” as the contemporary equivalent of “scientific thinking” in times past, it is nonetheless important to acknowledge the intellectual debt owed to the “traditional” disciplines. Without an accurate apprehension of

the nature of reality as revealed by the natural and human sciences, it would be much harder to make value statements about how an ideal design ought to be. The response to “Why make?” could take the form of three purposes: as a context for learning; as a means to acquire design competence and dispositions; and as a means to learn about the gap between theory and practice. These will be elaborated as follows.

Making as a Context for Learning

As mentioned, this approach to making is perhaps the most common and intuitive to educators. The contemporary tools and technologies present unique affordances to schooling that may provide opportunities for forms of learning only previously dreamt of. As with revolutionary information and communication technologies that have changed the way learning may be facilitated, proponents of making with contemporary tools suggest that these tools can, among other things, serve as a form of “Logo, for atoms” (Blikstein 2013; Martin 2015). They refer to the computing tool, Logo, designed to teach programming by having its users take control of a symbolic turtle, and providing instructions to cause the turtle to move in various ways. The kind of learning privileged here may be aptly summarized by the quote attributed to Seymour Papert: “Constructionism shares constructivism’s connotation of learning as ‘building knowledge structures’ irrespective of the circumstances of the learning. It then adds the idea that this happens especially felicitously in a context where the learner is consciously engaged in constructing a public entity, whether it’s a sand castle on the beach or a theory of the universe” (Papert and Harel 1991). With making, an instructional approach could be to create structured opportunities for students to confront the limits of their own theoretical structures. This could take the form of investigative activities that capitalize on students’ curiosity, by introducing discrepant events that challenge students’ perceptions of what constitutes “normal” physical behavior (Lawson 2010). Such an approach is certainly not new (White and Gunstone 1992); what is more novel is perhaps the manner in which we now are able to hand over to students

the “means of production”, in that the flexibility and capability of tools available to students allow for significant student input into the experimental design and the possible range of parameters. While in the past teachers may have been limited to setting up experiments with data loggers and their proprietary sensor probes, a contemporary microcontroller can accept a wide range of inexpensive sensor modules, and be open to more fine-grained control and programmability using programming environments which allow for such features. If the learning goals for such kinds of making remain the acquisition of expertise in traditional pen-and-paper standardized assessments, there stands a significant risk that these activities will not go far enough to change the shape of schooling. While this might sound obvious, the conservative capacity for school systems to remain unchanged should not be underestimated. At some level, the lower ambition models of instruction in making may resort to versions of the so-called “keychain syndrome” (Blikstein 2013), so called because a common first activity for students learning 3D printing is the production of keychains with their names or personalization on it.

The expansion of goals of schooling to also include some form of understanding about the functioning principles of technological devices needs to be considered an important goal of advocacy for STEM and making. However, such an approach needs to be carefully considered. The political costs of dedicating limited school time on learning technologies that have no future relevance can be high enough to cause administrators and educators alike to stick to “tried and true” conservative goals. Considering the recent history of trends in technology, it is not hard to notice patterns of increasing hype and rhetorical urgency about the necessity of equipping our youth for a future of computers, microelectronics, genetics, internet applications, and game design. Equally predictable has been the gradual fade into the background as the Next Big Thing arrives. It should not be surprising that, as Cuban (2001) surmises, the rational strategy for administrators would be to simply button down and wait for the storm to pass. Such an approach is certainly not

completely defensible, but the form of this argument, in seeking the verities “eternal, changeless, possessing a certain indefinable and imponderable something whose essence is timelessness” (Peddiwell 1939) is definitely not new. While we may leave the curriculum theorists to debate on the nature of knowledge, a provisionally acceptable position for this problem may be advanced: we ought to educate students about technology, sufficiently that they may be empowered enough to be more than its casual users, but not so much as to lose sight of the transient nature of technological tools. The goal, if we were to adapt Arthur C. Clarke’s (1977) dictum that “Any sufficiently advanced technology is indistinguishable from magic”, must be to empower individuals to demystify these boxes of magic. Here, approaches deriving from the hacker mindset of getting down to the bottom of things, to metaphorically and literally opening up the boxes, to reconsider how particular implementations of ideas can be altered, adapted, and improved (Bratus 2007; Grand 2006) can be useful indeed. Extending the black box analogy, it may be useful to consider the goal of this form of education as developing in students the dispositions and abilities required to inquire into the inner workings of black boxes, and to develop models and functional equivalents to *classes of devices* of interest, rather than to necessarily become connoisseurs of one specific device. With little doubt, this will involve students gaining expertise in one instance of a device; however, it should be considered incomplete if this is all that is acquired. To be sure, one aspect of the “hacker mindset” – that of only needing to be “good enough” for the task at hand – can be detrimental as a learning disposition. If we wish to educate students so as to expand the boundaries to which they may take action in the future, we may want them to know that there are problems for which prior solutions have been considered, and that there is no need to reinvent the wheel every time an apparently new problem arises. Ultimately, this remains a core tension of learning: the balance between the need to reproduce culturally significant forms of knowledge and nurturing the ability to create new ones to respond to problems as they arise.

Making to Acquire Design Competence

Design expertise can be mysterious in no small part due to its rather recent heritage compared to the more established disciplines. As alluded to above, design is a transdisciplinary practice, in that it draws from diverse disciplines to arrive at a set of insights with emergent properties that may not be predictable from a pure study of the disciplinary bases. For instance, while antenna design for smartphones is ruled by the physics of microwaves, nothing in physics could have prepared designers for the manner in which telephones were held; similarly, nothing from human factors study could have predicted the magnitude of signal attenuation caused by human flesh in contact with radiating antennae. If we were to expand the scope of design to cover all manner of possible designs, covering the gamut of knowledge from architecture to zoo habitat design, it would seem impossible to characterize the diversity of expertise for designers. Nonetheless, if one were to take the wide view, it may be possible to discern patterns uniting acts of design. In common, design studies form a science of the artificial (Simon 1996), in that design's interest is in the interface between the goal that humans may intend for an artifact to solve, and the internal mechanisms that may bring about the goal. Such behavior is perhaps the defining characteristic of human and sentient tool use: a concern for bringing about the solution of a perceived problem in a manner consistent with a particular desire, and a method of selectively organizing phenomena in a hierarchical manner to bring about the desire. For instance, while a smartphone is a complicated mechanism, the operating system designer can do his work without much knowledge of the exact functioning principles of the processor integrated circuits (Although the recent Spectre and Meltdown malware attacks point to a possible vulnerability in this line of thought.). In what must seem like a contradiction to the advice above, it can be perfectly acceptable for designers to ignore the details at a deeper level. To be sure, such a practice is also routinely carried out in entire disciplines of the natural sciences: ecological behavior can be studied with little knowledge about the chemical functioning of the individual

organisms, let alone the atomic interactions that make up the biomolecules. The point here is that the process of design can be thought of as the manipulation of sufficient layers of complexities as needed to cause desired changes at the level of interest. A manner of thinking that can abstract the pertinent details, while ignoring those that do not matter to the problem at hand is central to the ability to control sufficient complexity to achieve the designer's desired goals.

For instance, the development of circuit tiles or equivalent means of rapidly connecting electrical and simple electronic circuits can quickly abstract details away from novices, the goal of which could be the acquisition of an overall sense of how devices could be built up using electronic elements. Such systems utilize magnets, physical interlocking shapes, or other means to ensure that circuits cannot be misconnected, and hence reduce complexity of the learning task for students. By treating each circuit element as a black box, and selectively probing these elements to discover what they do in concert with other elements, students can be free to make circuits that fulfil particular functions, rather than be bogged down by the details of the specific limitations of how electronic elements have to be connected in particular ways. In this sense, the timeliness of the maker movement has been aided in no small part by numerous technologies that have increasingly obscured the internal workings of devices, in exchange for a supposed gain in users' abilities to achieve design goals. Website authoring tools, three dimensional (3D) printing, and the entire movement of downloadable designs leading to adapted designs, digital photography and videography: all these and other technologies offer users the Faustian bargain of an ease of use so as to focus on the emergent layer of intentionality. The flip side, however, is the common refrain that the "younger generations" no longer have the aptitude for repairing things, and is also somewhat ironically a motivating call for the STEM/Maker movement. In a sense, such a critique is somewhat unfair, as the devices and systems being manufactured for sale are seldom serviceable by hand, and manufacturers, often motivated by profit, are placing barriers in the way of

repairability. Nonetheless, the critique is in the right direction, either for environmental reasons (owing to the finiteness of material resources), or for demystification and empowerment reasons as mentioned above.

Making as Performance

Perhaps least-well elaborated theoretically, but most often intuited as a significant reason for supporting making and the STEM movement, is the performative aspect of knowledge. Here, attempts at identifying the phenomena include the notion of the theory-practice gap, the realization of the importance of tacit knowledge, and more recently, attempts to explain learning from an embodied cognition perspective (Barsalou 2010; Goldinger et al. 2016; Shapiro 2007). The central tension here is between knowledge-as-representation, and knowledge-as-performance; or, as observed by Gilbert Ryle over 70 years ago (Ryle 1946) the distinction between knowing-that and knowing-how; or, being able to know more than one can tell (Polanyi 1966/2009). It would be fair to say that, with the relative ease by which a representational assessment may be conducted via a paper and pencil task, the demands for efficiency of school systems have largely made this form of assessment and instruction the default mode. For a time, such an approach was easily the preferred mode, as it seemed that the higher paying jobs were being reserved for the people with competence in symbolic rather than material manipulation. Yet, with increasing automation and the slow but inevitable creep of symbolic processing technology into the workplace, it is hardly surprising to learn about the contemporary capabilities of such technologies (Carr 2015), and the goals toward which they have been put. It appears that the financial incentive to remove highly trained artisanal labor, (be they expert wheel builders, burger chefs, or more recently, radiographers), and replace them with a serial process of arbitrarily small steps each accomplishable by the lowliest paid unit, is simply irresistible to capitalists (Crawford 2009). This process of “cognitive sedimentation”, as Crawford calls it, appears to affect any kind of work process that is routinized; ultimately, it may have its roots in the Western line of thought that

finds it natural to have a dualistic separation of mind and body, form and substance.

This line of thinking can be referred to as *hylomorphism*, “from the Greek *hyle* (matter) and *morphe* (form). Whenever we read that in the making of artefacts, practitioners impose forms internal to the mind upon a material world ‘out there’, hylomorphism is at work” (Ingold 2013, p. 20). It is easy to fall into the trap of hylomorphism, especially since the promise of mass industrialization is, at least in part, the widespread accessibility of extremely sophisticated material designs brought about by the low cost mass reproduction of well designed plans to make them. It is hylomorphism at work when we see products labeled as being designed in one place, and manufactured in another. Yet, what is hidden from view is the expertise necessary to process materials to make these designs a possibility. These forms of expertise are precisely the kinds of expertise that engineers involved in manufacturing wish to preserve as their own and to distinguish from the kind of craft-based, one-off “making” more commonly associated with makerspaces (Lindtner 2015). Nonetheless, the intent here is to attempt to distinguish between manufacturing, an industrialized process of duplicating, and *making*, a more limited and creative performance that blurs the boundaries between form and substance, design and material, and subject and object. The contention here is, as with Ingold (ibid.) and others, the activity of making is necessarily a contingent process where the intended outcomes of the process of making is always inseparably connected with the trajectory of materials in their process of becoming.

While this may sound counterintuitive from the perspective of limited public understanding of the design and manufacturing processes, such an anti-hylomorphic interpretation of the processes of *doing* science may underlie a more accurate understanding of the tacit knowledge of science. In what Pickering (1995) refers to as the *mangle of practice*, scientists are always in the process of adjusting their goals (a process he refers to as accommodation) in response to resistances encountered in the pursuit of their scientific claims. In a follow-up volume (Pickering and

Guzik 2008), examples are fleshed out, of scientists who, especially because they are working at the boundaries of our knowledge, struggle continually with materials which continually resist the efforts of scientists to derive abstracted systems of representing and predicting their experiences with these materials. For instance, attempts to model, understand, and control the flow of rivers have resulted in no end of disappointment and loss of resources and even human lives as nature repeatedly reveals more and more ways to defy the human capacity for control. Pickering (2008) goes as far as to suggest that a new ontological metaphor for the natural sciences needs to be considered: from one of a project borne out of attempts to reveal the hidden secrets of nature so as to control it; to one where humans learn to take a mutual dance of agency with nature. As with dancing, the process needs to be interpreted as a mutual, *performative* give-and-take between the parties of human and material agencies as scientists learn how to accommodate impossible-to-anticipate material interactions within their explanatory frameworks.

The outcome of this line of reasoning compels us to rethink our curriculum priorities when it comes to the STEM disciplines. If the performance of science is to be considered at least as important as one's facility with its canonical representations, rudimentary expertise in purely technical procedures already part of typical programs in science will not be sufficient. How it is that we may be able to arrive at new knowledge claims, and the partial, interpreted nature of the behavior of natural systems needs to be a focus. While inquiry approaches have recently captured the attention of the science education community, perhaps less investigated is the role of human interactions with material agency in this process: how should educators, for instance, capitalize on the opportunities presented to learners when experiments do not proceed as planned? What opportunities for learning in science are missed when we insist on standardized materials, methods, and equipment to obtain canonically acceptable depictions of natural behavior? What other forms of scientific performances ought to be valued if we are to consider

this alternative ontological metaphor for the pursuit of scientific knowledge?

Conclusion: Is Making an Educative Activity?

It would be too glib to repeat the words of the more famous popularizers of making as an intrinsically learning activity (of which there are plenty); and yet too facile to say that the educative value of an activity ultimately lies in its instructional accompaniment. As for the complex phenomenon that education is, there are several interpenetrating layers for consideration that ultimately determine the ideal end state of our venture: that people learn. On one level, the sociocultural organizational patterns of making resemble sites where innovative making and design can be used, either to prepare students for potential sites of future work, or as actual alternatives to industrial-rational practices of schooling conventionally practiced. On yet another level, the psychological insights that one may obtain from a direct and physical interaction with a material reality can offer to students perspectives that are simply not possible to obtain through mediated forms of experiencing. Finally, the gains to society from communities who are empowered to understand the functioning principles of the background technologies that support their very existence needs to be considered a vital prerequisite of being a responsible, fully participating member of society. The question that ought to confront us now is how soon these practices can become as synonymous with education as the classroom and the blackboard currently are.

Introduction

Recent international surveys such as the Organisation for Economic Co-operation and Development (OECD) report *Students, Computers and Learning* (2015) highlight the wide gap in students' access to, and use of, technology in

secondary mathematics in participating countries. The OECD “snapshot” methodology in which 15-year-old students were asked if they (or their teachers) had performed a range of mathematical tasks using computers in the month preceding their completion of the Programme for International Student Assessment (PISA) survey revealed low levels of technology use (see Fig. 1).

However, these data revealed big differences between countries. For example, in Norway, 73.1% of students reported at least one of these uses of technology, whereas for Ireland, the figure was 17.6%.

While the OECD reports teacher and student usage, it gives no insight into the context in which this usage is taking place. A country's (or region's) policy for technology use in its mathematics curriculum (and the associated assessment regime) has long been cited as a potential catalyst or barrier to technology use (Hoyles and Lagrange 2009). For example, mandating technology use in examinations is a known factor that increases classroom usage by teachers and students. This article aims to reveal similarities and differences between the international policies and practices as a means to shed more light on the OECD data. There are two important caveats:

- National curriculum and assessment policies are dynamic, with varying timescales for review and implementation. As this study reflects the current picture, it cannot be assumed that the 15-year-olds that took part in the PISA study experienced the curriculum and assessment regime as reported.
- In some countries such as the USA, Australia, and Germany, there is wide regional variation due to locally mandated curriculum and assessment policies.

The categories used in the OECD survey reflect the international evolution of how technology is now being used within mathematics education. The following entries of the Springer Encyclopedia of Mathematics Education expand on the evolution of these uses with respect to technology types and design considerations

Mathematics Education and Technology, Fig. 1 OECD average use of computers during mathematics lessons (OECD 2015, p. 56)

(Freiman 2014a, b), the affordances of technologies for mathematics education (Hegedus and Moreno-Armella 2014), and the implications for mathematics curricula (Sutherland and Rojano 2014).

Technology is interpreted as a mathematical “tool” that offers a mathematical environment within which to explore, express, and communicate mathematical ideas. (For more on mathematical digital tools, see Monaghan et al. (2016).) Hence, it has many uses within the design, teaching, and assessment of mathematical activity, which form the main focus of this text.

As an example, consider Figs. 2 and 3, which show a digital resource for lower secondary students that aims to provide them opportunities to “Find out how the graph of a function changes, depending on its parameters,” one of the seven task types that feature in the OECD survey. In Fig. 2, the character “Shakey the Robot” has been animated to travel along the number line in real time. Simultaneously, the character’s position-time graph is plotted and the corresponding data-line highlighted in the table. The linear function that describes the motion algebraically is also

given in the form of an equation. Figure 2 is a “snapshot” of this motion when the lapsed journey time is equal to 2 s.

In Fig. 3, the simulation is shown in edit mode, which affords the student the choice to vary a number of parameters (start position, finish position and speed) by dragging hotspots or changing numerical values.

This resource, which is taken from the Cornerstone Maths linear functions curriculum (www.ucl.ac.uk/cornerstone-maths), has its antecedents in the work of Jim Kaput in the USA and has been extensively evaluated with positive impacts on students’ mathematical outcomes in a number of studies in the USA and England (Hegedus and Roschelle 2013; Hoyles et al. 2013; Kaput 1989; Kaput and Schorr 2008).

An alternative technology might be to use an online graphing tool such as Desmos (<https://www.desmos.com/calculator/56envakzbp>), a graphing software package or a graphical calculator. There is consistent research evidence to suggest that such technologies support students’ understanding of the function concept (Kieran 2014), although it is important

Mathematics Education and Technology, Fig. 2 “Shakey the robot” – a snapshot of an animated journey

Mathematics Education and Technology, Fig. 3 Shakey the robot – editing the animation

to highlight the key role of the teacher in the successful integration of such technologies in classrooms (Clark-Wilson et al. 2014). Consequently, this article also sheds light on the policy and practice concerning initial and in-service teacher education for technology use in mathematics in the different countries.

Although the main tenet of the article is focused on upper secondary education (14–19 years), it begins with a brief commentary on the policy differences regarding primary (4–9 years) and lower secondary education (9–13 years) as indicators of the varying trajectories of students’ experiences through their schooling.

Technology Use in Primary Mathematics Education

The majority of the 16 countries (or regions) do not mandate for the use of mathematical technologies in the primary mathematics curriculum, although the use of general, non-specified technologies is sometimes required. The exceptions are France, Portugal, Norway, Wales, and the state of Victoria in Australia.

Table 1 shows the distribution of countries and their technology use.

The French national curriculum includes a particularly forward-looking vision statement, which translates to:

The school contributes to the project of a society of information and communication for all by initiating, in partnership with communities and different actors, actions to generalise uses and develop digital resources for education. It trains students to master these digital tools and prepares the future citizen to live in a society whose technological environment is constantly evolving. (<http://www.education.gouv.fr/pid24307/les-programmes-de-l-ecole-elementaire.html>)

This vision is supported by a government department, the “Digital Education Directorate,” which provides links and resources for teachers to realize this aim. Furthermore, all trainee teachers in France are required to pass a Master’s level course on the use of technology for teaching and

Mathematics Education and Technology, Table 1 Tech-nology use in primary mathematics education (5–8 years)

	Technology use is mandated in the national/ regional curriculum	Technology use is optional in the mathematics curriculum
No standardized high-stakes testing	Australia (Victoria)	Germany
	France	Netherlands
	Norway	
Students can choose to use technology in some or all high-stakes mathematics assessments		Israel
Students are not allowed to use technology in any high-stakes mathematics assessment	Portugal	England
	Slovakia	Hong Kong
	Wales	Ireland
		Italy
		Scotland
		Taiwan
		Turkey

learning, although for primary phase teachers, this might not necessarily have a mathematical focus.

In Norway, a similar broad vision for mathematics exists that encompasses the role of digital skills:

Digital skills in Mathematics involves using digital tools to learn through play, exploration, visualisation and presentation. It also involves learning how to use and assess digital aids and tools for calculating, problem solving, simulation and modelling. It also means it is important to find information, analyse, process and present data using appropriate tools, and being critical of sources, analyses and results. The development of digital skills involves working with complex digital texts with an increasing degree of complexity. It also involves developing an increasing awareness of the new digital tools that exist for learning in the subject of Mathematics. <https://www.udir.no/kl06/MAT1-04?lplang=http://data.udir.no/kl06/eng>

Within the primary curriculum, this vision is exemplified within one of the content statements for geometry, where pupils are enabled to “make

and explore geometric patterns, with and without using digital tools, and describe them orally” (ibid.).

The approach to the assessment of primary mathematics varies internationally. Some countries require classroom-based teacher assessment (e.g., France, Norway), whereas other countries conduct high-stakes examinations at a national or regional level (i.e., England, Netherlands, Hong Kong, Singapore, Slovakia, Taiwan, Turkey, Wales). For those countries with high-stakes testing, none permit the use of technology by primary students.

Technology Use in Lower Secondary Mathematics Education

In the lower secondary phase (9–14 years), there is a shift to more mandated use of technology in the mathematics curriculum, with several countries typically specifying the use of spreadsheet, function plotting, and dynamic geometry software applications (i.e., all states in Germany, Portugal, France).

Table 2 shows the distribution of countries and their technology use in this education phase.

Again, some countries have offered a more visionary stance, such as Portugal:

All Secondary Schools must equip themselves as soon as possible with Mathematical Laboratories. The didactics for Mathematics in secondary education presupposes the possibility of using diversified materials and equipment: graphical calculators with the possibility of using programs; computers; data collection sensors for both calculators and computers. It is considered indispensable to use: graphing calculators (for regular classroom work or for demonstrations with all students, using a “view-screen” calculator); a computer room with software suitable for work as regular as possible; a computer connected to a data-show or video projector (for demonstrations, simulations or classroom work with all students at the same time). (Ministério da Educação e Ciência 2001, pp. 14–15)

In this phase of education, the shift is toward optional use of technology within mathematics assessments, which seems to accompany more explicit curriculum guidance for its use. The trend is to permit the use of scientific and/or graphical calculators within high-stakes testing.

Mathematics Education and Technology, Table 2 Technology use in lower secondary mathematics education (9–14 years)

	Technology use is mandated in the national/ regional curriculum	Technology use is optional in the mathematics curriculum
No standardized high-stakes testing	Australia (Victoria)	Netherlands
Students are mandated to use technology in some or all high-stakes mathematics assessments	Norway

Students can choose to use technology in some or all high-stakes mathematics assessments	France	Hong Kong
		Ireland
		Israel
Students are not allowed to use technology in any high-stakes mathematics assessment	Slovakia	England
	Wales	Germany
		Italy
		Scotland
		Taiwan
		Turkey

Some countries are in the process of reviewing the role and use of technology in this educational phase. For example, in Ireland, the forthcoming introduction of an element of classroom-based assessment in mathematics during the “junior cycle” is expected to stipulate the use of digital technology – especially for statistical investigations. The influence of “big data” in wider society seems to be affecting attitudes to technology use in mathematics education as the need to develop students’ mathematical and statistical thinking through more open exploration and modeling of large data sets gains importance.

Technology Use in Upper Secondary Mathematics Education

Unsurprisingly, most policy guidance on technology use with respect to the curriculum and its

Mathematics Education and Technology,
Table 3 Technology use in pre-university mathematics education (14–19 years)

	Technology use is mandated in the national/ regional curriculum	Technology use is optional in the mathematics curriculum

	Wales	Italy
		Scotland
Technology use is not permitted in assessments		Taiwan
		Turkey

assessment is visible in the upper secondary phase, which coincides with the age range of the students who participated in the OECD survey.

The distribution of countries is shown in Table 3.

At this educational phase, several countries’ curricula refer explicitly to the (mathematical) affordances of the technologies that students should use. For example, the Welsh curriculum states:

At Advanced level, calculators must include the following features:

- An iterative function;
- The ability to compute summary statistics and access probabilities from standard statistical distributions.
- And they must not, for example, be designed or adapted to offer
 - Symbolic algebra manipulation;
 - Symbolic differentiation or integration

(Welsh Joint Education Committee 2017, p. 39)

Alternatively, other countries’ curricula offer a set of mathematical-technical competencies that students should acquire. For example, in Norway, students are expected to be enabled to: “perform,

describe and provide rationale for geometric constructions using a compass and ruler and dynamic geometry programs” in geometry; and “prepare functions that describe numerical relationships and practical situations, on paper and digitally, describe and interpret them and convert between various representations of functions, such as graphs, tables, formulas and text”. <https://www.udir.no/kl06/MAT1-04/Hele/Kompetansemaal/competence-aims-after-year-10?lplang=http://data.udir.no/kl06/eng>

In Victoria, Australia, where technology use in pre-university mathematics education has been mandatory since 2009, high-stakes assessments only occur in upper secondary mathematics, where the scores on examinations contribute to a score used for university entrance for many courses. The mathematical methods course incorporates the use of computer algebra system (CAS) technology, which is also required in the examination.

This contrasts with the consistent approach in Germany states where digital tools are mandated in the curriculum, with most schools choosing to use graphics calculators (with and without CAS functionality). The “Abitur” forms the final qualification, which involves a project element that can include the use of (CAS or non-CAS) technology within tasks that have been approved by the German “Institute for Educational Quality Improvement.” The German and Australian experiences have influenced the trajectory of curriculum and assessment in England (Button 2013).

Teacher Preparation and Support for Teaching Mathematics with Technology

There is wide variance in the countries’ policy and practice concerning the preparation of teachers to use technology within mathematics teaching. For example, in Australia, there is an expectation that graduate teachers can use ICT in their teaching (as prescribed in the teaching standards: <https://www.aitsl.edu.au/teach/standard>). The implication is that initial teacher training would prepare pre-service teachers to meet these standards. However, although there is no national

policy about the technologies used in mathematics specifically, taking the standards and curriculum together suggest that pre-service teachers do learn about mathematics specific technologies, as well as general technologies.

In Ireland, where the initial teacher education curriculum is not prescribed at a national level, there is an expectation (rather than a policy) that pre-service teachers will be introduced to appropriate mathematical technology. This picture is replicated in several other countries (i.e., England, Israel, Scotland). A number of countries report compulsory or elective courses within initial teacher education programs that are specifically focused on technology use in mathematics education (France, Portugal, Turkey).

For in-service teachers, again the picture is varied. Few countries report state-funded professional development (PD) initiatives in this respect, with most indicating that it would be the choice of the teacher to focus on mathematical (as opposed to generic) technologies. (i.e., England, France, Germany, Netherlands, Norway, Slovakia). In some cases, the PD opportunity is offered through local or regional networks, resulting in a varied picture of uptake, and therefore impact. Alternatively, government-funded initiatives led by university-based mathematics education teachers/researchers, such as the “m@t.abel” project in Italy (<http://www.scuolavalore.indire.it/superguida/matabel/>), have involved large numbers of teachers in focused PD.

Massive open online courses (MOOCs) are an emerging phenomenon for teacher PD, with colleagues in France, Italy (<http://www.difima.unito.it/mooc/>), and Norway all reporting their development, alongside some early evaluations (Panero et al. 2017; Taranto et al. 2017). A significant international community that has evolved from the GeoGebra software user group has now established formal PD programs in many countries (Italy, Hong Kong).

A number of studies are identifying the design principles for, and impact of, larger-scale PD programs for mathematics teachers, exploring the role of PD “multipliers” (Barzel and Biehler 2017) and online PD models (Clark-Wilson and Hoyles 2017).

Concluding Comments

Very few of the countries reporting for this review indicate any large-scale evaluation of the impacts of classroom use of mathematical technologies on students’ educational outcomes. Where evaluations have occurred, these were mostly smaller-scale studies of particular technology interventions (Wang 2011). Norway and Germany seem most advanced in this respect, conducting annual surveys of technology that reveal patterns of use. However, the most recent German report reveals that current teaching in science, technology, engineering, and mathematics was not bringing about the desired societal impacts relating to high-level technological skills (https://www.telekom-stiftung.de/sites/default/files/files/media/publications/Schule_Digital_2017_Web.pdf).

Regarding the wider use of technology, a large-scale study in Taiwan adapted a set of teacher technology integration performance standards (developed by the International Society of Technology in Education) to evaluate teachers’ technology integration proficiency. This study revealed six scales for teachers’ technology integration, including (1) teaching preparation and information gathering; (2) instructional material and hardware problem-solving; (3) management, communication, and sharing; (4) planning, instruction, and evaluation; and (5) professional development and self-study. Factor analysis revealed that teachers who had experienced more professional development scored higher (Hsu 2010).

As previously mentioned, the societal interest in “big data” is catalyzing curriculum developments with respect to increased use of technology in mathematical tasks that require statistical hypotheses, analyses, and modeling. In England and Ireland, technology is becoming mandated as part of classroom-based tasks and/or high-stakes assessment in this respect.

But a number of key challenges remain. The discussion about digital tools is often driven by the technical aspects of the hardware, rather than the deeper consideration of the (desirable) mathematical affordances to improve students’ engagement and participation in mathematics. This is

reflected in the presentation of curriculum policy guidance that emphasize the students' attributes in terms of their mathematical activity with the technology. Herein lies the biggest challenge. For teachers who have not been inducted into mathematics with technology, significant PD is required to enable them to rethink their own mathematics, alongside the pedagogies that accompany this.

This final comment sums up this issue and highlights the importance that the curriculum and assessment policy developments are underpinned by clear and wide communications of the vision concerning technology use in mathematics – and accompanying professional development opportunities for teachers:

Last summer (2017) Grade 13 students (19-years-of-age) in the scientific high schools were suddenly allowed to use graphical calculators in the National examination of grade 13. This new permission was given in spring 2017, unfortunately without any prior indication or support for teachers. This has caused some stressful situations for these students' teachers because they did not expect such a decision by the Ministry. [Questionnaire respondent]

Methodological Quality of Educational Technology Meta-analyses

Rana M. Tamim¹, Eugene F. Borokhovski² and Robert M. Bernard³

¹Zayed University, Dubai, UAE

²Centre for the Study of Learning and Performance (CSLP), Concordia University, Montreal, QC, Canada

³Department of Education, Centre for the Study of Learning and Performance (CSLP), Concordia University, Montreal, QC, Canada

Introduction

Scientists have known for centuries that a single study will not resolve a major issue. Indeed, a small sample study will not even resolve a minor issue. Thus, the foundation of a science is the culmination of knowledge from the results of many studies. (Hunter et al. 1982, p. 10)

Gene Glass's meta-analytic work in psychotherapy and on class size in education marked the beginning of a new era in systematic reviews (Glass 1976; Glass and Smith 1979). Despite the initial objections of some skeptics (e.g., Eysenck 1978, 1995; Gallo 1978; Presby 1978), meta-analysis (M-A), as a methodology of quantitative synthesis, has continued to grow exponentially and has become the most reliable source of comprehensive summaries of quantitative research in

a wide variety of fields (Glass 2016; Shadish and Lecy 2015).

However, like any other form of research, M-As can be biased in a number of ways (e.g., Abrami et al. 1988; Bernard et al. 2014a; Benard 2014; Cooper 2016; Polanin et al. 2016) and as a result possibly misrepresent the state of a research literature. Thus, attention should be paid to identifying sources of bias in M-As similar to that given to evaluating the quality of primary research (e.g., Valentine and Cooper 2008).

Narrative reviews and vote-counts are insufficient for achieving the degree of precision and comprehensiveness that M-A can. They are neither scientifically sound (Kline 2004) nor adequate in extracting information from the vast body of literature, organizing it, analyzing it, and presenting it (Glass 1976). They do not account for different sample sizes and the varying strength of results in different studies, they are not statistically powerful, and they do not address the size of the effect in a given study (Abrami et al. 1988; Hunt 1997). Furthermore, they rely heavily on statistical test outcomes, namely the p value, which is subject to all the null hypothesis testing limitations emphasized by many researchers including Meehl (1967), Cohen (1990), and Glass (1976). Finally, they are highly subjective (Bernard and Naidu 1990; Slavin 1984) and most of them are restricted to published research studies which includes the overestimation bias entailed with that (Kline 2004). As such, and while both approaches could be used with the methodology of systematic review (Cooper 2010), their limitations at the synthesis stage render them vulnerable to bias and misinterpretation.

Many general descriptions of M-A (e.g., Bernard and Naidu 1990; Card 2012; Cooper 2016; Cooper et al. 2009; Hunt 1997; Hunter and Schmidt 2014; Lipsey and Wilson 2001) address specific aspects of M-A conduct and reporting. Some works focus more on statistical analysis (e.g., Borenstein et al. 2009; Hedges and Olkin 1985; Pigott 2012), while others address specific issues of the methodology, such as acquiring literature (e.g., Hammerström et al. 2010), controlling publication bias (e.g., Polanin et al. 2016; Rothstein et al. 2005), and

addressing sample dependency questions (e.g., Scammacca et al. 2014). Furthermore, a number of associations have been formally established for the purpose of supporting systematic reviews in general and meta-analyses in particular (Bernard et al. 2004). Examples include the What Works Clearing House, the Cochrane Collaboration, and the Campbell Collaboration.

A general Google Scholar search on the 23rd of January 2018 for the term *meta-analysis* with no restrictions returned more than 3,500,000 hits in various fields of study. This is a solid indication that M-A has become a widely accepted approach for research synthesis in a variety of disciplines. A more education-focused search of the ERIC database on the same date resulted in the return of 5912 documents. This is a substantive (more than five times) increase from the 1100 documents that were located through the same ERIC search in 2009 (Tamim 2009). Such a burgeoning literature suggests that, in principle, this approach to research synthesis will only become more ubiquitous.

However, there are often disconnects between the methodological literature (i.e., what should be done) and the methodological practices that populate the research literature (i.e., what is actually being done). It comes down to this: when several M-As disagree, which results should be trusted more, and which should be interpreted with caution, or even rejected outright, because they could be severely biased? This very question is at the heart of this article: can an instrument be developed to reliably evaluate the methodological quality of M-As in the social sciences to reveal their areas of strength and weakness?

Several notable attempts to develop instruments to evaluate methodological quality of M-As come from the health sciences and allied fields (e.g., Higgins et al. 2013, Moher et al. 1999 – QUOROM; Schlosser et al. 2007 – EVIDAAC Systematic Review Scale; Shea et al. 2007 – AMSTAR). All of these instruments use a checklist and rating scale approach and have been tested with various M-As (e.g., AMSTAR was applied to nursing interventions by Seo and Kim in (2012). In the social sciences, however, there has been less activity devoted to developing a methodologically

sound and user-friendly tool that may be employed by producers, reviewers, and consumers of M-As. Below are some previous notable attempts.

1. Abrami et al. (1988) explored implementation problems in M-As by comparing six quantitative reviews from the literature of student ratings of instructional effectiveness;
2. Steiner et al. (1991) produced a methodology checklist for M-A and conducted a review of 35 published M-As in the areas of organizational behavior and human resources;
3. Torgerson (2007) reviewed and assessed the methodological quality of M-As addressing literacy learning in English;
4. Tamim (2009) conducted a second-order M-A of 25 M-As in the literature of educational technology, and as part of the method, evaluated these studies for their methodological quality;
5. Ahn et al. (2012) published a generalized assessment structure developed and used to evaluate M-As that had appeared in the *Review of Educational Research* between 1986 and 2013; and
6. Valentine et al. (2010) examined the quality of M-As in the after-school programs literature using a procedure that they developed.

However, unlike the health sciences, currently no specific and generally accepted approach has been designed and utilized for the evaluation of the methodological quality of M-As in the social sciences. While meta-analysts in the social sciences could make use of some of the tools from the health sciences, there are enough differences in the literatures to warrant a dedicated instrument. Most notably, there is the conceptual difference in the research paradigms in both areas of study with varying implications for practice. Primary research studies in the medical field are generally characterized by the clarity and focus of the research question and their high quality with regards to experimental research design (i.e. randomized control trials), and validity and reliability of outcome measures that are also used more consistently across individual studies. In contrast, primary research studies in social sciences generally address broader questions with limited

applicability of true experimental designs while employing a multitude of assessment tools of varying psychometric quality. Implications of that difference affect various aspects of M-A implementation, among which probably the most important one is selection of a proper analytical model (i.e., fixed versus random) for the effect size aggregation.

The current approach discussed here follows from the work of Tamim (2009) and is an unfolding attempt to design and develop a reliable instrument to evaluate the quality of reports of M-As around social science questions in general and education in particular, including the assessment of potential sources of bias in the different stages of the process. The particular objective is for the instrument to assist researchers, policy makers, journal reviewers, and graduate students in evaluating the methodological quality of M-As in their respective fields of interest.

Bias in Meta-Analysis

Benard (2014) defines bias in M-A as intentional or unintentional systematic inaccuracy in data due to characteristics of the processes employed in its collection, analysis, and interpretation that might affect a consumer's understanding of the review. It is understood and accepted that no methodology is completely immune to bias, and in many cases, especially in M-A, bias emanates from practice, not from conception. Considering that M-As are population studies that intend to evaluate the state of an entire collection of related primary research, the consequences of bias are much more detrimental than in individual primary research studies. Furthermore, this concern is exacerbated by the fact that, from a procedural perspective, a M-A entails a number of judgment calls that might have a considerable impact on its validity (Guzzo et al. 1987; Cooper 2017).

Particularly speaking, bias can reside in any of Cooper's (2017) steps for conducting a M-A, namely: formulating the problem; searching the literature; gathering information from studies; evaluating quality of studies; analyzing and integrating research outcomes; interpreting evidence; and

presenting results. However, the authors stress that not all steps of a M-A are equally vulnerable and argue that the most crucial types of bias are:

1. Publication bias which is related to Cooper's literature search step
2. Out-of-range effect sizes which is related to Cooper's gathering information step
3. Poorly designed primary studies which is related to Cooper's evaluating quality of studies step
4. Choice of the appropriate analytical model and overly leveraged effect sizes (which relates to Cooper's analyzing and integrating research outcomes step)
5. Confounded moderator variables which is related mostly to Cooper's interpreting evidence step

A brief overview of the listed potential sources of bias are given in Table 1. For a detailed overview and means of detecting bias in a M-A and correcting for it, check Bernard et al. (2014a) and Tamim et al. (under review).

Methodological Quality of Meta-Analyses

Considering that M-A was introduced about four decades ago and has since been established as an extremely powerful and valuable methodology for research synthesis, but not a straightforward (quite complex and sophisticated) one, questions about its methodological quality have become more pressing. For example, some researchers have long argued that the effect size offered by M-A may have "mischievous" outcomes especially with novice readers who may take the apparent "objectivity," "precision," and "scientism" as a seal of credibility (Cook and Leviton 1980). In a counter argument, Cooper and Arkin (1981) stress that there is nothing "mischievous" in the method itself, rather it may become so in the hands of some researchers due to "intention" or "ignorance," which is applicable with any innovative methodology. This is only heightened by the fact that many researchers have repeatedly

stressed that the main concern about the quality of meta-analytic findings is not related to the theoretical construct of the M-A, but rather to the quality of implementation by different researchers (e.g., Abrami et al. 1988; Benard 2014; Slavin 1984). The upcoming section describes the design, development, and verification process for a recently-developed approach, the *MMRQG*, as a generic evaluation tool to be used in the social sciences. That being said, the verification process for this development specifically used the educational technology literature for three major reasons, namely:

1. the original objective for the development of the first draft of the *MMRQG*;
2. the team's extensive experience in the field; and
3. the availability of a substantive number of published M-As in the area.

An important caveat to the use of the *MMRQG* instrument is that it applies to publicly available documents that report on various aspects of implementation of the methodology of M-A, not to actual review conduct (unless it is used by a novice researcher to guide the review). Hence, readers/assessors can only rely on what is explicitly reported by the authors of a M-A under consideration.

Development of the Meta-Analysis Methodological Reporting Quality Guide (MMRQG)

The Origin

The impetus for this project emerged from the development of an instrument originally designed by the first study by Tamim (2009), to help judge the quality of M-As that were to be included in a second-order M-A of the literature of technology integration in education. The instrument included 14 different items that addressed the comprehensiveness of a M-A (seven items) and its rigor (seven items). Items addressing comprehensiveness were: (a) literature covered; (b) search strategy; (c) resources used; (d) number of databases

Methodological Quality of Educational Technology Meta-analyses, Table 1 Overview of major sources of bias in M-A

Bias	Overview
Publication bias	According to Rothstein et al. (2005), “publication bias is the term for what occurs whenever the research that appears in the published literature is systematically unrepresentative of the population of completed studies” (p. 1). There is evidence that this bias is more likely due to the choice by journal editors to publish studies that “demonstrate an effect” as contrasted with studies that do not or that demonstrate negative results (Song et al. 2010). When appraising a review, readers should determine whether the authors have made serious attempts to locate and review unpublished studies, including conference proceedings, unpublished theses, dissertations, and other, so-called “grey” literature
Out-of-range effect sizes	The synonymous terms “out-of-range-effect sizes” and “outliers” are obviously relative since what is an overly large effect size in one study can be within range and not an outlier in another study. The effect that outliers have on a M-A depends on several characteristics of the effect size and the overall distribution of effect sizes under consideration. Effect sizes derived from primary studies with unusually large sample sizes, even if the effect sizes are not particularly large, can have a biasing effect on the weighted average, especially under the fixed effect model. Methodologically sound M-As necessarily pay attention to a possibility of bias introduction due to out-of-range effect sizes
Poorly designed primary studies	Methodological quality of primary studies, and the potential biasing effect of not addressing threats to internal, external, construct, and statistical validity, have been discussed extensively (Valentine and Cooper 2008). In conducting a M-A, there are several strategies for dealing with methodological study quality which range from being highly selective in the inclusion criteria to less selectivity coupled with various statistical adjustments (Abrami and Bernard 2012). Each of these methods has pros and cons that make it either more or less effective in controlling for methodological quality of studies included in a M-A; however, addressing this potential source of bias is of high relevance when appraising a M-A
Choice of the appropriate analytical model and overly leveraged effect sizes	Hedges and Olkin (1985) and Borenstein et al. (2009) describe two approaches to the synthesis phase of a M-A based on the purpose of the review and the nature and scope of studies that are likely to populate it. If the goal of the analysis is to find a single fixed weighted average effect size, studies must be judged to be essentially alike in terms of research questions, interventions, samples, settings, measures, etc., and if all studies in the population are available, the fixed effect model of synthesis should be used On the other hand, if studies are judged to be sufficiently different from one another in any or all of the above-mentioned characteristics so that a single weighted average does not seem to apply, the random effects model is more appropriate. Moderator analysis is typically conducted using either the mixed-effect <i>ANOVA</i>-analogue or the “method of moments” approach to meta-regression. Appropriate selection of the analytical model reduces the likelihood of bias in a given M-A
Confounded moderator variables	Confounded moderator variables represent one of the biggest challenges in a M-A. A meta-analyst typically deals with descriptions of moderator variables that may be confounded with each other. This makes the interpretation of the findings more challenging than in primary studies where the researcher has more control over the variables under investigation There is a potentially more serious issue of confounding that results from the inclusion of various research designs (e.g. Lipsey 2003). The most extreme difference in effect size might be observed when weak pre-experimental and higher quality designs are included in the same M-A. Consumers of M-A should address interpretations of findings of such reviews with caution

searched; (e) inclusion/exclusion criteria; (f) quality of included research; and (g) time between the publication date of the latest included study and the publication date of the M-A. Rigor-related items were: (a) article review; (b) effect-size extraction; (c) codebook; (d) study feature extraction; (e) independence of data; (f) standard error calculation; and (g) weighting by number of comparisons.

At that time, 38 M-As of varying quality were identified in the educational technology literature. From these, 25 M-As containing no more than 25% overlap among primary studies that were included in all M-As were admitted to the second-order M-A. That study found a significant weighted average effect size of $\bar{g} = 0.35$, $k = 25$, $p < 0.05$, between the treatment group where technology was present in classrooms versus the control condition where technology was absent. The methodological quality instrument allowed for the classification of included M-As into three categories: low quality ($k = 8$), medium quality ($k = 7$), and high quality ($k = 10$). Moderator variable analysis using the mixed model revealed that the three categories could not be differentiated on the basis of effect size ($p = 0.23$). However, there was an indication of an inversely related trend whereby lower quality M-As produced higher weighted averages ($\bar{g} = 0.42$), medium quality M-As produced lower ones ($\bar{g} = 0.35$), and higher quality M-As yielded the lowest average weighted effect sizes ($\bar{g} = 0.31$). For a more detailed overview about second-order M-A, kindly refer to the article (See ► [“Promises and Prospects of Educational Technology, Evidence from Systematic Reviews and Meta-Analyses”](#)) (second chapter by Authors).

Refinement

The findings from the initial application of the tool within the context of the second-order meta-analysis strongly suggested the potential merit of investing rigorous efforts into the issue of methodological quality of a M-A and its adequate assessment. As such, the decision was to move forward with further refinement of the tool. In

addition to the comprehensiveness and rigor items, and in order to address issues pertinent to conceptual clarity, two items were added, namely: (a) clarity of the experimental group definition; and (b) clarity of the control group definition. The 16-item instrument was used for the data analysis and findings reported in the second-order M-A of educational technology literature published in the *Review of Educational Research* (Tamim et al. 2011).

In 2014, the authors developed an advanced form of the instrument and pilot tested it. The number of items was increased to more closely match Cooper's seven steps for conducting a systematic review or M-A. Considering that a clear understanding of each item is needed for the tool to be usable, more elaborate descriptions of the items were devised and included in the new version. At that point, the instrument included 26 items that fell in seven categories, namely: (a) problem statement (6 items); (b) literature search (4 items); (c) procedural aspects of effect size extraction and study feature coding (2 items); (d) quality of studies (5 items); (e) synthesis of effect sizes (3 items); (f) interpretation of evidence (2 items); and (g) presentation of results (4 items). For the purpose of the pilot tests, two expert members of the research team evaluated the M-As in the areas of distance education (Bernard et al. 2014b) and technology integration (Bernard et al. 2014a). Both evaluators had previously been involved in every stage of developing and producing multiple M-As and had published M-As in a variety of venues.

Pilot Testing

The instrument was pilot tested with 15 M-As in the distance education literature, ranging in publication dates from year 2000 to 2014 (Bernard et al. 2014a). Two experienced coders used the instrument items to evaluate the meta-analytical procedure for each of the included M-As. The respective frequencies of positive and negative characteristics (not yet numeric values of rating per item) were used to assess the state of the literature. Findings indicated that methodological difficulties, as presented in Table 2, centered

Methodological Quality of Educational Technology Meta-analyses, Table 2 Study characteristic (seven-step review procedure) ratings across 15 M-As of distance education

Scale items	Problem statement (6 items)	Literature search (4 items)	ESs and study features (2 items)	Quality of studies (5 items)	Synthesizing effect sizes (3 items)	Interpreting evidence (2 items)	Presenting results (4 items)
Positive	15	9	14	9	5	14	13
Negative	0	6	1	6	10	1	2

Methodological Quality of Educational Technology Meta-analyses, Table 3 Study characteristic (six steps) ratings across 13 M-As of technology integration in education

Scale items	Problem statement (6 items)	Literature search (4 items)	ESs and study features (2 items)	Quality of studies (5 items)	Synthesizing effect sizes (3 items)	Interpreting evidence (2 items)	Presenting results (4 items)
Positive	13	10	8	6	9	11	N/A
Negative	0	3	5	7	4	2	N/A

around three major areas: literature search (i.e., publication bias); the quality of included studies (i.e., the inclusion of pre-experimental research); and synthesis of effect sizes (i.e., selecting the wrong/inadequate analytical model).

Based on the first pilot test, it was noted that the items included in the “presentation of results” category were realistically subsumed by or addressed in the other items/categories. As such, a subsequent revision of the instrument was performed resulting in the reduction in number of items to 22, addressing all the previous categories except the “presentation of results.”

The instrument was then subjected to a second pilot test with 13 M-As in the literature of technology integration in higher education ranging from the year 2000 to 2014 (Bernard et al. 2014a). The resulting category frequencies in Table 3 indicate adequate quality of M-A implementation with respect to searching the literature. As for the categories of extracting effect sizes and coding study features, the frequencies reflected the varying methodological quality of the M-As. Finally, and similar to the previous pilot study, potential bias vulnerability was detected with respect to synthesizing effect sizes and the inclusion of questionable-quality primary studies.

The Meta-Analysis Methodological Reporting Quality Guide (MMRQG)

As an outcome of the design, development, and pilot testing process, the final form of the *MMRQG* includes 22 items, as presented in Table 4. The items are coupled with brief descriptions that allow users to score each aspect of a M-A to reflect whether and to what extent it conforms to the rigorous standards of meta-analytical research. For every item, a three-level qualitative characterization (based on the information available in the respective reports) was used as follows: (1) yes (requirements for proper meta-analytical procedures/decisions at this stage are fully met); (2) somewhat (requirements are partly met); and (3) no/not reported (requirements are not met or the corresponding information is missing in the M-A report). Some of the items could apply equally to any form of the systematic reviews, whereas others are unique to M-As, as they relate to various aspects of effect size extraction and aggregation.

Verification of the *MMRQG*

As noted earlier, for verification of the *MMRQG*, the field of technology integration in education

22	Appropriate interpretation

was mainly selected because many individual M-As in this area have been produced over decades (i.e., enabling an investigation of a larger sample of reviews) and because of the team’s experience with this body of the literature. Available to the team were the initial set of 38 M-As reviewed and synthesized in Tamim et al. (2011) dating to the end of 2008. In addition, search updates (using the same strategy and resources outlined in the original second-order M-A) were performed to locate relevant M-As published since 2008. As a result, twelve M-As were added to the collection through the review and selection process carried out by the first two authors. The same two reviewers then independently assessed a sample of 25 M-As (i.e., 50% of the available data set), including all the most recent ones (i.e., published after 2010). Each question on the *MMRQG*, together encompassing all aspects of methodological quality, was assessed using the numeric values described above that reflected the degree to which the respective aspects of each M-A conformed to the “best practices”. Disagreements were marked, discussed, and resolved. Inter-rater agreement rate for initial independent coding was 93.5% or Cohen’s $\kappa = 0.87$.

In addition to establishing inter-rater reliability between the two main expert coders, two relatively inexperienced coders were asked to participate in coding a sample M-As from the complete collection of 50. These coders were graduate students (team research assistants) who had participated in coding moderator variables in some of the team’s previous studies, but never had been involved in the planning and/or execution of a complete M-A. They were given a general introduction to the *MMRQG* and then independently coded ten randomly selected M-As. They subsequently met to discuss any discrepancies and reached agreement on a single combined code that was compared to

that of the expert reviewers. Table 5 reports the results of this coding exercise with all coding statistics (for either pair of comparisons) being reasonable, despite some differences between novice and expert coders.

Simple arithmetical sums of all codes across 22 *MMRQG* items composed the total index of methodological quality with a theoretical range from 0 (all items coded as ‘No’) to 44 (all items coded ‘Yes’). One could reasonably suggest differential weights of individual items (e.g., based on previously discusses major sources of potential bias), but for the purpose of the validation study the “one point for one item” scoring system was used. The resulting scale appeared to be a reasonable approximation of a continuous variable, and as such, was employed in the subsequent meta-regression analysis as an integer predictor for the magnitude of the respective effect size. Additionally, each individual item was subjected to the moderator variable analyses (ANOVA-analogue) as a categorical variable with three (rather descriptive) levels broadly reflecting Low, Moderate, and High methodological quality of a M-A under review.

In the analyses, effect sizes extracted from the reviewed M-As were used, as they were reported and then converted (when required) to the common metric of Hedges’s g . One effect size representing the r -family was converted from a correlation coefficient into Cohen’s d (Borenstein et al. 2009), and then into Hedges’s g . Because in a M-A the unit of analysis is an individual primary study (or, more precisely, an independent extracted effect size), standard error was estimated based on a number of comparisons reported in each M-A under review as follows:

$$SE_{g^{++}} = \sqrt{\frac{1}{k_E} + \frac{1}{k_C} + \frac{g^2}{2(k_E+k_C)}} \left(1 - \frac{3}{4(k_E+k_C)-9}\right)$$

Note that as each comparison requires an experimental and a control group, the reported

Methodological Quality of Educational Technology Meta-analyses, Table 5 Inter-rater reliabilities for three combinations of 10 randomly selected meta-analyses

Reliability metric	Independent decision: expert coder vs. expert coder	Independent decision: novice coder vs. novice coder	Joint decision: expert coders vs. novice coders
% Agreement	97.73%	89.32%	81.51%
Cohen’s κ	0.95	0.79	0.63

number of cases (k) in the formula above was actually doubled (i.e., $k_E + k_C$, where E and C stand for experimental and control condition respectively and k_E necessarily equals k_C).

In total, 50 M-As were located, reviewed, and analyzed. One outlier was detected and removed because of its extreme effect on the data set ($\bar{g} = 3.84$). This outlier originated in a M-A (Yeşilyurt 2010) that did not use standardized effect sizes (i.e., the mean difference was not divided by a standard deviation). As a result, the final number of M-As in the collection was 49.

Quantitative Synthesis of 49 Meta-Analyses

One of the first steps was to examine the meta-analytic results of the entire collection of reviews, independently of their quality ratings. These are the findings that would derive from a second-order M-A.

Table 6 presents summary statistics related to the final collection: the weighted average effect size ($\bar{g}^+$, the average of averages); the number of effect sizes (K , the number of average effect sizes); the standard error (SE , based on $k_E + k_C$); and the lower and upper limits of the 95th confidence interval, resulting from both random and fixed analytical models.

The overall average effect size is statistically significant ($p < 0.001$) for both models. The unweighted average ($\bar{g}^+$) is slightly higher at 0.397 with a standard deviation of 0.228. The heterogeneity statistics based on the fixed effect model indicate that the collection is homogeneous, with an I^2 -value of 9.09%. Therefore, there are no studies that should be removed or reduced in magnitude. These findings compare favorably to the

results achieved in the initial second-order M-A of 25 M-As (Tamim et al. 2011). However, the funnel plot indicated the potential for publication bias. Duval and Tweedie’s trim and fill routine (Duval and Tweedie 2000) indicates that an additional 14 studies would have to be found on the negative side of the distribution to achieve symmetry. This is not considered a particular problem in this study since it was not trying to represent the population values in the results, but to appraise possible connections between the M-A methodological quality and its respective effect size. Nevertheless, it is an indirect indication that the publication bias of primary research may culminate with published M-As, calling for additional attention to assessment of their methodological quality in order to better inform readers’ decisions of how adequately any given M-A represents the state of its corresponding field of research.

Examining the MMRQG

As noted earlier, each M-A was rated by two expert reviewers on each of the 22 items in the MMRQG. Disagreements were discussed, and a value for each item was established by consensus between the reviewers. Table 7 shows the mean and standard deviation for each item.

Factor Analysis

The first step in investigating the characteristics of the MMRQG was to conduct factor analysis to determine if clusters of items formed a discernable underlying structure. Principal components analysis was conducted and Varimax with Kaiser Normalization was used to rotate the factor matrix. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was 0.714, a modest but adequate

Methodological Quality of Educational Technology Meta-analyses, Table 6 Overall weighted average effect size and heterogeneity statistics

value of the item by sample size ratio, and Bartlett's Test of Sphericity was significant ($\chi^2 = 597.57$, $df = 231$, $p = 0.000$), indicating the absence of an identity matrix (or the presence of underlying inter-correlations). The results converged in nine iterations. Seven factors with eigenvalues greater than 1.0 were extracted, accounting for 74.8% of the variance (Table 8 shows the results from the first three factors).

Factor 1, with an eigenvalue of 8.20, appears to relate to overall general concerns about the coherence of the analysis, the interpretation, the reporting, and description in the M-As. Factor 2 is a combination of general and technical issues, and Factor 3 has to do with review procedures, outlier identification, and the validity of included studies (e.g., research design). All 22 items were implicated in one or more of the seven factors extracted.

Factor Score Weighted Multiple Meta-Regression

Weighted multiple meta-regression was used to investigate the relationship between the factor structure described above and the empirical effect sizes derived from each study. To do this, factor scores generated from the factor analysis served as predictors in inverse variance weighted multiple meta-regression (method of moments). The dependent variable was *d*-type effect sizes from each study, transformed into Hedges's *g*. The results produced an *R* (multiple correlation) of 0.53 and an $R^2 = 0.28$, or 28% of variance accounted for in the

Methodological Quality of Educational Technology Meta-analyses, Table 9 Weighted multiple regression (weighted by factor scores) of seven factors on average effect size with Eigenvalues over 1.0

Factors	β	<i>SE</i>	Beta	<i>t</i> -value	Sig.

^aWhile not significant at $\alpha = 0.05$, it is considered close enough to bear further scrutiny

Methodological Quality of Educational Technology Meta-analyses,

Fig. 1 Scatterplot of the regression model of association between MMRQG scores and observed effect sizes

distribution of effect sizes. The *ANOVA* associated with the analysis was significant [$F(7, 41) = 2.28, p = 0.047$], indicating an overall relationship between the independent and dependent variables. Table 9 shows the results of the analysis of each factor. Factor 1 produced a significant relationship between factor scores and effect size and Factor 3 was marginally significant. The slope of the first three factors was negative, indicating that larger effect sizes were related to lower ratings of M-A methodological quality (and the inverse). Figure 1 shows these relationships, graphically.

Individual-Item Weighted Simple Meta-Regression

Of particular interest was the question of whether the methodological quality indicators of the M-As are related to the magnitude of their reported effect sizes. Table 10 shows the results of Factors 1 and 3 regressed on the average effect size with Hedges’s $\bar{g}$ as the outcome variable. Note that, while not significant in multiple meta-regression, Factor 3’s significance level of $p = 0.071$ was considered close enough to bear further scrutiny. Only the significant items within the two factors are

^aWhile this item is not significant in regression, it is included here because it is significant in *ANOVA*-analogue moderator analysis (See Table 10)

included in Table 10. Ratings of all seven items were inversely related to effect size, suggesting that higher ratings (i.e., better quality studies for these items) produce lower effect sizes (this finding was also indicated in the analysis of factor scores depicted in Table 9).

As an adjunct to these analyses and to provide a more explicit indication of the magnitude of each quality category, *ANOVA*-analogue mixed effect moderator variable analysis was applied to each item shown in Table 11, with high, moderate, and low forming three methodological quality categories. The advantage of these analyses is that they show the average weighted effect size in each rating category and the approximate difference between effect sizes. Q_{Between} was tested using the Chi Square distribution with $df = p - 1$.

In most cases, lower quality studies (Low or Moderate) tended to produce larger average effect

sizes than higher quality studies, as was indicated in the meta-regression analysis.

Reliability Analysis of the MMRQG

Scale analysis (i.e., Cronbach's α) was conducted on the set of 22 items and subsequent reductions, to determine if the instrument's reliability was affected by the removal of each item in turn. The results for alpha are shown in Table 12 along with the estimated random error variance for each collection. These analyses reveal that the reduction of items, based on factor analysis and meta-regression had minimal effect on the reliability estimates. All of these reliabilities are considered reasonable for a standardized instrument (Tavakol and Dennick 2011).

In order to further investigate the reliability of the *MMRQG*, a split-half analysis of the two major sections of the instrument was performed. Items

Methodological Quality of Educational Technology Meta-analyses, Table 11 ANOVA-analogue moderator variable analysis (mixed model) for each significant *MMRQG* item

Quality levels	K	$\bar{g}^+$	Lower 95th	Upper 95th	Q_{Between}
Factor 1					
Item 19. Overall analyses					
Low	9	0.55	0.32	0.79	
Moderate	33	0.37	0.31	0.43	
High	7	0.27	0.20	0.35	
Between groups, $df = 2$	6.81, $p = 0.03$				
Item 21. Reporting results					
Low	8	0.39	0.25	0.53	
Moderate	28	0.42	0.33	0.50	
High	13	0.29	0.22	0.36	
Between groups, $df = 2$	5.98, $p = 0.050$				
Item 20. Moderator variable analyses					
Low	14	0.45	0.32	0.58	
Moderate	28	0.38	0.32	0.45	
High	7	0.27	0.19	0.34	
Between groups, $df = 2$	7.88, $p = 0.02$				
Item 22. Interpretation of findings:					
Low	5	0.36	0.20	0.52	
Moderate	28	0.44	0.35	0.52	
High	16	0.29	0.22	0.35	
Between groups, $df = 1$	7.42, $p = 0.02$				
Item 4. Experimental group description:					
Low	9	0.47	0.29	0.65	
Moderate	24	0.40	0.32	0.48	
High	16	0.29	0.23	0.36	
Between groups, $df = 2$	6.44, $p = 0.04$				
Factor 3					
Item 18. Outlier analyses					
Low	35	0.40	0.33	0.47	
Moderate	6	0.38	0.20	0.55	
High	8	0.27	0.19	0.35	
Between groups, $df = 1$	6.41, $p = 0.04$				
Item 14. Validity of included studies					
Low	27	0.38	0.31	0.45	
Moderate	15	0.42	0.30	0.54	
High	7	0.27	0.19	0.35	
Between groups, $df = 2$	6.27, $p = 0.04$				

1 through 11 are items that can apply to any systematic review, whereby items 12 through 22 are items that address meta-analysis specifically. Average item values were generated across the 49 M-As and divided into blocks of eleven items each. The Pearson Product-Moment Correlation between the two halves of the instrument was $r = 0.79$,

$p < 0.0001$. The Spearman-Brown correction produced a correlation of $r = 0.88$. This result suggests that there is consistency across the two sections similar to the consistency that was found across the instrument as a whole, in spite of the fact that there is a significant difference between the averages of Section One and Section Two, with Section One

Methodological Quality of Educational Technology Meta-analyses, Table 12 Cronbach’s alpha for the original collection of 22 items and three reductions

Different collections of items	Cronbach’s alpha	Random error variance
Alpha for 22 items (entire instrument)	0.93	0.15
Alpha for 8 significant items (factors 1, 2 & 3)	0.89	0.21
Alpha for 7 items in factors 1 & 3	0.88	0.23
Alpha for 5 items (factor 1 only)	0.87	0.24

being significantly higher than Section Two ($t [48] = 6.09, p < 0.001; M_{1-11} = 1.02, M_{12-22} = 0.77$).

MMRQG and the Date of Study Publication

The final question that we asked was “According to the results of the *MMRQG*, how has the methodological quality of the 49 reviews from this literature changed from the 1980s until the present”? To answer this question, we performed correlational analysis between total score on the *MMRQG* and date of the study. It seems reasonable to suggest that the accumulation of conceptual and methodological literature, since Glass’s first introduction of the methodology in 1983, should have produced a noticeable increase in the quality of M-As. We found this assumption to be partly true in the literature that we reviewed. The correlation between the *MMRQG* ratings and date of publication was $r = 0.48$ ($p < 0.001, r^2 = 23\%$). Figure 2 shows this general increase in methodological quality over time. It might be noted that in the middle period, from about 1995 to about 2010, there are mixed results. However, in recent years there is a more uniformly positive result. When the results indicated above were more closely examined using one-way *ANOVA* with post hoc comparisons, the only significant difference was between the mean of the 1980s category ($\bar{X} = 13.0, K = 3$) and the most recent

period from 2010 to the present ($\bar{X} = 28.75, K = 8$). There is an incremental increase across the other three categories, but these are not significantly different from each other.

While these results are generally positive, it appears that there is still a need to educate aspiring meta-analysts in the best and most up-to-date information on the methodology. In addition, there is still, and likely always will be, a pressing need to teach graduate students how to conduct M-As that are complete, methodologically sound, and to the extent possible, free of bias.

Discussion

An iterative process, which spanned almost 10 years and included three revisions and two pilot tests, resulted in the production of a 22-item *MMRQG*. While the instrument itself was not the primary objective of the original project (Tamim 2009), the importance and relevance of such a tool to users, journal reviewers, graduate students, and producers of M-As in the social sciences, particularly in education, has become more evident with time and with the ongoing publication of M-As in a host of fields, and often multiple M-As produced around a given topic. As such, the main objective of the current project was to formalize and verify an instrument to eventually make it available to various audiences for the purposes of evaluating the methodological quality of M-As in the social sciences, particularly in education.

The final verification of the instrument involved expert rating of 49 M-As from the literature of educational technology – more specifically, the effects of the application of technology (in comparison with no technology) used in elementary through university education from 1985 through 2014. The results of the verification study of the *MMRQG* allows for several noteworthy conclusions to be drawn.

1. The instrument seems to have a dimensional structure that separates items into coherent clusters, particularly in regard to the highest loading groups of items. Factor 1 addresses overall general aspects relating to the relevance

Methodological Quality of Educational Technology Meta-analyses,

Fig. 2 Scatterplot of study date by *MMRQG* rating

and coherence of the analysis, and the interpretation and reporting in a M-A; Factor 2 relates to a combination of general and technical aspects; and Factor 3 has to do with review procedures, outlier identification, and the validity of included studies. In all, 12 out of the total of 22 items comprise these three factors and account for about 75% of the total item variance.

2. It is likely that low-quality M-As provide an overestimate of the average effect size. There is a strong negative relationship between the five items in Factor 1 and the average effect sizes reported in the 49 M-As. While remaining negative, this relationship is weaker in factors two and three. The negative sign indicates that higher effect sizes are related to lower quality rating on these items, a finding recently reported by Polanin et al. (2016) in regard to the relationship between publication bias and effect sizes of M-As.
3. More nuanced meta-regression and *ANOVA* analogue analysis at the item level significantly differentiated low-quality ratings from high-quality ratings, although this relationship,

particularly for moderate and low, was not always uniform across all items.

4. The scale estimate (Cronbach's α) of the instrument is generally high and does not diminish substantially as the instrument is gradually reduced from the original 22 items to a subset of five items that comprise Factor 1. The split-half reliability estimate of the two halves of the instrument (i.e., items 1–11 and 12–22) suggests that each subset is as reliable as the instrument as a whole. As an additional note, these results were achieved in spite of the minimal ratio of items to studies that would normally adversely affect all of these analyses, from factor analysis to reliability analysis.

In spite of the predictive validity that has been established for a subset of items, both parts of the instrument are considered to be equally important for judging the quality of a systematic review and M-A. In other words, it is considered to be insufficient to use only the items in Factors 1 through 3 to evaluate systematic reviews. The first 11 items address the early stages in conducting a systematic review of any type, while items 12–22

are mostly related to the technical and statistical aspect of quantitatively synthesizing effect sizes, i.e., more specific to M-A. Not surprisingly, it was primarily the second set of items that was significantly related to effect size, in a negative direction. There is no similar metric for assessing the predictive importance of the first 11 items, but it is known that quality ratings of these items are about the same for both halves. It is judged that a systematic review or a M-A that is deficient across either or both domains of items is potentially problematic. While the current findings do not suggest that average effect sizes from lower-quality M-As should be dismissed entirely, they do imply that these studies need to be interpreted more cautiously, especially when there are other higher-quality reviews of the issue that indicate different results.

In this verification, equal weight was given to each item. No a priori weighting was used in the coding, although empirical weights were applied in multiple meta-regression since the predictors of effect size were weighted in factor analysis (i.e., factor scores). While this examination of predictive validity is interesting and useful, it does not tell the whole story about the non-predictive items generally found in the first half of the instrument or their relative value for the purposes of this project. There tends to be a “feed-forward” effect in constructing a M-A. That is, decisions made in the early stages (e.g., establishing inclusion-exclusion criteria) can and do impinge on later stages. For instance, the decision to include only studies from peer-review journals (Item 10) can create bias that may only be detectable in publication bias analysis (Item 17), leading to potentially biased overall analyses (Item 19), reporting (Item 21) and interpretation (Item 22) of the M-A results. So, it would be incorrect to assume that the items in the second half of the instrument are more important than those in the first.

One of the limitations of the *MMRQG* development study is that it was conducted with one body of literature that may or may not be representative of all such collections in other domains. Therefore, other researchers are encouraged to conduct similar exercises for similar collections in other fields of study in the social sciences. Analogous results from other areas might suggest adaptations for special cases,

and future efforts might be able to develop conceptually-based differential weighting of the various *MMRQG* items.

In practical terms, the ratings of the *MMRQG* by two expert and two novice researchers in the evaluation process of 49 M-As addressing the impact of technology integration on student learning supports its applicability, at least, within the field of education. While both experts and novices may use this instrument, it is arguable that it would be most beneficial for mid-level evaluators of M-As, such as graduate students, researchers, and journal article/dissertation reviewers. It is understandable that this target audience may need a guide to the most salient aspects of a systematic review or M-A. Of particular relevance is the fact that, although interrater agreement analyses indicated a difference between novice coders and expert coders, all outcomes were statistically reasonable. This strongly suggests that the *MMRQG* is not out of the novice researcher's reach.

Considering the complexity of the statistical analysis procedures in a M-A, the *MMRQG* in its current form, particularly items 12–22, requires specialized knowledge for a user to derive the most benefit from it. Subsequently, the task of further refinement of the instrument for less informed audiences, especially graduate students, is under consideration.

In Conclusion

Four decades after its introduction in the 1970s as a quantitative review methodology, M-A has demonstrated its ability to overcome criticism and gain traction among researchers as a systematic approach for synthesizing quantitative research findings (Glass 2016). However, it has to be widely recognized, by producers and consumers alike, that M-As vary significantly in terms of current best practices and processes. The *MMRQG* provides a means of evaluating the quality of M-As that are already in the literature. As well, its structure can be used as a guide to producing new M-As. By far the best way to improve the practice of M-A is through training, experience and understanding, and use of the prolific methodological literature that has developed

since the 1970s. The same might be said about those who intend to evaluate M-As using designed instruments, including the *MMRQG*. The use of the *MMRQG* by meta-analysts, journal reviewers, and consumers of M-As, not only as an assessment tool, but also as a learning tool, is expected from results to date to have a positive impact on the methodological quality of M-As and further substantiate the validity and reliability of findings, as well as increase preparedness of broader audiences of researchers to meaningfully use and confidently produce better quality (i.e., more credible) M-As in the social sciences.

Introduction

Mobile computing serves as a learning technology that is ubiquitous in nature, highly portable, and endowed with multimedia capabilities that contribute significantly to a new dimension of learning content delivery to students. The results of numerous research studies that examined the contribution of mobile computing to the teaching and learning processes conclusively confirm that sophisticated digital mobile technology in its different forms serves as a vital and legitimate delivery platform for learning throughout the educational system. The introduction of digital mobile technology into the educational domain has contributed to the enhancement of instruction and learning at all levels of the educational system. Mobile devices add innovative educational features to teaching and learning that make the educational experience more motivating and exciting. These advances have prompted educators to increasingly utilize mobile devices to promote teaching and learning. Mobile devices transform the teacher-student relationship and lead to significantly interactive engagement between teachers and students in the educational process. Mobile computing and learning has changed the face of the traditional classroom and school and has led to an educational framework that is not necessarily bound by time or location but actively connects teachers and students in a digital framework. The sophisticated advancement of computing and communication technologies made over the past years in the parallel development of digital databases and the technological ability to deliver the knowledge stored in these databases through high-speed and reliable

Internet connections have laid the foundations for advanced technology-based learning paradigms that range from electronic learning (e-learning), distance learning (d-learning), and mobile learning (m-learning) to ubiquitous learning (u-learning) (following Katz 2014).

The technological platform that allows for mobile computing and learning is the internet which has become the main vehicle for the dissemination of up-to-date knowledge to all potential learners. Mobile devices connected to the Internet have become part and parcel of the teachers' and learners' daily educational experiences. Being ubiquitous, mobile learning is suitable for learning outside formal school settings and formal school timetables and can be conducted without limitations of time and location. Thus, the ubiquitous nature of mobile learning provides for a rich variety of teaching and learning alternatives that enhance both cognitive and affective domains so vital for significant educational processes. In addition, the growing use of mobile computing and learning in educational settings suggests that the classroom will increasingly be characterized using mobile computing in routine teaching and learning activities. This development will enhance the personalization and customization of learning for the individual learner with the individual teacher's role increasingly becoming one of a facilitator.

Technical Characteristics of Mobile Computing and Learning

Mobile computing and learning, a specific development of internet-based electronic learning, offers a rich and sophisticated technology-based learning environment that is especially characterized by innovation offered to the learner. Additionally, mobile learning has the characteristics of portability, convenience, and interactivity without strict requirements for time, environment, and location, so that students can learn at their leisure. It should be noted that the use of mobile learning provides enhanced technological possibilities of using small and lightweight handheld devices such as iPads, tablets, and smartphones

which include text, voice, still camera, video camera, paging, and geo-positioning capabilities. These tools provide a rich variety of technology-based delivery strategies that enhance student-centered learning. Desktop PC computers are constrained by their static location and are too heavy to be moved easily so that learners are compelled to work in the same place. Even regular laptop computers can be a little cumbersome and uncomfortable to use anytime and anywhere. By contrast, learning with a small handheld device is comfortable with little physical limitations because of size and technological potency. Specifically, flexible portability is the most distinctive feature which distinguishes handheld devices from other emerging technologies, and this factor makes other technologically enhanced attributes such as individuality and interactivity possible. Although tablets and iPads and even small-screen laptops are handheld devices suited to act as receivers of mobile learning, the handheld smartphone is the most prolific mobile learning device available and competently serves as the preferred effective, efficient, comfortable, and user-friendly receiver of mobile learning delivery. In addition, the sophistication of smartphones makes them highly prestigious from the psychosocial point of view and therefore the most preferred and desirable instruments of learning among young learners at school and university age (following Katz 2015a).

Pedagogical Characteristics Related to Mobile Computing and Learning

Mobile learning, which enhances students' learning experiences and offers them almost unlimited access to resources, is an effective platform for the delivery of learning content. Mobile learning contributes significantly towards a more comprehensive educational environment for learning. Learners feel that mobile learning is convenient and easy to use to access databases and knowledge and enhances autonomous learning activity. In addition, mobile computing and learning allows students to engage in problem-solving-based learning activities and to work on tasks

that are goal-oriented and open-ended. In addition, mobile learning empowers students to be actively involved in the learning process, thus allowing for potential improvement in the educational experience (Wang 2017).

Mobile learning particularly provides opportunities to learn through the medium of flexible delivery platforms. Recent studies (following Katz 2015a) have indicated the increasing effectiveness of the contribution of mobile learning delivery platforms to the enhancement of the learning process. These studies have indicated that the latest modes of mobile learning delivery are associated with improved quality of students' learning experiences and have emphasized that mobile learning is significantly more flexible and provides students with especially accessible content and sources. In addition, mobile learning is student-centered and promotes autonomous, creative, flexible, motivated, satisfying, and self-confident learning of students. Thus, learning via mobile delivery platforms is positively received by students and contributes to an enhancement of cognitive as well as affective variables that are vital for the enhancement of student performance in the educational process. In short, mobile learning delivery platforms afford ample and potentially effective opportunities to improve student learning at the school and university level.

Cognitive Variables and Mobile Computing and Learning

A number of research studies have indicated that cognitive performance such as achievement and the development of higher-order thinking skills of students is positively related to the use of mobile learning delivery platforms. As technology has developed, mobile learning is increasingly used in a number of areas of content and subject matter, but outstanding examples of mobile learning as an effective learning delivery platform may be found in the domains of language learning and the exact sciences.

Achievement and Mobile Computing and Learning

Mobile-assisted language learning (MALL) is fast developing as a common as well as legitimate learning delivery platform, and widespread research studies have indicated that mobile delivery of vocabulary has a more significant effect on students' vocabulary learning achievement than traditional instruction based on the use of dictionaries. There is solid research evidence that students who studied idioms via mobile delivery were more enthusiastic about their learning and attained higher scores on an achievement test than their counterparts who studied by traditional teaching methods. The above results are most common among students who studied English language vocabulary via mobile delivery to their smartphones and performed significantly better on English vocabulary achievement tests than students who received their vocabulary lessons by way of traditional face-to-face instruction. Additionally, research evidence has indicated that learning mathematics and the exact sciences via the medium of mobile learning delivery enhanced students' understanding of content matter and positively affected their achievement and learning outcomes (following Ituma 2011; Chandra and Watters 2012)

Higher-Order Thinking Skills and Mobile Computing and Learning

Researchers concur that mobile learning acts as a main support to extend and improve learners' capacities to engage in learner-centered, assessment-centered, and knowledge-centered practices that are the basis for the promotion of higher-order thinking skills. Furthermore, learning with mobile technology has clearly shown that the mobility and connectivity of technological tools enable students to become active participants in analytic thinking and evaluation processes rather than being passive receivers of learning content and information.

Mobile technologies offer a new field to explore in which learning opportunities are extensively distributed and shared, thereby increasing

the students' potential to adopt higher-order thinking strategies. Researchers generally agree that learners' positive attitudes toward the utilization of mobile computing can be a significant factor affecting pedagogical approaches to enhance higher-order thinking. Specific research studies have indicated the efficiency of using mobile computing devices as mediators that scaffold and enhance higher-order thinking skills (following Psycharis 2013).

Thus, increasingly more education-related mobile applications have been developed to promote students' overall learning and thinking processes that contribute to enhanced performance. Many mobile learning applications are designed to develop higher-order thinking as well as teacher-student interaction and inter-student collaboration that have been shown to facilitate as well as support higher-order thinking processes (following Katz 2014).

Affective Variables Related to Mobile Computing and Learning

Over and above the relationship between mobile learning and students' scholastic and academic achievement, research studies have been conducted to examine the relationship between mobile learning and students' affective attitudes that contribute to the enhancement of the learning process. Teacher and learner autonomy, teacher and learner creativity, teacher and learner flexibility, teacher and learner motivation, teacher and learner satisfaction, and teacher and learner self-efficacy (which includes teacher and learner technological self-confidence) are some of the major factors that have been found to be positively related to students' willingness to utilize mobile learning delivery platforms in the instructional and learning processes. Katz (2014) described the association of the above factors with mobile learning delivery platforms and the significance of these affective factors in facilitating student achievement and confirmed the results of the abovementioned studies that indicated that

students who attained higher levels of scholastic achievement and success in their studies held significantly more positive affective attitudes toward the utilization of mobile learning delivery platforms in their learning experiences. The following are descriptions of the major affective variables closely related to the effective utilization of mobile computing in the educational process:

Autonomy and Mobile Computing and Learning

Teacher and learner autonomy are significant factors that contribute to effective use of mobile learning. Results of numerous research studies have pinpointed the advantages of teacher and learner autonomy when utilizing mobile learning delivery platforms and have confirmed the relationship between teacher and learner autonomy and effective utilization of mobile technology in the teaching and learning processes. Some of the studies have suggested that teacher and learner autonomy are, in fact, a suggested prerequisite for efficient use of mobile learning in the educational process. Thus, autonomy characterizing both teachers and students can be considered as an important affective variable that serves as a prerequisite for effective and enhanced teaching and learning with mobile computing and learning (following Katz 2014, 2015b).

Creativity and Mobile Computing and Learning

Creative teachers and students are those who invariably indicate a willingness to try new things and use innovative educational approaches such as the harnessing of technology in general and particularly mobile computing, in the educational process. Teachers' creative use of mobile computing in their instructional practices enhances students' tendencies to be more creative and enthusiastic in their studies and facilitates their ability to acquire the creative skills necessary for success in problem-solving and applying knowledge. Current research studies have contended that the use of creative approaches by teachers affords students the opportunity to more

efficiently utilize mobile learning in the learning process. Thus, creativity exhibited by teachers and students can be considered a major affective variable that contributes to the efficiency of mobile computing and learning (following Hosseini 2014).

Flexibility and Mobile Computing and Learning

Research studies that examined the relationship between affective variables and the willingness of teachers and students to effectively utilize mobile computing in the educational process found that personality flexibility is a defining factor in teachers' and students' ability to more readily benefit from the use of mobile learning delivery platforms inside as well as outside of the classroom. In addition, research results have indicated (a) that teachers' flexibility and belief in innovation are major factors affecting the successful use of mobile-based instruction in their classrooms and (b) that students who demonstrate flexibility in their thinking and learning are highly disposed toward the use of mobile learning delivery platforms (following Katz 2014).

Thus, the flexibility variable is significantly related to teaching and learning via mobile computing applications as well as to the enhancement of students' positive engagement in the learning process.

Motivation and Mobile Computing and Learning

Consistent results of research conducted over the years since technology was introduced into teaching and learning processes on a mass scale have clearly indicated that in schools where sophisticated technology-based instructional packages were introduced into the school curriculum, motivation of teachers as well as of students has been enhanced. The use of mobile learning technology by teachers provides them as well as their students with instructional and learning opportunities that motivate them to better deal with the study material than traditional instructional strategies that do not utilize mobile technology. Both teachers and students involved in instruction and learning via the delivery of mobile educational packages have

shown higher levels of motivation than those who used other teaching and learning strategies. In addition, the teachers and students exposed to instructional strategies based on mobile computing perceived teacher-student readiness to interact in the classroom situation to be more positive and intense than in classrooms where teaching and learning did not include mobile-based strategies (following Katz 2015b).

From the abovementioned research results, it certainly appears that motivation is another centrally valuable affective variable that encourages both teachers and students to utilize mobile computing tools in their teaching and learning to promote efficient and positive cognitive and affective interaction in the educational process.

Satisfaction and Mobile Computing and Learning

One of the key affective variables that positively affects teacher and student performance is the satisfaction of both teachers and students with the introduction of mobile computing into the teaching and learning processes. When teachers and students utilize mobile delivery platforms in teaching and learning, the level of their satisfaction with the educational process increases as does student performance. Research studies that addressed the issue of teacher and learner satisfaction with the use of mobile technology in their teaching and learning found that teachers who utilize mobile learning delivery are more satisfied with their teaching and are better liked and respected by their students who are prepared to invest more in their learning inputs.

Additional research results confirmed that satisfaction with the use of mobile computing in the learning process significantly explains the enhancement of students' learning performance, mainly because the mobile-based learning environment specifically fosters student satisfaction with the learning process. The above evidence emphasizes the importance of satisfaction of both teachers and students in teaching and learning and the significant contribution of the use of mobile computing to satisfaction in the teaching and learning processes (following Mayer et al. 2017).

Teacher Self-Efficacy and Mobile Computing and Learning

Over the years, results of research studies have consistently indicated the importance of the significant relationship between teachers' feelings of technological self-efficacy which include feelings of technological self-confidence and the efficient use of technology in their classroom activity. Recent studies confirmed the existence of a reciprocal relationship between self-efficacy and technological self-confidence of teachers and their use of mobile learning applications. In addition, it has become increasingly clear that technological self-efficacy and self-confidence of teachers in the use of mobile computing and learning tools is a major affective variable significantly aligned with the enhancement of students' learning and achievement (following Varol 2013; Katz 2014).

In sum it may be concluded that self-efficacy that includes technological self-confidence is a key factor motivating teachers to use mobile learning strategies in their classrooms. When teachers perceive themselves to be in command of technology in general and mobile learning in particular, the way is then clear for them to employ mobile learning delivery platform tools for the benefit and enhancement of their students' all-round performance.

Conclusion

Over recent years it is becoming increasingly more apparent that the different mobile learning delivery tools and applications that have been developed for use in the educational process have positively contributed to the enhancement and upgrading of teaching and especially learning. As these mobile learning tools evolved and the learning platforms became more sophisticated, mobile learning has become more teacher-student interactive, student-centered, and student-friendly and has led to the enhancement of cognitive input that in turn promotes increased student achievement, effective learning outcomes, and positive affective attitudes toward the learning process. Mobile learning delivery utilizing the advantages of handheld devices, and especially

smartphones, is steadily becoming a legitimate and valued educational possibility and is rapidly changing the future of schools and learning paradigms.

Technology in general and particularly mobile computing have the potential to bring about a dramatic positive change in teaching and learning. Research over the years has indicated that mobile computing contributes to students' cognitive performance as well as to the enhancement of affective variables such as autonomy, creativity, flexibility, motivation, satisfaction, and self-efficacy (which includes technological self-confidence) that have a special relationship with the enhancement of teaching and student learning and performance. Thus, educational authorities are urged to provide the necessary educational and budgetary resources to develop the mass use of mobile computing in the educational system.

Introduction

The last two decades have witnessed an unprecedented growth of mobile technology. Mobile devices such as cell phones, smartphones,

notebooks, eReaders, portable music and video players (such as the iPod), handheld computers, game consoles, and other devices have permeated many facets of our lives (Kukulska-Hulme and Traxler 2008). However, cell phones are the most used of the above devices since they are multifunctional, and they can serve multiple functions including: making calls; surfing the internet; accessing resources; reading books; connecting with others through social media; taking and viewing pictures and videos; and creating, accessing, sharing, and distributing information (Godwin-Jones 2011). The multimedia functionality and its simpler and user-friendly interface make cell phones easier to be used by people who may not have access to or who may be uncomfortable with using other technologies such as desktop computers.

Cellphones in Education

Within the education setting, the penetration of cell phones has been noticeable. While debates on whether cell phones are a beneficial resource or a destructive distraction rages on, the opportunities presented by cell phones cannot be ignored. In reality, mobile technology continues to offer opportunities for different types of instruction and interaction in a flexible and accessible manner (Hyman et al. 2014). The potential for using cell phones in education is enormous in countries of limited resources where there is: no infrastructure to support Information Communication Technologies (ICT); lack of or limited electricity lines and telephone networks; and inaccessible network configurations. These infrastructural challenges facing many countries in the developing world have led to the rapid growth of wireless infrastructure. Cellphone users in Africa have increased at an annual rate of 65%, twice the global average, and more than 70% of those cell phones have internet access (Rao 2011). The number of people with cell phones in Africa grew from 7.5 million in 1999 to 76.8 million in 2004. As far back as 2005, mobile phones were said to be catapulting Africa into the twenty-first century (LaFraniere 2005). This claim was based on the statistics

available at the time, reflecting that 1 in 11 Africans owned a cellphone. In 2017, the number of mobile broadband connections had risen to close to 420 million, according to the report released by Ovum forecaster data service (Reed 2017). In South Africa alone, 75% of those living below the poverty line owned cell phones (Pyper 2013). In 2016, the ownership of cell phones had surpassed the population of South Africa by about 30 million connections and more than 60% of users were browsing the internet from their cell phones. South Africa ranks fifth in the world for mobile data usage, ahead of the USA, which ranks seventh. Therefore, cell phones are, for network access, most suitable in developing countries because they are affordable and have the ability to connect less privileged people to information.

Mobile Learning

The increased access and use of cell phones offer many possibilities for education because they make teaching and learning available anytime and everywhere (Zawacki-Richter et al. 2007). The integration of mobile technologies and learning is referred to as Mobile Learning (mLearning). A cursory definition of mLearning might limit mLearning to using a device that could be carried around for learning. This definition might be flimsy and overlook other important aspects of mLearning. For example, such a definition might suggest that reading a book while on a bus is part of mLearning (Harris 2001). Perhaps the first thing to acknowledge is that it is difficult to define mLearning, particularly because it has to take into cognizance the mobility of the learner, the technology, as well as learning itself (Brown et al. 2010). For many years, there have been attempts at a common definition of mLearning. As far back as 2007, Traxler used past research to categorize definitions of mLearning, which included the following: mLearning is technology-driven; it is a portable version of e-learning; it constitutes connected learning; it is personalized and situated; and it involves supporting student learning and development even when students are located in remote and rural places. These definitions showed

that there was a need for a definition that would depict the multifaceted nature of mLearning and such a clearer definition would, according to Brown and Mbat (2015), strengthen the concept of mLearning. One definition, which embodies the aspects of mLearning, has been provided by Crompton (2015) who has defined mLearning as “learning across multiple contexts, through social and content interactions, using personal electronic devices” (p. 4). This definition focuses on the learner, learning itself, as well as the device used.

MLearning has the potential to provide immense benefits for education in varied contexts. Ideal technologies for education are those that take into cognizance affordability, accessibility, connectivity, and usability (World Bank 2012). The portability of the device, multiple features in mobile devices, the accessibility of technology, as well as the pedagogical prospects all make mLearning appropriate to meet different teaching and learning needs. Thus, the affordances of cellphone use for learning open up new opportunities for exploring the benefits of these ubiquitous devices as delivery for interventions in teaching and learning (Kukulska-Hulme and Traxler 2005).

Context of mLearning

In the early days of investigating how mobile devices could be used for education, mLearning was defined and described mainly from a technocentric view. This initial view of mLearning did not take into consideration the sociocultural issues that may influence the lecturers’ and learners’ attitudes towards using cell phones as a delivery tool. Many years ago, Traxler (2007) argued that mLearning should be conceptualized from the perspective of learners’ experiences rather than the affordances of the technology tools. This balanced perspective is the one that merges the affordances of mobile devices and its characteristics with sociocultural features of the students’ contexts (Kearney et al. 2012). The starting point in using mobile devices for enhancing and supporting teaching and learning, therefore, is examining the context of learning, because it

plays a major role in any teaching and learning endeavor. According to Cole (2003), context is a set of circumstances that an individual interacts with and which are said to influence an individual in various ways. These individual contexts such as the family, society, political, and historical circumstances tend to influence how a child develops (Cole 2003). In the digital era, these contexts may be expanded to include technology, experiences, beliefs, and values that shape and confirm learning practices (Lave and Wenger 1991). Therefore, it is important that pedagogical principles should be guided by the context in which learning is to take place. This shows that human behavior is located within a social environment that influences an individual in various ways. It is therefore important that the analyses of mobile learning should include cultural-historical activity systems, mediated by tools that both constrain and support the learners and this is strongly mediated by its context rather than the educational content (Sharples et al. 2005).

The most significant attribute of mobile technologies, according to Kukulska-Hulme and Traxler (2005) is their ability to support situated learning. In this context, students are able to explore, share, and interact with each other as they try to learn together. Based on the criteria of interaction, independence, access, and flexibility, it can be concluded that mobile learning holds much promise provided that it is integrated into the mainstream provision of education and training especially in developing countries. In the South African context, most students cannot afford computers with internet subscriptions, and access to electricity is still a struggle for those who live in remote rural areas. Many of those who study through Open Distance Learning (ODL) are working adults who have competing responsibilities between work, family obligations and studying (Fozdar and Kumar 2007; Prinsloo and van Rooyen 2007). Because they do not have time set aside for studying, it is important that lecturers take care when they design study material for these students. This means that curriculum developers and teachers should ensure that accessibility and flexibility are part of any ODL learning

program and delivery mode. In this context, giving students these options is not an after-thought or a luxury, it is a necessity equaled to social justice.

MLearning has been utilized in a variety of contexts to serve a plethora of learning needs (Crescente and Lee 2011; Brown and Mbatia 2015). In an ODL environment where teaching and learning are characterized by physical as well as pedagogical separation between students and lecturers (Moore 1993), cell phones provide a range of possibilities for the delivery of distance education. The use of this ubiquitous device is even more critical in ODL contexts where students are faced with a myriad of challenges that are associated with the distance nature of learning. One major challenge in distance education is interaction. The feasibility of interaction in its varied forms, therefore, is onerous, owing to the physical as well as pedagogic distance between students and their lecturers and among the students themselves. The role that communication and interaction play in the learning process cannot be underestimated in teaching and learning paradigms. Mobile technologies thus provide opportunities for optimizing interaction and communication among distance students.

While the cellphone as a device provides ubiquitous and flexible access to content and interaction, such benefits are accentuated and supplemented with mobile applications (apps). Cellphone apps have transformed cell phones to devices for, among others: information creation, editing and sharing; spaces for educational and recreational content as well social forums for discussions. Social media such as Facebook, WhatsApp, Twitter, and Instagram have been used successfully to provide interactive spaces that have enhanced a sense of community among students. Research has demonstrated how WhatsApp can be used to facilitate learning (Bouhnik and Deshen 2014); how Twitter can be used to support online group journaling (Ferguson et al. 2017); teaching vocabulary through Facebook (Ventura and Martín-Monje 2016); as well as comparisons between a traditional educational platform Moodle and traditional social platform Facebook for

group discussions (DeSchryver et al. 2009). Through these mobile-based social media, distance students are granted opportunities for learner support.

At one of the largest distance education institutions, the University of South Africa (Unisa), cell phones have been used mainly for administrative purposes during applications, registrations, assignments, and examinations, particularly with announcements. For example, students are alerted to changes to assignment submission dates through short messaging systems (SMS). Unisa has also integrated mLearning in the library system where the mobile library resource, m-oasis, allows students to search for resources and request them. Of late, Unisa has embraced mobile assessment by introducing an app for submitting multiple choice question (MCQ) assignments through their cell phones. Over and above cutting down on submission times, the mobile MCQ submission is convenient for the students. With regard to actual teaching and learning, a recent study investigated the use of an existing social app – WhatsApp – and a newly developed app for teaching and learning vocabulary at Unisa (Shandu 2017).

Thus far, cell phones have been used for administrative and social support, while recently there is a move to provide cognitive support where students are encouraged to solve problems as they learn. All these interactions have been facilitated and augmented by mobile learning technologies because they are flexible, available, and cater for a myriad of interaction activities (Traxler 2009). The versatility of cell phones is highlighted by Sarraf et al. (2016) who have argued, “Learners can access the required information irrespective of time and location” (2016: 102). What is important is that students interact not only with each other or with their lecturers, but the cellphone itself provides interaction with the content through interaction with the device. It is, therefore, important to reiterate that interaction is not limited to human-human interaction because human-device interaction is also viable and beneficial to facilitate learning. Through the integration of technology in distance learning, quality education has been made accessible at very low cost to a large number

of people who are engaged in other activities of daily living that are likely to bar them from attending schooling on a regular basis (Bollag and Overland 2001).

Pedagogy of Mobile Learning

In trying to understand how mobile technology can be appropriated for teaching and learning at a distance, it is imperative to start by looking at how different mobile learning is from other technologies that are used in teaching and learning (Laurillard 2007). The strength of using mobile technologies is that they offer learning that is intimate, spontaneous, pervasive, and versatile. Mobile learning “provides an enhanced cognitive environment in which distance learners can interact with their instructors, their course materials, their physical and the virtual environment” (Koole 2009: 38). The delivery of content in distance education has to be accessible to students wherever they are and they can study anywhere they want. Therefore, the delivery mode for learning has to be flexible without being tethered to a particular spot or otherwise that would constrain access. It is in this regard that distance education researchers and practitioners continually explore various strategies for enhancing teaching and learning at a distance. One such strategy is to use mobile learning where practitioners take advantage of the ubiquity and wide ownership of mobile telephones for student support. The advanced technological enhancement as well as the range of possibilities for using cell phones for teaching and learning provides opportunity for authentic learning where students participate in the actual work related to their studies.

Kearney et al. (2012) identified three constructs that characterize the pedagogy of mLearning and these include collaboration, authenticity, and personalization. Collaboration enables students to make rich connections with each other. Mobile devices offer a high degree of networking among students. The devices give students an opportunity to learn together through sharing information, developing content, and

solving problems. The idea is to use social networks that students are familiar with to develop socially interactive learning environments as they consume, produce, and share a wide array of information and artifacts across time and place (Kearney et al. 2012). When students are in control of their learning, they are able to link up with other students in collaborative learning networks. Through peer collaboration, according to Laurillard (2007), students are more likely to be motivated to share their work with each other as well as to augment their conceptual understanding with others. In the distance education context, social interaction relates to the socio-emotional aspect of group forming and group dynamics (Kreijns et al. 2003). Mobile learning facilitates this process through building communities of learners who are committed to working together to achieve a goal. “Collaborative learning leads to deeper level learning, critical thinking, shared understanding and long term retention of the learned material” (Kreijns et al. 2003: 336) as well as developing communication and social skills.

While collaboration offers networking space for distance students, the authenticity construct highlights the opportunity for situated learning, while personalization has strong implications for ownership, agency, and autonomous learning (Kearney et al. 2012). When students have control over the physical or virtual learning spaces, the pace at which learning takes place and the time they learn, they tend to enjoy autonomy and are able to create a personalized, tailored learning journey (Kearney et al. 2012). Through multimedia capabilities, mLearning caters for innovative ways to teach such as using augmented reality (Johnson et al. 2009; Cook 2010) which refers to applications where digital objects are related to physical objects (Specht et al. 2011).

Uses and Benefits of mLearning

In addition to providing a space for collaborative learning, mLearning can be used to deliver

content, to facilitate assessment, and to deliver administrative information. Content delivery is another use for mobile learning, although Thornton and Houser (2001) caution that content in mLearning should be delivered in bite-size chunks for convenience. Reading long and bulky documents on a small screen can be tedious, at the very least. However, mLearning does not provide bits of content, but rather “small components, activities or events within any mode of delivery” (Brown and Mbat 2015: 118). Closely linked to content is the use of mLearning for assessment purposes. Mobile telephones, from a very basic model to the more sophisticated smartphones, have been successfully used for assessment such as for university entrance examinations (Laborda et al. 2011). The most basic cellphone can use short message services (SMS) and unstructured supplementary service data (USSD) where questions such as multiple choice questions (MCQs) are answered by sending the corresponding option as a response to questions. These methods do not require internet connections. The more sophisticated smartphones can use more interactive applications and quick response (QR) codes for quizzes to help students move forward through their materials. Mobile assignment submission apps are also used for submitting multiple choice question (MCQ) assignments.

mLearning can be used for administrative purposes by sending notices, announcements, and reminders and is also used for application and registration purposes. At Unisa, for example, when students apply for study at the university, they receive an SMS acknowledging the receipt of application, and they get regular updates regarding their application process. When a student's application has been approved, the student receives an SMS with a link that the student can click to “accept” the offer to study at Unisa. Libraries are also utilizing a mobile version of the catalogue system, which enables distance students to search the library catalogue; requesting materials and contacting subject librarians is convenient and fast. In the past, all these activities were done in person or by sending letters to

distance students via snail mail. These means were not only expensive but were also time-consuming.

The current developments in mobile telephone technologies have seen the rise of mobile apps being used for language learning (Godwin-Jones 2011). While in the beginning, mobile learning leant on SMSes such as that shown in the study by Thornton and Houser (2001), there is currently a myriad of interactive apps specifically for language learning. One such app-based study was conducted by Butgereit and Botha (2009) who used a mobile-based language learning application called Hadedu to encourage high school students to practice spelling or memorize vocabulary through mobile telephones. The vocabulary app was a collaborative effort between teachers and parents who selected the vocabulary to be learned and loaded vocabulary onto a web-based program which, in turn, converted the vocabulary from text to speech and was sent to the learners' mobile telephones as vocabulary exercises. On the web interface, users had a choice of language between English, Afrikaans, Swahili, French, and German and the selected language would correlate with the sound file created for the pronunciation of vocabulary. While there are many apps specifically for vocabulary learning (Siskin 2009), researchers and practitioners have started to explore how social media apps can be appropriated for learning.

New apps, such as WhatsApp, cater for messages in voice, images, video, and typing formats with no limit on the number of characters one can type. One can also send emojis as a nonverbal means of communicating their feelings; users are also able to create groups for interaction. In Barhoumi's (2015) study, it was found that an experimental group that received an extra hour of course discussions on WhatsApp outperformed the control group in the achievement test results. The experimental group displayed more positive attitudes towards learning and the course than the control group. Although it could be argued that the experimental group's performance and attitude gains were based on the extra attention they received (3 h compared to 2 h), the study, nonetheless, shows a

positive uptake of mobile learning where apps, including those that had been traditionally for social media purposes, are now being explored for learning purposes.

In another study, WhatsApp was used to facilitate communication among more mature students. The findings revealed that WhatsApp facilitated the creation of bonds and relationships among the participants (Gachago et al. 2015). The researchers concluded that "the accessibility and immediacy of WhatsApp as a mobile technology using learners' mobile phones, helps in facilitating the coordination of learning, blurring physical and geographical boundaries" (Gachago et al. 2015: 184). A study on the pedagogical suitability of using MXit – a cellphone instant messaging software application developed in Stellenbosch, South Africa – revealed that the social network provided users with a relaxed environment that they owned where they socialized and exchanged ideas in a language with which they felt comfortable (Makoe 2010).

Keegan (2005: 14) argued, "It is not technologies with inherent pedagogical qualities that are successful in distance education, but technologies that are generally available to citizens." Availability is the underlying and foregrounding principle driving mLearning to be considered as more beneficial over other modes of learning. According to Duman et al. (2014), the benefits of using cell phones for learning mainly include accessible content, available support, as well as facilitation of much-needed interaction.

Other benefits of mobile telephones are related to the convenience of the devices themselves in that cell phones are less expensive than computers and laptops (Chinnery 2006). These devices are cheaper to charge, so where electricity is scarce, students can keep their cell phones operating. The portability of mobile devices is another benefit that Traxler and Kukulska-Hulme (2005: 5) point out; mLearning devices are lightweight and handheld, while the sophistication of newer mobile devices is enticing. Because of the endless possibilities of multimedia one can access using mobile devices (Brown et al. 2011: 144–158), mLearning has been used for graphic audio-visual

ways to complement learning (Huang and Huang 2010). Voice recordings also allow learners to replay content as often as they wish. An advantage of this is that the learner carries this learning environment around with him or herself wherever he or she goes, learning anywhere, anytime and at their own pace.

Challenges of mLearning

Despite the documented benefits, mobile learning has not been embraced as much as it could in many developing countries. The reasons for the lack of uptake range from those that are human related – such as students’ and lecturers’ lack of familiarity and readiness – to those that are technology related – such as familiarity and maintenance of devices and apps. Many of the struggles to operate in the digital era are due to lack of the necessary skills to teach stakeholders how to use the devices. In addition to lack of skills, cell phones are primarily used for noneducational purposes such as keeping in touch with friends and family; having to use the same device for learning is a challenging shift for many. Lines become blurred, therefore, between learning through the cellphone and the distractions of social media (Gikas and Grant 2013).

A further challenge to mLearning relates to the financial implications of owning a cellphone. The reality is that students are sometimes not able to purchase their own mobile telephones or the data and airtime needed to keep them connected to the network. Sometimes students resort to using cell phones owned by family members and this makes learning difficult (Kajumbula 2006). In this case, the ubiquity and all the benefits of mLearning would be dependent on the cellphone’s availability. In developing countries, such as South Africa, sometimes the cellphone can be available, but its functionality limited by exorbitant service and data charges. While universities, such as Unisa, have taken strides in making wireless internet available at campuses, distance learning students still need to pay for data charges.

In the past, the challenges related to mobile devices used to refer mainly to the size of the

cellphone screen, which tended to be too small for effective interaction with bulky materials. In mitigating screen size concerns, mLearning emphasized that materials had to be delivered in short concise chunks (Thornton and Houser 2002: 236). Closely linked to screen size, there used to be issues of limited audio-visual quality related to the features of cellphone and data size including “one finger data entry which may be time-consuming” (Chinnery 2006: 13). While these concerns used to be valid challenges to mLearning, it should be noted that mobile devices are improving frequently in terms of functionality and user interface. A decade ago, Chinnery (2006) posited that mobile devices had limited nonverbal communication and limited message length. However, modern day cell phones have improved with bigger screens, clearer image resolution, as well as increased memory for more activities, and they also have apps such as WhatsApp that allow for longer texts and also cater for images, audio, and video content.

Perhaps the most immediate and pressing challenges regarding mLearning are the issues of security and privacy. Security pertains to the device as well as the information contained in the device. In a study conducted in Ghana (Tagoe and Abakah 2014), one of the challenges expressed by participants was the theft of devices, which meant the loss not only of the device but also of the materials therein. Apart from the device concerns, there is a more inconspicuous yet more destructive danger of unauthorized access (Little 2013) to information within cell phones through malware and other hacking mechanisms. MLearning programs are under pressure to achieve data confidentiality and integrity (Sarrab et al. 2016) to ensure that students’ information such as personal details and results are protected. Whether from device or information concerns, Kambourakis (2013) found that security misgivings “can hamper the penetration of mobile technologies into the education realm, and hence prevent stakeholders from capitalizing on the benefits that these technologies bring along” (2013: 68). While these security concerns are valid, it might be that education on safety and security can be a proactive line of defense prior to initiation of mobile-based interventions.

Conclusion

The cellphone has evolved from being a device for calls and messages into a palm-sized computer with multiple functions. With mobile apps, cell phones have been transformed into multimedia devices, which are part of everyday lives. While cell phones have been appropriated for learning through mLearning, the opportunities for interaction and student support have been more marked for distance education, particularly in developing countries. It is acknowledged that technological and human-related challenges still exist, yet the benefits of multifunctionality, accessibility, and availability related to mLearning are substantial.

Connected learning; e-learning; m-learning;
Seamless learning; Technology-enhanced learning

Introduction

Mobile learning or m-learning, derived from e-learning (Ozuorun and Tabak 2012), and being a subfield of technology-enhanced learning, has

become a prominent research field in the last decade. We have now amassed a wealth of case studies investigating different aspects of the design and implementation of mobile learning environments, as well as a number of reviews synthesizing mobile learning outcomes (e.g., Bano et al. 2018; Crompton et al. 2018; Fu and Hwang 2018; Ibáñez and Delgado-Kloos 2018). While unsurprisingly mixed findings have been reported in the literature (Zydney and Warner 2016), there is strong evidence to show that mobile learning has the potential to facilitate and enhance collaboration, learner agency, and creativity, which are essential competencies of the twenty-first century (Pargman et al. 2018). It has also been highlighted in the literature that mobile learning can be motivational and engaging. The recent US Speak-Up survey (2017) reported that three-quarter of its 36,860 responding teachers felt that the leading benefit of using mobile devices in the classroom was an increase of student engagement (other benefits include preparing students for college/work, increasing access to online content, personalized learning, and facilitating collaboration). This finding is encouraging, since we know that the lack of interest in schooling has become a major issue in the twenty-first century. For example, it has been reported in Iceland that 55% of its upper secondary students do not complete their 4-year program due to the lack of motivation (Kjartansdóttir and Jakobsdóttir 2016).

The prevalence of smartphones and tablets and recent advent of augmented reality, virtual reality systems, and wearable technologies have the potential to generate new learning opportunities, both in- and out-of-school. However, while technology enthusiasts advocate the increasing use of advanced mobile technologies to support and enhance learning across contexts, researchers, practitioners, and policy makers are reminded that there are many challenges in researching and implementing mobile learning environments in formal and informal settings (Lewin et al. 2018). The purpose of this chapter is to interrogate the literature of this emerging field to identify and highlight these challenges and suggest possible pathways for researchers, practitioners, and policy

makers to move forward. In the following section, we will first discuss the changing conceptions of mobile learning to provide a context to better understand these challenges. Then we will discuss some the pedagogical, research, and policy challenges that we currently face.

Mobile Learning Contexts

While there is little disagreement on the unique characteristics of mobile devices, such as “individuality, connectivity, context sensitivity, mobility and immediacy” (Song et al. 2012, p. 680), there is yet no consensus as to how mobile learning should be conceptualized. We note that there has been an evolution of understanding of mobile learning in the last two decades. Earlier definitions of mobile learning were primarily techno-centric in nature (Pachler et al. 2010), focusing on the design and use of mobile technologies to enhance formal learning, and mobile learning was often considered a subset of e-learning (Winters 2006). In the last decade, however, mobile learning research has shifted to focusing on the mobility of the learner and context (Kukulska-Hulme et al. 2011). Increasingly there is a recognition that mobile learning design is not primarily about the technology, and using mobile technologies in the classroom, e.g., providing iPads to students with pre-loaded course content, does not necessarily foster mobile learning (Philip 2017). There has also been a shift away from viewing mobile learning as using technologies to enhance access to information or content. As pointed out by Pachler et al. (2010), mobile learning “is not about delivering content to mobile devices but, instead, about the processes of coming to know and being able to operate successfully in, and across, new and ever changing contexts and learning spaces,” and therefore, it is “not primarily about technology” (p. 6).

Current research on mobile learning highlights the importance of context, emphasizing the varying learning experiences that students can acquire and develop in and across contexts (Sharples 2015a). For example, Crompton (2013) considers mobile learning as “learning across multiple

contexts, through social and content interactions, using personal electronic devices” (p. 4), and Sharples et al. (2007) characterize mobile learning as “the private and public processes of coming to know through exploration and conversation across multiple contexts, amongst people and interactive technologies” (p. 255). Increasingly it has been recognized that learning can take place in physical and virtual sites, as well as in- and out-of-school spaces and contexts, and the emphasis is on “boundary- and context-crossing” (Pachler et al. 2010). Other than the spatial context, the temporal context of mobile learning is also considered important by many scholars. As Norris and Soloway (2018) contend, “mobile *learning* is about support for 24/7, *all the time, everywhere* learning” (p. 860, italics in the original). There are other contextual aspects that are also considered pertinent in mobile learning. For example, Kukulska-Hulme et al. (2011) have highlighted five contextual aspects of mobile learning that we need to consider when designing mobile learning environments, that is, the physical context (physical space), conceptual context (conceptual space), social context (social space), technological context (technologies used), and temporal context (learning over time). Sharples (2015a) argues that it is important to understand the interrelationship between “learning through context,” “learning in context,” and “learning about context” when designing mobile learning environments.

Investigations have been conducted to explore the impact of the physical space or physical environment on mobile learning, and Bligh and Crook (2017) remind us that different spaces have different effects on learning and the learning space of mobile learning should be different from structured formal learning. Recently attention has been focused on how flexible learning spaces are designed so that different forms of learning (individual/collaborative, formal/informal) can be accommodated and connected within the same physical and social environment. These so-called innovative learning environments (ILE) are well supported by networking technologies with high-speed connectivity to facilitate social and informal learning (Bligh and Crook 2017). They are learning spaces created in a formal setting where the

learner is located but virtual presence is simultaneously afforded and mobility across virtual spaces effectively facilitated (Leander et al. 2010).

Erstad (2012) points out that for young people, learning can be a “constant flow of activities” (p. 26), which happens within and across contexts involving online and offline activities. As such, mobile learning research needs to shift its focus from studying a static learning environment to learning trajectories (Leander et al. 2010) in order to recognize learning undertaken in both in- and out-of-school settings. It is noted by Cross (2006) that formal learning has long been overvalued and privileged over other forms of learning, even though people only spend about 10–15 per cent of their total lifetime learning in formal settings. With increasing attention to the importance of lifelong learning in the twenty-first century, how we can bridge formal and informal learning has become a key educational issue (Lewin et al. 2018).

Why is it important to connect learning across contexts? After conducting a review of the literature, Rajala et al. (2016) come up with three pedagogical rationales to justify why formal and informal learning should be connected. The first rationale is to promote educational equity and inclusiveness. They point out that out-of-school knowledge held by underprivileged students is often undervalued and there is a mismatch between knowledge acquired from in-school and out-of-school settings. There is thus a need to address this inequity issue and to legitimize out-of-school knowledge. The second rationale for connecting formal and informal learning is the need to respond to the requirements of the twenty-first century. Rajala et al.’s (2016) review shows that “everyday reasoning and cultural practices” (p. 22) can contribute to a better understanding of school subjects such as science, music, language, math, and sports. A seamless connection can help students develop creativity, active citizenship, and self-directed learning skills. The third rationale acknowledges the importance of the learner’s learning ecology (Barron 2006) which includes a diversity of learning contexts and spaces in supporting development of learner agency and identity.

The term seamless learning is gaining popularity. Recognizing the important link between contexts, Chan et al. (2006) use the term seamless learning to describe continuous learning across different environments supported by mobile devices. In seamless learning students:

can learn whenever they are curious in a variety of scenarios and that they can switch from one scenario to another easily and quickly using the personal device as a mediator...exploration and investigation in the seamless learning space provides a potential to extend formal learning time...into informal learning time, to embrace opportunities for out-of-school learning. (p. 6)

According to Milrad et al. (2013), seamless learning is characterized by seamless adaptivity and connectivity. Seamless adaptivity refers to the use of mobile technologies to provide context-aware contents or services to the learner. Educational augmented reality applications are examples of how context-aware content can be seamlessly provided to the learner. Seamless connectivity means using mobile technologies to enable the learners to continue their learning across devices and settings disregard where they are located.

Researchers also use the learning lives approach (Erstad et al. 2016) or connected learning model (Ito et al. 2013); Kumpulainen and Sefton-Green (2014) to conceptualize boundary crossing between different learning sites and practices. Ito et al. (2013) explain the concept of connected learning:

Connected learning is realized when a young person is able to pursue a personal interest or passion with the support of friends and caring adults, and is in turn able to link this learning and interest to academic achievement, career success or civic engagement. This model is based on evidence that the most resilient, adaptive and effective learning involves individual interest as well as social support to overcome adversity and provide recognition. (p. 4)

Based on the learning lives or connected learning approach, learning activities are designed to cut across boundaries which allow students to make connections of what they learn in different contexts. This design approach is similar to what Mikkola and Kumpulainen (2016) called hybrid learning, aiming to engage students in learning

activities designed to bridge academic and everyday knowledge. In hybrid learning, students are encouraged to use the “material, sociocultural, linguistic, and cognitive resources embedded in their lifeworlds” (p. 173) to enrich academic activities. They gave an example of a yearlong musical production where 11–12-year-old students were asked to write musical scripts in groups. Students were given a personal netbook with collaborative writing and online chat tools to work both in and after school. With the support of mobile devices, the students worked collaboratively across time and space, and they considered their work undertaken in multiple sociocultural contexts as equally valued. Mikkola and Kumpulainen’s (2016) study highlights the importance of transforming the pedagogical culture of the school to support students to engage in holistic learning in both in- and out-of-school contexts.

With the recent advent of augmented reality (AR) applications, mobile learning has taken a step forward in situating learning in the real world and in real time. Being recognized as one of the most promising learning technologies in recent years, augmented reality (AR) systems utilize 3-D technologies and location-aware applications to provide the learners with additional contextual information which is displayed on a head-mounted or handheld device when they interact with real-world objects (Ibáñez and Delgado-Kloos 2018). Learning in real-world contexts with AR systems may therefore increase content understanding (Hwang et al. 2013). As a form of inquiry-based learning, this mixing of the physical and virtual worlds may support the learner to conduct deeper and more creative investigations. AR systems have provided a new way for the learner to access information and content. Instead of using the mouse or keyboard, AR applications now allow the learners to use their bodies to interact with content, thus providing a different educational perspective and experience to understand content (Radu 2014).

Radu’s (2014) review shows that AR applications have the potential to improve understanding

of spatial structure and functioning, physical task performance, and collaboration. These applications may also enhance language associations, improve longer-term memory retention, and increase content understanding and motivation. Findings from the AR Heritage Trails project in Singapore or the AR Trails of Integrity and Ethics in Hong Kong show that the use of AR can help break down the classroom walls to situate learning in the real world (Pegrum 2016). After reviewing 28 AR projects on STEM (science, technology, engineering, and mathematics) subjects, Ibáñez and Delgado-Kloos (2018) categorize three kinds of AR applications, namely, exploration, simulation, and game-based applications. Their review shows that a range of instructional strategies have been used in these applications, including both behaviorist strategies used to support content delivery and constructivist strategies such as simulations, and a few projects used collaborative learning strategies. Ibáñez and Delgado-Kloos (2018) conclude from their review that while these studies had provided some ideas of the affordances and barriers of AR applications, few of them discussed how learning actually took place within the AR environment. In a similar vein, Akçayır et al. (2016) point out that there are some pedagogical and usability barriers in AR applications such as teachers lacking understanding and experience of how to integrate AR into the school curriculum, and the AR systems (sometimes with rather bulky hardware) may be difficult to manage in a busy classroom. In addition to augmented reality applications, recent advent of wearable digital devices such as Google Glass that “incorporate wireless connectivity for the purposes of seamlessly accessing, interacting with and exchanging contextually relevant information” (Bower and Sturman 2015, p. 344) may create new learning opportunities. However, as pointed out by Bower and Sturman (2015), while pedagogical uses of wearable technologies have been suggested in the literature, so far limited empirical research has been conducted to show how they can actually be used to support teaching and learning in the classroom.

What Are the Challenges?

While there is high hope that mobile technology may transform education, there is some concern that this is just another wave of technology that might end up with limited use and impact, as what Cuban (1986) has insightfully predicted over 30 years ago on technology use in education. There is a concern that mobile learning may become just another fad of technology-enhanced learning (TEL), focusing only on the technology itself but not pedagogical integration (Maddux and Cummings 2004). We note that mobile technologies have unique affordances well suited to support mobile learning; however, we need to first address some challenges that we currently face.

Pedagogical Challenges

The EDUsummIT (International Summit on ICT in Education) thematic working group on mobile and informal learning (Khaddage et al. 2015; Lai et al. 2013; Lewin et al. 2018) has identified a number of pedagogical challenges of mobile learning, and the following discussion will focus on three of them. The first challenge is the need for teachers to reconceptualize learning as mobile (Traxler 2010). The second challenge is the need to develop new pedagogical designs and practices to integrate academic and everyday knowledge across contexts, recognizing that contexts can shape digital practices and digital practices developed in one context may not be readily transferable to another context (Sharples 2015a). The last challenge is the need for students to develop self-directed learning skills to self-manage, learn how to engage in critical reflection, and be resilient in different mobile learning contexts (Khaddage et al. 2015).

The need for a deeper understanding of mobile learning. Currently many teachers only have a superficial understanding of mobile learning and are unaware of its transformative power on learning experiences. This is not surprising, since although digital mobile devices have been widely used by children and youth, they are not yet widely used in schools to support teaching and

learning (Kjartansdóttir and Jakobsdóttir 2016). Even when they are used in schools, teachers often use them to substitute or augment existing practices (refer Puentedura's (2006) first two steps of the SAMR model). They simply follow what they routinely do when using digital technologies in teaching. As pointed out by Traxler (2010), while teachers may see technology as mobile, they do not see learning as mobile. When describing the US mobile learning landscape, Evans (2018) has a similar observation:

The adoption process for the use of mobile devices in the American classroom has followed a traditional technology adoption pattern... Too little emphasis is on the more important aspects of mobile learning usage... that enable and empower new learning modalities and approaches that transcend traditional learning practices. (p. 787)

This is largely due to the fact that teachers do not have a good understanding of the pedagogical affordances of technologies in general and, in particular, the unique affordances of mobile technologies which can facilitate out-of-school learning and add value to academic learning and thus make formal learning more relevant to students (Lai and Smith 2018). As discussed previously, mobile learning should be conceptualized as learning across contexts where different forms of knowledge are located, and this requires a change of the teacher's belief and identity. Erstad (2012) points out teachers need to recognize and value students' prior everyday knowledge and skills which they can draw on to augment academic work. One exemplar approach linking in- and out-of-school knowledge Erstad (2012) suggests is the Funds of Knowledge approach where teachers visit students' homes and communities to understand the knowledge that they have acquired in those contexts, and then use the information to make a connection to the formal curriculum, so as to make learning more meaningful to their students. This boundary crossing empowers students with agency to continue their learning trajectories from home and community to school.

Bjørgen and Erstad (2015) have studied primary students' in- and out-of-school digital

practices, and they found that contexts regulated and structured these practices, and students used digital media in different ways between the two contexts. In their study, Bjørgen and Erstad (2015) reported that out-of-school digital practices were considered by young people as more relevant and interesting, and they “framed school’s digital practices as irrelevant or meaningless for their leisure-time interests in technology” (p. 123). Their study shows that there are strikingly different school and out-of-school digital cultures and practices, and students may experience cultural clashes since there are different expectations from these learning contexts. Rajala et al. (2016) give an example that when using social media after school for formal school work, students expect that because it is formal learning and therefore they would use formal school language in their work, even though it is not the natural language they would normally use with these media. They suggest that young people’s digital practices are context dependent and they are difficult to transfer across contexts. The tension of mixing students’ informal Web 2.0 learning with formal learning has also been observed by Crook (2012), and he suggests that there are four themes of incompatibility between the two forms of learning, namely, inquiry, collaboration, publication, and literacy. It is clear that students’ informal learning experiences often do not fit in with the school learning culture. However, there can also be a semiotic relationship between digital practices in formal and informal contexts, with what students have learned and practiced in school influencing how they learn and practice in out-of-school contexts (Lai et al. 2013).

Implementing mobile learning in school also challenges the role of the teacher as transmitter of knowledge. Allowing students to access and use mobile devices in schools means teachers can no longer monopolize knowledge, and this has implications on the power relationship between the teacher and her students which may threaten the teacher’s identity (Biesta and Tedder 2007). Informal mobile learning also requires stronger learner agency to direct learning as compared to classroom learning where it is largely teacher-directed, with learning materials being prescribed and

learning sequence structured by the teacher. However, this does not mean that the teacher has little role to play in the mobile learning process, since totally unguided learning has been found ineffective (Kirschner et al. 2006; Mayer 2004). This is a question of how to balance the amount of guidance provided by the teacher and the degree of freedom that the student should have in controlling her learning. Unfortunately, the issue of learner agency in mobile learning has not been adequately addressed in the literature (Suárez et al. 2018), and there are epistemological and ontological issues of knowledge creation and transmission that needed further exploration, as suggested by Pachler et al. (2010).

Developing new pedagogies across contexts. In a report on mobile learning, UNESCO (2012) maintains that current pedagogical approaches are not appropriate to support the way the new generation of learners learn and as such an instructional paradigm shift is needed. The tendency for teachers to use new technologies including mobile devices to support existing practices, as pointed out by Erstad and Sefton-Green (2013), may be due to the need to promote standardization rather than develop students’ creativity. How to keep the learner motivated in learning is a challenge, since young people often feel that formal learning is disengaging (Philip 2017). While there is evidence to show that using mobile devices may increase motivation and engagement as compared to using other media in formal learning contexts (Jeno et al. 2018), how to sustain interest and engagement is an issue. We are reminded by Philip and Garcia (2013) that while technologies come with a novelty effect which can generate situated interest, innovative pedagogical designs are needed to sustain students’ interest to engage in deep learning.

Since mobile learning is learning on the move (Jaldemark 2018), a pedagogical challenge is to design different learning activities to “take advantages of different [learning] contexts” (Sharples 2015a). Ito et al. (2013) have provided several examples in their report of how learning can be successfully connected and supported by using a range of digital and mobile technologies. Hyvärinen et al. (2016) have provided an

interesting example of how an extended learning environment involving boundary crossing could be created by teachers in two Finnish primary schools. In their study the teachers firstly identified and recognize students' prior knowledge from informal learning and then planned authentic learning activities by extending academic work outside the school environment in collaboration with local partners. They coordinated with local partners such as flea markets, art projects, and the communal recycling center to create opportunities for learning activities. The teachers involved observed that these out-of-school activities could nurture curriculum and cross-curriculum learning. They also reflected on their practices and learning outcomes and found that the students had developed a range of skills through boundary-crossing activities, as well as gaining an understanding of learning for life and learning in community. Interestingly, this boundary crossing was also transformative for the teachers. Working in out-of-school environments has made them aware of new learning possibilities and shifted their role as a learner. The hybrid learning model proposed by Mikkola and Kumpulainen (2016) suggests that an effective way of boundary crossing is to create collaborative hybrid learning activities so that learners can use their resources from their lifeworlds in formal settings. However, we need to be cautious that in boundary-crossing, there are dangers in "bringing students' everyday life into schools" (Pachler et al. 2010), and the "pedagogisation of everyday life" (Sefton-Green and Erstad 2017), since students tend to resist the blurring of the boundary between academic and personal spaces (Lewin et al. 2018).

Mobile technologies such as smartphones now make one-to-one computing truly possible. However, if teachers use mobile devices to support content delivery in order to personalize learning, they need to realize that on the small cell phone screen, limited packets of information can only be presented at a time, and this chunked nature of information may lead to fragmentation of knowledge and undermine deep learning (Traxler 2010). When designing out-of-school tasks for informal learning using mobile technologies, teachers also need to pay attention to some psychological

challenges with learning on the move (Jaldemark 2018). Terras and Ramsay (2012) have identified five challenges, namely, the context-dependent nature of memory; human cognitive resources are finite; cognition is distributed and learning is situated; metacognition is essential; and individual differences matter. To tackle these challenges requires a design of informal learning tasks that allow the learner to successfully manage their learning in a distractive environment.

Mobile learning is often associated with inquiry-based learning conducted outside school. We are reminded by Sharples (2015b) that linking academic work undertaken in the classroom with work that students do in an out-of-school setting such as a museum can be demanding and unpredictable, and the teacher needs to consider how to maintain a continuity of learning across both contexts. There is a need for orchestration:

Orchestration of learning as the central issue in supporting a pedagogy of inquiry-based learning that encompassed teacher-initiated inquiry in the classroom, learner-managed investigation at home or outdoors supported by mobile devices, and group activity back in the classroom to synthesise and share findings. (Sharples 2015b, p. 50)

Orchestration also means an awareness of the distraction that the use of mobile devices would bring to the classroom. However, discouraging students from using mobile devices altogether during class time is an ineffective strategy even though distraction from multitasking is a real concern (Fuchs and Woessmann 2004). Whether multitasking is merited has been debated in the literature. In some countries, for example, Germany, multitasking skills are included in the school curriculum (Spitzer 2014). However, it is well recognized in cognitive psychology that multitasking is not an effective learning strategy when students are asked to perform complex cognitive tasks when focused attention is required (Lee et al. 2012).

Developing students as mobile learners. School learning is highly structured, with content being prescribed by the curriculum, and the time schedule for learning inflexible. For everyday learning, it is completely the opposite. Learners have no curriculum to follow; there is no structure

nor tutor to guide them (Lai 2018). To take advantage of the out-of-school learning opportunities facilitated by mobile devices, students firstly need to understand the value of informal learning, that learning is lifelong, life-deep, and life-wide (Cross 2006), and secondly develop the self-directed and collaborative learning skills required to manage informal learning successfully. As reported by Boticki et al. (2015) in their study of mobile learning with primary students, without teacher guidance students only had limited engagement in using mobile technologies for self-directed learning activities. In designing learning activities across contexts, teachers therefore need to design knowledge building activities to support learner agency where students would develop their own questions and solve problems as a community (Khaddage et al. 2015). Mobile learning also requires a change of assessment practices to avoid standardization of the learning tasks and outcomes (Hwang and Chang 2011). Although undertaken in higher education context, Lai and Smith's (2018) study has suggested four ways that teachers can induce their students to engage in informal learning. Teachers can make their classes more interesting which may trigger students' self-directed and follow-up learning in informal contexts. They may encourage students to be more independent and take responsibility for their learning. Teachers may also emphasize on informal and lifelong learning in class, provide learning resources to foster it, and support students to develop new learning skills such as collaborative knowledge building. Lastly, they may model informal learning in their class.

Research Challenges

Conducting TEL research has always been challenging, and studying mobile learning adds to the challenge. In the last 30 years, while TEL research has flooded the field, sadly, as pointed out by Selwyn (2012), the field of educational technology "has grown into a notoriously sloppy area of scholarship – brimming over with lazily executed 'investigations' and standalone case studies, while also tolerating some highly questionable thinking" (p. 213). In addition, there is a problem with reporting. Rather than reporting what has

actually happened in the classroom, many technology advocates published speculative works of what they thought should have happened and thus created the impression that the use of digital technologies in learning and education was vibrant and successful (Selwyn 2010). As a result, despite the excitement on TEL in general, and in mobile learning in particular, so far there is a lack of adequate evidence to support what Kozma (2008) called the "strategic educational ICT policy rationales" (p. 1085), and there is little evidence to show that so far ICT has advanced educational reform.

We find that implementation failures often follow from large-scale investments on digital technology. For example, the recent large-scale uptake of the iPads in California schools ended up in chaos (Philip 2017). The lack of credible evidence of success in technology use in education is alarming. When commenting on the effectiveness of mobile learning, Sharples (2013) maintain that "over the past ten years mobile learning has grown from small-scale studies to large national and international projects, but it still lacks an evidence base of comparative studies and research into large-scale deployment" (p. 5). Sharples' comment on mobile learning research is not surprising because even after over 30 years of research on TEL, with numerous studies being conducted in every school subject, Lawless (2016) points out recently that "taken as a whole, research on the effectiveness of general contemporary technologies does not yield enough decisive evidence to support conclusive proof of their effectiveness in improving educational outcomes" (p. 5). Similarly, according to an OECD (2015) study, there is a lack of evidence to show "appreciable improvements in student achievement in reading, mathematics or science in the countries that had invested heavily in ICT for education" (p. 15).

Scholars have identified problems in measuring technological effects in media comparative studies (e.g., comparing content delivered by a mobile app and a book). It is argued by Selwyn (2011) that since technology is embedded in a complex sociopolitical and economic system, one cannot take TEL out of its contexts and measure learning outcomes in isolation. Trying to

measure learning outcomes with any “degree of confidence or certainty over a discernible ‘cause-and-effect’ relationship between technology and learning is nigh on impossible” (p. 84). This points to the importance of studying the learning environment, not just the technology, or even the pedagogy. As pointed out by Clark et al. (2016), while technological applications/software provide new affordances, it is how they are used, and how the learning environment is designed which “leverage those affordances” (p. 116) that would affect learning outcomes.

While there are already huge methodological challenges in studying TEL, it is even more challenging when mobile learning is to be investigated across time and space, and there is a learning trajectory that has to be tracked. Thus, as commented by Leander et al. (2010), “a key challenge in researching mobilities involves a critical reassessment of the space–time shape and assumptions of research methods, assumptions, and modes of analysis” (p. 343). They maintain that there are difficulties in researching mobile learning because we are not studying a single event or site, but multiple events in multiple sites that have to be researched simultaneously, and there is a need to investigate the interaction and relationship between time and space. It is not just a question of what, when, and how data are to be collected; the complexity of the data also makes meaning-making difficult. For example, in conducting a seamless science inquiry project using mobile devices, Song and Ma (2013) commented that it was a demanding task to track the learning process, due to “the limited screen size, and the mobile nature of the activities, learning can occur in constantly changing contexts such as home, school and other spaces,” and there is a need “to examine holistically and “re-construct” learning occurring in different contexts” (n.p.). The lack of theoretical frameworks in mobile learning research adds to the difficulties (Baran 2014), since the majority of the mobile learning case studies were either not grounded in learning theories (Bano et al. 2018) or were based on behaviorist learning designs, involving, for example, drill and practice activities (Crompton et al. 2018). Also, these case studies were mostly

comparative studies investigating the effects of mobile technologies, and data were collected primarily from formal settings (Crompton et al. 2018). Some promising pathways to tackle these challenges may include using the learning lives approach to follow the learner’s learning trajectories across everyday life (Sefton-Green and Erstad 2017). Design-based research is also promising since it is a more holistic and participatory approach (Amiel and Reeves 2008). Ethnographic studies of different contexts may also be undertaken (Lewin et al. 2018), but as warned by Leander et al. (2010), “the ability of our empirical work to keep up with rapid changes in technology and, in particular, to account for the effects of these changes in the everyday lives of children and youth through ethnographic studies is called into question” (p. 374).

There are ethical issues specifically related to mobile learning research which are challenging. Wishart (2018) reminds us that the fluidity and unpredictability of mobile learning contexts and activities may create some unique ethical challenges. For example, Traxler and Bridges (2005) have suggested several ethical difficulties that may arise in mobile learning research, including the need to gain ongoing informed consent; anonymity of identity and confidentiality of data may not be fully kept in an online context; the participants may inadvertently access inappropriate materials online; and in cross-cultural studies, the economic and cultural diversity of the participants may create different expectations.

Policy Challenges

There are many structural constraints in using mobile devices to support learning across contexts. Schuck et al. (2017) remind us the inflexibility of the physical learning environment of the school and the rigidity of the temporal schedule of the curriculum as barriers. Lewin et al. (2018) point out the need to reform the standardized and highly prescriptive curriculum and high-stakes assessment which undervalue informal learning and discourage knowledge gained from out-of-school contexts using mobile devices being transferred and recognized in the formal school environment. In their study, Lewin et al. (2018) further

argue that since mobile learning is often spontaneous, flexible, and incidental, it often does not align well with traditional learning goals and objectives. Thus the challenge is how to develop pathways to recognize and accredit self-directed mobile learning undertaken in informal contexts.

This highlights the importance of professional learning and development. It has been well documented that effective teacher preparation and in-service professional learning and development are essential to drive change and innovative practices (Fullan 2015). Mobile learning requires a reconceptualization of learning and change of beliefs, which requires ongoing support and professional learning and development. However, so far little attention has been paid on supporting teachers of how to implement mobile learning in their class (Baran 2014). For example, as pointed out by Kukulska-Hulme et al. (2011), even in Europe where mobile learning has been heavily promoted in the last decade, there is little attention on developing teachers' pedagogical understanding of mobile learning. Technological training has also been neglected. While teachers do not lack experience and skills of using their own mobile devices such as smartphones, they lack technological skills in using new mobile devices for educational purposes (Pachler et al. 2010). How to motivate teachers to change and adopt mobile learning in their practice remains a significant challenge which has not been taken up seriously.

Many schools have adopted the Bring Your Own Device (BYOD) policy in order to promote mobile learning. This policy means students often are required to purchase their own personal devices, thus shifting the hardware and software costs to the parents. This has created an equity issue if parents cannot afford the costs. Also, this policy may create some new management or technical challenges. While BYOD may help reduce some of the technological and student training costs for the school, there are increased infrastructural costs for Internet connectivity and teacher training, as well as management and technical support challenges as a variety of devices may be used by the students (Khaddage et al. 2015).

Cyberbullying both in- and out-of-school has now been routinely reported in the media, with a rising trend in some countries (Eden et al. 2013). As defined by Kizza (2016), cyberbullying is the use of the Internet and mobile technologies with the intention of harming another person, and there are different types of cyberbullying, such as harassment, flaming, exclusion, outing, and masquerading. According to a recent Pew Research Centre national survey (2018), 59% of the American teenage respondents had experienced some form of cyberbullying, and the most common type of cyberbullying was offensive name-calling (42%). Other forms of cyberbullying included spreading false rumors (almost a third), had someone other than a parent tracking where they were (over one-quarter), and being the target of physical threats (16%). It is alarming that in this survey, 63% of the respondents considered cyberbullying a major problem, and 58% felt that their teachers had failed to address this issue. The need for a school-wide policy to inform teachers of how to tackle cyberbullying is clearly shown from the findings of this survey. In fact, in a study surveying the perceptions of cyberbullying of 328 school teachers in Israel, Eden et al. (2013) found that just over one-third of them were confident of dealing with cyberbullying cases, probably due to the lack of understanding of the issue (only 20% of the teachers were confident of identifying cyberbullying), and a majority of the teachers (65%) would like to learn more about cyberbullying. However, it is not clear whether the prevalence of mobile devices has led to the increase of the risk of cyberbullying. After reviewing the literature on the risks of online aggressive behaviors, Livingstone and Smith (2014) concluded that "the risks of cyberbullying, contact with strangers, sexual messaging ('sexting') and pornography generally affect fewer than one in five adolescents [and] despite the rise in children and young people's use mobile and online technologies, there is little compelling evidence that online risks are increasing commensurately" (p. 645). Nonetheless, they recommended that practitioners should be trained to understand and recognize the online risks

associated with the use of mobile technology and develop interventions and policies to mitigate these risks.

Conclusion

This chapter began with a discussion of the changing understanding of mobile learning in recent years, highlighting the recognition that context rather than technology should be the distinctive focus of mobile learning, but we also note that the techno-centric mentality of “what is being done is... simply because it can be done” (Norman 2013, pars. 16) is still pervasive. While there is no doubt that the unique affordances of mobile technologies are important in supporting certain learning strategies such as situated and constructivist learning, in conducting mobile learning research, we should be cautious not to focus just on the technological and pedagogical factors. We should also consider the broader sociopolitical and economic contexts where educational activities are embedded (Ito et al. 2013; Selwyn 2012). We also must admit that even after mobile learning has been around for over 20 years (we follow Norris and Soloway’s (2018) use of 1997 as the starting of mobile learning when the Palm III PDA first appeared in the educational scene), we still do not know much about how it can be effectively designed, implemented, and evaluated in and across learning contexts, and there are a number of pedagogical, research, and policy challenges that we need to tackle if mobile learning is to be successfully implemented. To tackle these challenges, we are reminded by Selwyn (2012) that we must be more critical, and there is a need to examine “how digital technologies (re)produce social relations and in whose interests they serve” (p. 219).

Introduction

Developing, managing, evaluating, and comparing strategies for problem-solving are central skills when handling demanding and complex problems, both in computer science and many sectors of the economy. Such strategies often exist in the mind of single individuals and are often based on intuition, experience, and personal knowledge. Especially when working in teams, it is a big challenge to find common means to clearly formulate, communicate, and evaluate strategies. Games and simulations are widely used nowadays to train specific skills in teams. Notable examples span a growing variety of professional areas. In emergency medicine and disaster management, for instance, the online European Master in

Disaster Management (<https://www.dismaster.com>) features the use of simulations and interactive media as an essential technology to bring together its global cohort of participants and have them cooperate in groups to solve complex collaborative scenarios. Crew training for aerospace missions, pilot training, and assessment have included for a long time simulations and games, and many new approaches to smart and connected health, smart manufacturing, and collaborative design use games or game-like simulations to train situated behaviors of increasingly complex nature. Such approaches have been called *serious games*, or applied games, for games designed for a primary purpose other than pure entertainment. This term is now widespread, although the traditional gaming industry dislikes it.

It has been confirmed by various studies that games and simulations have a positive impact on achieving learning goals (Vlachopoulos and Makri 2017). As remarked in (Juan et al. 2017), “the evolution of computer technologies, together with the increasing speed of Internet-based communications, has promoted the use of simulation software and serious games in higher education. These technological and methodological tools can significantly enrich the learning experience in almost any knowledge area. In particular, they will have a significant impact on how the learning process is performed in the so called Science, Technology, Engineering, and Mathematics (STEM) education.” Furthermore, games typically make attractive and engaging course topics for students of all ages (Juan et al. 2017); on balance, results indicate that games and/or simulations have a positive impact on learning goals (Vlachopoulos and Makri 2017) and game development allows students to experience various aspects of software development by systematically exploring the mechanics of a game. Modeling games and game strategies with **dedicated modeling environments** instead of implementing them with conventional programming languages or by just using pre-existing game engines focuses the attention on problem-solving. Students concentrate on understanding and managing the domain-specific essentials of the strategy without having to deal with the

technicalities of a programming language and coding. Not much literature is available yet on model-driven or model-based game strategy design and game development, so it is still difficult to quantify and give a systematic picture of their use in educational practice.

This entry presents and discusses three selected examples of short courses described in recent literature that use modeling of games and game strategies as a teaching tool (section “[Modeling of Games and Game Strategies as a Teaching Tool: Examples](#)”). It then discusses aspects relevant to the educational context in which they are used (section “[Discussion/Evaluation](#)”). Section “[Conclusions and Outlook](#)” concludes the entry with a summary and perspectives for the future.

Modeling of Games and Game Strategies as a Teaching Tool: Examples

This section reports on three examples of game and game strategy development that have been successfully used as modeling tools to teach computational thinking concepts, for which detailed accounts can be found in recent literature. The three examples are the ConnectIT game, used as a computational thinking approach to strategy design (Bakera et al. 2009); the ChainReaction game, used successfully in summer camps for girls (IEEE 2016; McInerney et al. 2017); and a virtual world application to serious games in business and entrepreneurship based on Second Life ([Science in 3D – BMBF-Projekt; Lehre in Virtuellen Welten](#)).

They all use the XMDD paradigm (eXtreme Model-Driven Development) (Margaria and Steffen 2008) introduced first with the jABC modeling framework (Steffen et al. 2006; jABC) and later in DIME (Boßelmann et al. 2016). The paradigm is summarized in the entry “eXtreme Model-Driven Development (XMDD) technologies as a hands-on approach to software development without coding” of this Encyclopedia ([Margaria and Steffen](#)). jABC is a framework for model-driven development of service-oriented applications. It provides an intuitive yet powerful representation of processes in terms of service

orchestrations (see Fig. 1) that use libraries of domain-specific building blocks as a reusable DSL. Applied to game strategies, this means that simple yet immediately functional and nontrivial example strategies can be created from a taxonomy of pre-defined domain-specific building blocks. In this entry they concern games, but other domains in use include scientific workflows in bioinformatics, business processes, text analyses in computer linguistics, healthcare processes, workflows in smart manufacturing, and several industrial applications in projects. After instantiation, each such component can be parameterized depending on the current context of use.

ConnectIT

ConnectIT (Bakera et al. 2009) was developed in 2008–2010 using jABC and repeatedly used in week-long CS summer camps with school pupils (grade 10–12), to teach computational thinking by means of strategies for the well-known connect-four game: Two players throw in turn a token in a board of seven columns and six rows. The token falls down to the lowest unoccupied position in the column. Each player plays with its own token color. The player that gets a group of four connected tokens (either horizontally, vertically, or diagonally) wins the game. The game is drawn when the board is full and no player won.

Strategies for this game were first studied by Allis (1988), who followed a knowledge-based approach. In ConnectIT, it is deliberately not possible to build the perfect strategy identified by Allis. Instead, the provided building blocks allow for the construction of strategies that analyze patterns on the board, and the goal for the students is to build the best (imperfect) strategy to win the competition with their peers.

Figure 1 shows a simple and intuitive yet powerful representation of a strategy called *Average Joe*: It will give preference (expressed by a higher score) to cells that already have tokens of the same color nearby, thus increasing the chance of getting four in a row. Technically, the strategy is an orchestration of services that are the building blocks of a ConnectIT DSL. Once a strategy is created, having a measure at hand that allows for both concise and easy evaluation and comparison of several strategies offers two benefits:

- 1. First, a fast validation technique of the overall outcome reveals errors at an early development stage.
- 2. Second, the learning curve to become comfortable with the strategy under development is greatly improved – since strategies’ behavior and impact depend on highly context-sensitive fine-tuning of parameters.

Modeling of Games and Game Strategies,

Fig. 1 A simple strategy for ConnectIT (“Average Joe”). (From Bakera et al. 2009)

Modeling of Games and Game Strategies,

Fig. 2 Evaluation of a ConnectIT strategy and snapshot of the tournament model. (From Bakera et al. 2009)

In the connect-four game, considering the adversary's possible moves additionally to the own ones also requires deciding which (relative) weight this information carries in the decision of the next move. Accordingly, ConnectIT provides an integrated evaluation functionality of the strategies and of their parametrizations in terms of tournaments. The effects can be studied in depth by playing several different kinds of tournaments (round robin, everyone against everyone, direct elimination, etc.) with (virtual) users that adopt the one or the other strategy. Each tournament returns a graphical presentation of the results (see Fig. 2 for a snapshot) and details about each match in the tournament. Combining several evolution steps in strategy development into a tournament enables students to directly witness and quickly pinpoint the effects of the decisions taken and to improve their strategy. This capability directly reveals whether a supposed enhancement of the strategy also yields a significant improvement of the strategy's competitiveness.

ChainReaction: Computing Camps for Girls

Increasing the number of female students in ICT-related university courses has been a major concern for several years. In 2015, McInerney et al. offered for the first time a girls-only computing summer camp, as a new component in the education and outreach activities to foster students' interest in computer science (IEEE 2016; McInerney et al. 2017). Two 3-day camps for

postprimary girls aged 14 and up were ran during the summer of 2015 at the University of Limerick. In the schedule for 3 days, the development of game strategies for the ChainReaction board game occupied ca. 2 days, including the students' final presentations. The other sessions were devoted to invited speakers from the industry and academia and to a robotics session with the NAO robot.

Modeling executable strategies for the ChainReaction board game was a major component of the program (blue sections in the table). ChainReaction (<http://chainreaction.freewarepoint.de>) is a strategy game for two players, who play against each other on a special 6x5 board, both trying to initiate chain reactions of atoms to conquer the whole board and win the game (see, e.g., the "Introduction to ChainReaction" page (<https://hope.scce.info/chainreaction/>) for a detailed description of the rules). The development of the game strategies to be followed by a computer player takes place in a specially prepared version of the jABC modeling framework (Steffen et al. 2006; jABC), which supports the intuitive, graphical development of flow-graph structures to define the behavior of a system. Figure 3 gives an impression of how the modeling of ChainReaction strategies with jABC works: The component library on the left contains the building blocks from which the strategies are assembled. The strategies focus on defining how the score for a cell on the board is to be computed.

Modeling of Games and Game Strategies, Fig. 3 The ChainReaction game, modeling of ChainReaction strategies with jABC, and results of a tournament played between nine strategies

The framework then evaluates the strategies for all cells and places the next atom into the cell with the highest score (or, if there are multiple cells with the same highest score, randomly choosing one of them).

The framework, which is very similar to the successful jABC version for the modeling of game strategies for the more popular ConnectIT board game described earlier in this entry, combines an easily accessible application domain with a quick sense of achievement: The first game strategies are typically ready to run after a 30-minute introduction to the modeling tool. Students can then work on incrementally improving this starting strategy. They also get immediate feedback about the quality of the results by playing against their own strategies or by letting the strategy play against other computer players. As such, it provides a very motivational framework and a fun and lightweight learning-by-doing way to acquire and practice computational thinking skills.

In the first camp session, participants were introduced only to the basic ChainReaction game and had some time to play and familiarize themselves with it. The girls paired up on one computer for this exercise and worked together in these pairs for the rest of the camp.

The next session was designed to foster more strategic thinking about the game. The task for the girls was to write down – simply on paper – how they had actually played the game, that is, which strategy they had followed to decide where to place their atoms. The groups then exchange strategies on paper, and each group tried to play strictly according to what the other group had written down. In a very entertaining way, this demonstrated the importance of formulating precise and unambiguous instructions.

The last session of the first day introduced the modeling tool and taught students how to model and execute their first simple ChainReaction strategy. The remainder of this session and the ChainReaction sessions on Day 2 were focused on the development and improvement of game strategies. At various intervals additional hints and suggestions helped the girls improve their strategies, which became quite sophisticated toward the end of the second day.

In the last ChainReaction session, on the third day, every group had to select and submit their final strategy. They entered a final tournament with all strategies playing against each other to determine the best one. The bar chart in Fig. 3 (lower right) shows the results of a tournament of nine strategies.

Modeling of Games and Game Strategies,

Fig. 4 Serious games in Second Life: business processes and workflows act in the virtual 3D experience

Serious Games: The Potential for Business Applications

The development of strategies and strategic behavior is most relevant to entrepreneurs or management teams that have a clear vision and mission for their business and are in the process of developing primary strategies. The development of a suite of strategies is an iterative process and involves circular thinking on the basis that optimal strategies will evolve gradually and be very interdependent. Accordingly, the best way to test strategies is to define, model, and test them. By applying the ConnectIT approach to simulate business-related strategies, entrepreneurs and managers can easily evaluate their strengths and weaknesses in strategic planning and behavior (Fig. 4). Additionally under virtual conditions, the learning process for the managers and entrepreneurs is risk-free and costless. Furthermore, the results of a chosen strategy can be analyzed systematically and improved over time.

A venture is most prone to failure during its first three or so years of operation – the so-called valley of death (Murphy and Edwards 2003).

A key to getting through these early years is to avoid the obvious mistakes. Generally speaking, businesses fail for significant and substantial reasons which are often very evident to outsiders. Insiders often fail to see them because of their closeness, determination, and so on.

These issues were reflected by the project *Science in 3D* (Lattemann and Stieglitz 2008) at Potsdam University. It employed a virtual world environment, Second Life, as an innovative tool for knowledge transfer for train entrepreneurs in the sector of biosciences. virtual worlds enable, thanks to their 3D environment, new ways of communication, collaboration, and cooperation. The level of interactivity of virtual worlds is higher compared to other web applications based on plain text, voice, or 2D presentations. Users in virtual worlds are represented by 3D avatars.

In this 3D training camp, entrepreneurs had to go through the whole cycle of a venture including selling products to customers. As Second Life had at that time a quasi-real economy, with an own currency and about 100,000 visitors daily who may act as customers, entrepreneurs could

easily test their venture skills. The central part of this educational experience was the phase of “managing, growing, and ending the new venture.” This phase includes the development of entrepreneurial strategy in the field of generating and exploiting new entries, growth strategies, and strategies for accessing resources and so forth (Hisrich et al. 2005). The project intended to provide simulations of the development of these kinds of strategies by implementing a ConnectIT-like approach for these strategies on a 3D basis in the virtual world. The one-thing approach to business process modeling in the jABC (Margarita and Steffen 2009) made this transfer to the business context easy and intuitive.

Discussion/Evaluation

If schools are offering “computers,” what is taught in schools varies widely and can include HTML/web design, ECDL, browsing the web, typing, Scratch, GIMP, as well as working with Microsoft Word and Excel.

Quick Start and High Productivity

Model-based games like ConnectIT and ChainReaction combine an easily accessible application domain with a quick sense of achievement: The first game strategies are typically ready to run after a 30-min introduction to the modeling tool. Students can then work on incrementally improving this starting strategy. They also get immediate feedback about the quality of the results by playing against their own strategies or by letting the strategy play against other computer players. As such, the XMDD-based approach to games provides a very motivational framework and a fun and lightweight learning-by-doing way to acquire and practice computational thinking skills.

Note that the ability to be productive quickly is an essential trait mentioned when choosing scripting and interpreted programming languages like Python, PHP, or Lua over traditional programming languages like C, C++, or Java. The perceived simplicity of the language and the

resulting improved confidence of the students are essential to avoid frustration due to struggle with complex environments.

In these applications of XMDD, the students end up mastering the essential concepts of a programming language through the domain-specific language of the game and are free to concentrate on the strategy design rather than on coding-level issues.

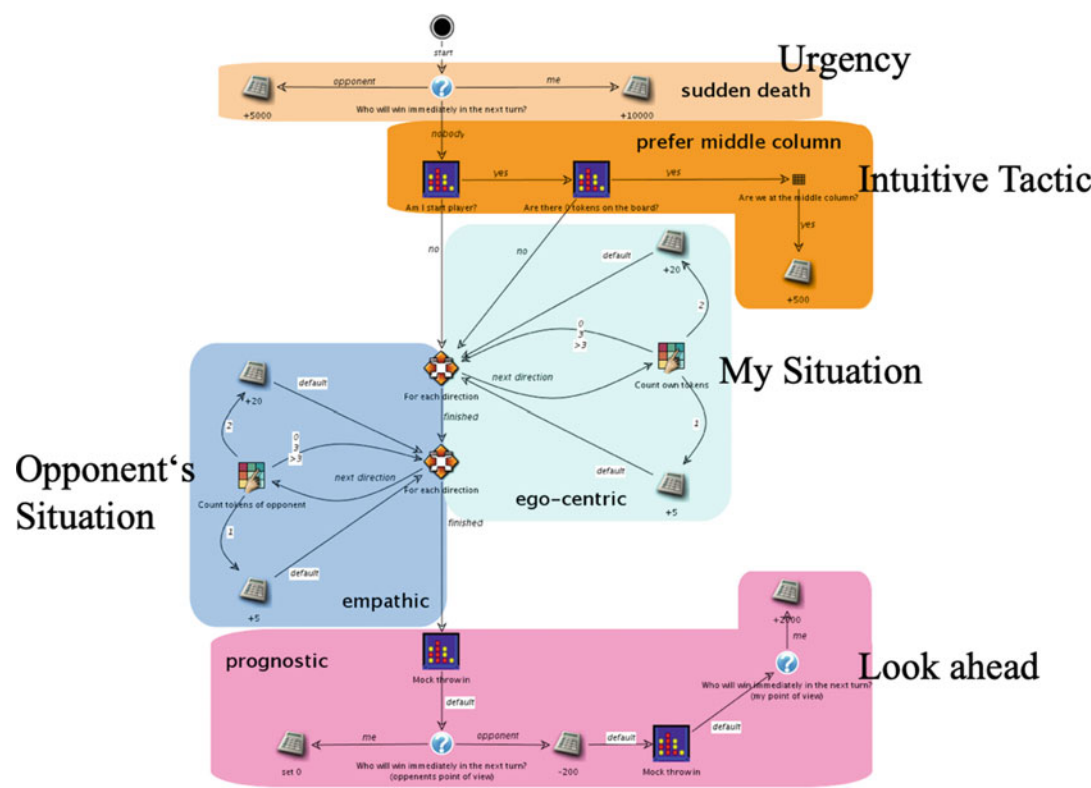

Ability to Express Complex Strategies

ConnectIT was used and refined in several rounds of the Do-Camp-Ing initiative (**Do-Camp-Ing; ConnectIT**) and in 1-day workshops (“Schnuppertage”) (<http://connectit.cs.tu-dortmund.de/blog/>), with heterogeneous groups of pupils who had no previous computer science training.

The pupils were able to build really competitive strategies like the one shown in Fig. 5 just by leveraging their intuition and knowledge about the connect-four game.

The *Chaos AI* strategy (name chosen by the two pupils who developed it) is very competitive. It contains the *Average Joe* component but adds a defensive part which considers the opponent’s tokens. Furthermore, *sudden death* initially checks whether a throw in the current column leads to an immediate win. If so, it scores the column appropriately. Whenever there are no tokens on the board, the strategy *prefers the middle column*, a direct implementation of a rule of thumb (like the favored center position in the tic-tac-toe game) that emerges as a best practice when playing.

After counting the own and opponent’s tokens on the board, the *prognostic* part of the strategy explores the near future via a mock throw-in at the current column. The mock throw-in building block exchanges the roles of the player and opponent; thus, all subsequent building blocks must be treated from the opponent’s point of view (until another mock throw-in appears, as in our case). After the first mock throw-in, the strategy checks whether the opponent would win. In this case, one would help the opponent, so the score for the

Modeling of Games and Game Strategies, Fig. 5 Chaos AI: A ComplexStrategy (by pupils)

current column is 0. The other case is first punished with a moderate malus (−200 points), as one would build a too obvious triple that is likely to be blocked by the opponent. Second, another mock throw-in follows in this case (and the roles are switched again). If one would still win in this situation, the column gets a high score, as this indicates a catch-22.

Another approach for describing games in a concise manner was developed by the Stanford logic group and is termed game description language (Genesereth and Love 2005). Its main purpose is the description of games including the rules, the board, the players, and their interplay. However, the lisp-like notation of the language that in fact describes a state machine lacks in a graphical and understandable representation. For instance, a description of the connect-four game takes about 150 lines of code.

ChainReaction: The outcome of the tournament in the girls' camp is shown in Fig. 6. On average, the 24 strategies submitted to the final tournaments of the camps consisted of 19.16 building blocks (median 16, standard deviation 8.85) and had a McCabe number of 6.92 (median 7, standard deviation 4.13). The McCabe number (Murphy and Edwards 2003) gives the number of linearly independent paths through a process model and is commonly used quantitative complexity measure for software. That is, although not being very large, the submitted strategies were by no means trivial and contained

various decision/branching points that create complex program flows, which is reflected by the McCabe number. With regard to readability and maintainability, typically a McCabe number of 10 is considered to be the upper acceptable limit of a program's complexity. The average McCabe

Modeling of Games and Game Strategies, Fig. 6 ChainReaction: tournament results (from [WCCE])

number of the strategies is clearly below this threshold, indicating that they are indeed at a very comprehensible level.

- In the **serious games** context, originally the most important aspect was the ability to model what-if scenarios, more than the 3D enactment of the scenes. The models were used to express and test hypotheses, to examine the consequences of decisions, and to validate properties and “rules” of the strategic decision-making under consideration. Two lessons were learned from this experience:
- The avatars and the simulation engine of Second Life were intriguing but not powerful enough to offer a realistic total immersion experience. Today’s gaming engines are much better, and they are in fact supplanting dedicated simulators in a number of applications where augmented reality and an immersive experience play a role. A recent example is the remote action of a technician directing a local crew to perform maintenance operations on equipment.
- Modeling of the business decisions and strategies was useful and valuable also

independently of the virtual world experience. In fact a new line of application of models was born from this experience, concerning the design and evaluation of business models (Boßelmann and Margaria 2014) using wizards to “direct” and guide the business user. Most recently this has evolved into a methodology for customization through knowledge sharing and configuration within enterprises (Steffen et al. 2016) and to systematically support decision-making through the hierarchical integration of heterogeneous business models (Steffen and Boßelmann 2018).

Impact of the Camps: Academic Exposure/ Career Perception

In order to evaluate and assess the impact of our camps, we administered surveys at the beginning and at the end of the camps.

At the beginning students were asked if they had ever written a computer program. Fifty-one percent stated they had not written a computer program before, 26% of participants had written a computer program, and 23% did not know if they had written a computer program. As Fig. 7 shows, the participants’ perceived ability to know

Modeling of Games and Game Strategies,

Fig. 7 Survey results on “I know how to program computers”
(ChainReaction)

how to program computers clearly increased between pre and post survey. Similarly, in our post survey, 95% of the students agreed and strongly agreed that they know more about computing as a job because of the camp. After the camp, we also asked the participants what they liked best about it and why, what they liked least and why, and what changes they would make to make it better.

One female participant in the mixed camps said: “I love the experience and the people even though we were split up in to groups and I was the only girl in the group I still made friends.” Interestingly, when this student was asked about what she liked least about the mixed camps she said: “I didn’t dislike most things the only thing I would change is putting at least one other girl into the group that I was in.” This suggests that the young girls simply might feel uncomfortable being the only female in a group, and female-only or better balanced mixed-gender groups make them feel more comfortable.

Based on the participants’ responses to the questionnaires, the girls-only camp was a very positive experience for them. Students’ self-perception that they are good at computing and their perceived ability to know how to program increased by the end of the 3-day camp. In terms of the perception of computing as a career, participants knew more and were more positive about the field as a result of the camp. The answers to the survey questions also align well with the instructors’ impression that the students had an enjoyable time while at the same time confirming that they learned a lot. The enthusiasm of the students can also be viewed in the video that was

created from footage shot by the students on the last day of the camp ([Google RISE](#)).

The Google RISE funding award for the girls-only camp enabled specific actions to raise awareness about underrepresentation of females in particular.

Conclusions and Outlook

The development of specific offers for secondary school students has become a substantial part of universities’ outreach and science communication activities in the last years. In order to be successful, they need to address attractive (or even fun) topics, which at the same time enable the students to learn something that is usually not part of their curricula.

A game-making project can significantly influence male and also female learners’ attitude to computing (<https://www.tandfonline.com/doi/full/10.1080/08993408.2013.774155>). A structured approach to training open-ended problem-solving can be of fundamental importance to nurture an independent but methodologically sound problem-solving (<https://ieeexplore.ieee.org/document/7344088/>), and the use of concrete tasks, for example, using LEGO Mindstorms, to engage students on algorithm design has proven successful for a long time (<https://ieeexplore.ieee.org/document/6685052/>). Games are more abstract, yet they typically make attractive course topics for students of all ages (IEEE 2014). They are also very suitable to address various aspects of software development, for instance, by looking more systematically at their mechanics, as we do with

the development of strategies for computer players. The ConnectIT and ChainReaction workshops combine an easily accessible application domain with a quick sense of achievement: the first game strategies are typically ready to run after less than 30 min after the introduction to the jABC tool. Students can then work on incrementally improving this starting strategy. The students also get immediate feedback about the quality of the results by playing against their own strategies or by letting the strategy play against other computer players. Summarizing, it is a very motivational framework that provides a fun and lightweight way to acquire and practice computational thinking skills.

Concerning ConnectIT, this experience was extended to an interdisciplinary project in the project/seminar “Strategies in virtual worlds” for students and graduate students of CS, business and management, and biology at the University of Potsdam. There, ConnectIT was reinterpreted as a platform for strategy definitions and enactment in virtual worlds:

- Integrated in the Potsdam Second Life platform ([Lehre in Virtuellen Welten](#))
- Applied as a 3D hands-on simulation environment of business, marketing, and communication strategies for founders of start-up companies – here mostly with a background in biology and life sciences, i.e., neither IT nor economy experts ([Science in 3D – BMBF-Projekt](#))

Further editions and variations of the computing camp in the future also include a camp for secondary school teachers, training them to use the tools in their computing classes. Dedicated OER (open educational resources) artifacts in multiple languages are going to make it easier for third parties around the world to carry out similar courses. The software, documentation, and basic tutorials are already freely available (mostly in English, partly in German). Their systematic multilingual preparation and the development of additional material, like detailed lesson plans for school teachers or video tutorials in

different languages, are ongoing. A first version was released into the Multimedia Education Resources for Learning and Online Teaching (MERLOT).

Introduction

In the age of big data, scientists of all disciplines need to become data scientists to analyze increasing amounts of research data. Often the available standard software is not sufficient for specific research purposes, so that the development of own, purpose-specific software becomes necessary. Hence, computational thinking, programming, and software development skills are not only taught in computer science and closely related study programs anymore but increasingly to students of all disciplines (Marshall 2017).

Many of the software applications that (data) scientists develop for their work are however not written from scratch. Rather, they reuse existing computational components such as programming

libraries, web services, and command-line tools and combine them anew for the specific purpose. The applications hence “orchestrate” components, by defining the execution order of the components and the flow of data between them. Over the last years, the scientific community coined the term *scientific workflows* to refer to scientific software applications with these characteristics. Scientific workflows can be implemented with standard programming languages, but dedicated *scientific workflow management systems* provide specialized support that simplifies their development.

Programming scientific workflows is in fact taught in many basic programming courses for (data) scientists, although this term is mostly not explicitly used and typically no clear distinction is made from other kinds of applications. Still, the most popular languages in data science today, namely Python and GNU R, are primarily used for the implementation of data analysis scripts and pipelines, which are essentially scientific workflows. In these courses, students face two challenges at the same time: they have to learn the basics of programming in a conventional text-based language, and they have to learn how to translate a data analysis problem into a workflow that solves it. So they face at the same time programming, in a bottom-up fashion from the code level, and problem-solving task in the domain of discourse, this time top-down from a conceptual level. Research has shown that it is often more effective to teach computational thinking skills at a conceptual level separately from teaching concrete coding skills, hence the combined teaching of both skills in one course can be regarded as undesirable.

Scientific workflow management systems free workflow developers from having to deal with the technical and syntactic details of a conventional programming language. The term *modeling* is typically used for describing the process of developing scientific workflows with such systems, emphasizing that implementation-level details do not matter and that modeling is not programming. Workflow models provide a level of abstraction that allows students to focus on the workflow on a conceptual level. In most systems,

the workflow models are represented as easily readable graph structures that can be built and manipulated in interactive graphical user interfaces. This way, workflow management systems are ideally suited to teach scientific workflows independently from teaching a concrete programming language.

This entry presents and discusses three selected examples of full-term STEM courses described in recent literature that use modeling of scientific workflows as a teaching tool (Section “[Modeling of Scientific Workflows as a Teaching Tool: Examples](#)”). It then discusses their commonalities and differences with regard to the educational context in which they are used (Section “[Discussion](#)”). Section “[Conclusion and Outlook](#)” concludes the entry with a summary and perspectives for the future.

Modeling of Scientific Workflows as a Teaching Tool: Examples

Modeling scientific workflows with dedicated workflow management systems instead of implementing them with conventional programming languages focuses the attention of workflow developers on problem-solving and understanding and managing the domain-specific essentials of the workflow instead of on the technicalities of code. Consequently, scientific workflow management systems are increasingly popular among researchers of all disciplines. They are also increasingly used in computational science education to teach students how to design and validate scientific workflows independently from teaching them about programming. Not much literature is available yet on this topic, so it is still difficult to quantify and give a systematic picture of their use in educational practice. This entry reports on three examples of workflow management systems that have been used as modeling tools to teach scientific workflows, for which detailed accounts can be found in recent literature: the jABC modeling framework (Steffen et al. 2007), the VisTrails environment (Callahan et al. 2006), and the WINGS workflow system (Gil et al. 2011).

Teaching Scientific Workflows with jABC: Agility and Intuition

The Java Application Building Center (jABC) (Steffen et al. 2007) (<http://jabc.de>) is a domain-independent, multipurpose modeling framework that follows the paradigm of eXtreme Model-Driven Development (XMDD). Its predecessors date back to the mid-1990s, with the more recent releases developed by the Chair for Programming Systems at TU Dortmund University, Germany. Stemming from a context of applied formal methods, jABC has always put an emphasis on the integration of functionality for formal verification and correctness-by-construction into the application development process. The workflow models used by jABC, so-called Service Logic Graphs (SLGs), are at the same time executable control-flow graphs, as shown in Fig. 1, and also Kripke Transition Systems that can be processed by formal verification tools like model checkers. Figure 1 gives an impression of jABC's user interface during workflow execution.

From 2006 onwards, jABC has been used as a scientific workflow management system in different applications areas (Lamprecht et al. 2016), and for several years as a tool to teach scientific workflows in the scope of a “Computer Science

for Natural Scientists” course at the University of Potsdam, Germany (Lamprecht and Margaria 2014, 2015). The participants in these courses were Master students from the “Bioinformatics” and “Geoinformation and Visualization” study programs, who had little or no prior education in computer science or programming. However, they came with domain-specific knowledge from their undergraduate program and were thus able to identify relevant data analysis problems from their domains. During the course, they learned how to model executable workflows for their chosen data analysis problems with the jABC framework. Their tasks involved the definition of the overall process flow, the identification and integration of components for the individual steps, the implementation, testing, and execution of the workflow with actual data, and finally their publication accompanied by a project report. The student projects of 2012 have even been published in a collective Springer volume (Lamprecht and Margaria 2014), where they form a gallery of diverse applications of scientific workflows in education. In 2015, the course was renamed to “Process Modeling in Scientific Applications” and extended to also allow computer science students to participate. Interdisciplinary pairs

Modeling of Scientific Workflows, Fig. 1 jABC (version 3.7), showing a workflow for LCMS data preprocessing and analysis with the Bioconductor xcms

package (<https://bioconductor.org/packages/release/bioc/html/xcms.html>) being executed

subsequent years, also at other places, for example, at the Universities of North Carolina, USA, and Linköping, Sweden. Thirty students participated in the first edition of the course in 2007. As detailed in (Silva et al. 2011), they worked with a number of different data sets and were given six different and increasingly complex visualization assignments to be done with Vis-Trails. Instead of just the final visualization, their submissions included the complete provenance trace of their projects, enabling more comprehensive assessments of the learning process and the results.

The student reviews of the course were reported to be very positive. Lecturer observations and student feedback agreed that the simplified construction of pipelines and the detailed change-based provenance mechanism in VisTrails had a positive effect on learning about data visualization processes. They experienced a streamlined exploratory process and enhanced interactions between students, course instructors, and teaching assistants. The tree-based representation of the provenance makes it easy to jump back to previous versions, undo changes, and compare different workflows, facilitating the incremental discovery and in-depth discussion of various possible solutions. In addition to supporting the students' exploratory data analyses, it helps lecturers to develop better teaching strategies based on the observations they can make about how the students proceed and how different people might approach the same problem.

Teaching Scientific Workflows with WINGS: Semantics and Distribution

The Workflow INstance Generation and Specialization (WINGS) framework (Gil et al. 2011) (<http://www.wings-workflows.org/>) is a project lead by researchers of the Information Sciences Institute of the University of California, USA. Now a system on its own, the underlying ideas have been developed in a variety of contexts since 2003. WINGS is advertised to be a semantic workflow system, meaning that it uses semantic information about data sets and workflow

components to assist scientists to create correct and executable workflows. The workflows can be submitted to a number of different distributed execution environments.

In “Teaching Parallelism Without Programming: A Data Science Curriculum for Non-CS Students” (Gil 2014) and “Teaching Big Data Analytics Skills with Intelligent Workflow Systems” (Gil 2016), Gil et al. describe a course where WINGS workflows are used to provide students with practical experiences with parallel and distributed execution. In contrast to the way parallel computing is traditionally taught – as part of a computer science curriculum and relying on advanced programming skills – the course is deliberately targeted at nonprogrammers, assumes no programming skills and does also not aim to teach any programming. Instead, it uses WINGS workflows to teach the concepts above the level of a concrete programming language. Students can use predefined workflows and workflow components to build and test their own applications.

A pretest run of teaching the course to a small group of students is reported to have been successful. The students in the test group had no or almost no knowledge of programming, but they found the material accessible, understood the concepts, and considered them to be useful. In particular, they appreciated that the abstract concepts were supplemented with practice that did not require classical computer science skills.

Discussion

Silva et al. (2011) state in the motivation for their VisTrails course that it was driven by the intuition that “the same features that support scientists in exploratory tasks would also be beneficial to students.” The same rationale underlies also the use of jABC and WINGS for teaching scientific workflows: the same features that support scientists in working with scientific workflows will also be a powerful scaffold for students. In fact, for all the courses sketched above, it is reported that their

perceived most important asset is that the use of their particular technology allowed the students to focus on their actual tasks, instead of having to deal with technicalities and implementation details on a programming-language level. Silva et al. even conclude that they “strongly believe that teaching is one of the killer applications” (Silva et al. 2011) of workflow technology.

Table 1 examines the concepts taught and competencies trained in the three courses in more detail. They form the essential part of the intended learning outcomes of the courses. Additional soft skills (like project management or presentation techniques) exercised in the courses are not included in the table. The concepts and competencies listed in the table were collected from the

publications that describe the courses. Note that these reports do not reflect the full capabilities of the respective systems, as not all their features were used in the described teaching contexts.

Computational thinking core. Some concepts and competencies appear almost inevitably in all three courses: Students learn about general and domain-specific data types, formats, and standards, and about the principal structure of data analysis processes (pre- and postprocessing and actual analysis). More technically, they learn to apply basic control flow structures (sequential execution, conditional branching, different forms of loops to control the order of the steps in a workflow, to manage the transfer of data between the computational components (depending on the

Modeling of Scientific Workflows, Table 1 Concepts taught and competencies trained in the different courses

system via a shared memory, by message passing, or both), and to organize complex workflows hierarchically making use of encapsulation and sub-workflows. They learn to execute workflows, monitor their execution, react on execution failures, and implement error handling behavior.

Agile solutions. The scientific workflow course taught with jABC let the students work on own, self-defined projects. As such, it put a particular emphasis on problem analysis and functional decomposition (students learned to analyze their problem from a computational perspective, and to identify the basic steps in the analysis and their order) and on prototyping and iterative refinement (workflows were first modelled with “dummy” components successively replaced with fully implemented and executable building blocks). Implicitly these appeared also in the other two courses, but as their focus was different, they played a less obvious role there. To implement their own projects, the students furthermore learned how to find and integrate computational components for the steps into jABC, and they were taught how to annotate and classify components and workflows in order to organize them in a systematic way. In the interdisciplinary version of the course, which was attended by computer science students as well, the students were furthermore shown how to apply the model checking and workflow synthesis features of the jABC for advanced workflow modeling support. These concepts and competencies did not play a noticeable role in the other two courses.

Visualization. The visualization course with VisTrails was naturally more focused on teaching principles of information visualization. Students used the system to practice and apply elementary plotting techniques, principles of aesthetics, 2D visualization techniques, and isosurfacing and volume rendering. Plotting of individual data sets with existing tools was also part of some of the workflows projects that were done with jABC, but the course did not actually teach concepts of information visualization.

Parallelism. The data science course with WINGS was designed to teach the principles of parallelism, which is also clearly reflected in

the table. In addition to general workflow modeling concepts and skills, students learn about complexity and run-time behavior of algorithms when executed with large sets of data and about the divide-and-conquer principle to split large complex problems into smaller, better tractable ones. The course furthermore explains and practices the principles of parallel, multicore, and distributed computing, as well as techniques for letting algorithms communicate across different processors.

Parallel and distributed computing also played a central role in the scientific workflow course taught with jABC: The workflow models support fork/join parallelism, which was indeed used by some of the students to represent naturally parallel strands of activities in their data analysis processes. More importantly, the integration of web services and other distributed resources was a key part in the students’ workflow projects with jABC. Although more generally and at a higher level of abstraction than in the WINGS-based course, principles of modern distributed computing were learned and practiced there too.

Conclusion and Outlook

Engaging STEM students with the modeling of scientific workflows has proven to be an effective teaching tool for training their competencies in dealing with computational data analysis challenges from all disciplines of science. With the ongoing further development and evolution of scientific workflow management systems, learning to program in the traditional sense might become in the future completely unnecessary for the many scientists who use algorithms and tools in flows, and do not develop algorithms and infrastructure software themselves. As evident from the three programming-free courses discussed in this entry, the skills that are needed to solve domain-specific problems are above the level of concrete programming languages. Students’ learning of the course topics benefits greatly from not having to deal with code-level technicalities.

Modeling the Process of Information Technology Innovation in Education

Arthur Tatnall

Victoria University, Melbourne, VIC, Australia

Synonyms

[Education](#); [Information technology](#); [Models of technological innovations](#); [Technological innovation](#)

Introduction

Change occurs in all forms of education, but particularly in relation to adoption of new information technologies. New ideas, new approaches, and new technologies frequently appear in classrooms at all levels from pre-school to university. This entry looks at the processes by which new technologies in education are adopted and used in the form they were offered, partially adopted, or rejected completely. This process is known as innovation and, rather than involving the *creation* of new technologies, describes the process of *adopting* and putting these technologies into practice (Maguire et al. 1994).

To investigate if and how new information technologies are adopted in education, it is useful to consider one of the theories of technological innovation:

- The linear model of innovation
- The diffusion of innovations
- The theory of reasoned action (TRA)
- Social cognitive theory (SCT)
- The theory of planned behavior (TPB)
- The decomposed theory of planned behavior (DTPB)
- The technology acceptance model (TAM)
- Augmented TAM (or combined TAM and TPB)

- TAM2
- The unified theory of acceptance and use of technology (UTAUT)
- Innovation translation (informed by actor-network theory)

A description of these models used in the investigation of technological innovation and adoption in education follows.

The Linear Model of Innovation: Traditional Phase Gate Model

This very early innovation model suggests that technological change occurs in a linear manner beginning with invention and moving via innovation to diffusion (Godin 2006; Wikipedia 2017) (Fig. 1).

The innovation process is seen to proceed through a series of phases arranged such that a given phase must be achieved before moving on to the next and after passing through a gate with the permission of a gatekeeper. This model is offered in two forms as either “technology push” or “market pull.” The linear model of innovation has been heavily criticized due both to its linearity and to not taking note of any feedback loops.

Diffusion of Innovations

Rogers’ (1995, 2003) theory is well known. Rogers describes diffusion of innovations as: “. . . the process by which an innovation is communicated through certain channels over time among the members of social systems. It is a special type of

communication, in that the messages are concerned with new ideas” (Rogers 1995: 5). A decision to adopt an innovation relates to the acceptance of the new idea while a decision *not* to adopt relates to the rejection.

Rogers distinguishes between two kinds of information: *software information*, which is embodied in the technology (or idea) itself, and *innovation-evaluation information*, which relates to an innovation’s expected adoption consequences (Rogers 2003). Diffusion is thus considered to be a process of information exchange by the need to reduce uncertainty and relating to a communicating social network. In the diffusion process, Rogers considers the main elements to be the following.

Characteristics of the Innovation

To explain the rate of adoption of innovations, Rogers suggests consideration of the following perceived characteristics of innovations (Rogers 2003):

- **Relative advantage** – or the degree to which an innovation is perceived as better than the idea it supersedes. Relative advantage is often expressed in terms of economic profitability, social prestige, or other similar benefits. Rogers contends that an innovation’s relative advantage is positively correlated with its rate of adoption.
- **Compatibility** – the degree to which an innovation is perceived by potential adopters as being consistent with existing values and past experiences. Compatibility with what is already in place makes the new idea seem less uncertain, more familiar, and helps to give it meaning. This is important because “the rate of adoption of a new idea is affected by the old idea that it supersedes” (Rogers 1995: 227). Rogers argues that if an innovation is perceived to be compatible with what is currently used or done, this will increase its rate of adoption.
- **Complexity** – the degree to which an innovation is perceived as difficult to understand and use. Rogers claims that the more complex the innovation, the less likely it is to be quickly adopted. In support of this conjecture, Rogers

Modeling the Process of Information Technology Innovation in Education, Fig. 1 The linear model of innovation

et al. (1980) point out that in the late 1970s, a period of 6–8 weeks of extreme frustration characterized the adoption of a new home computer!

- **Trialability** – the degree to which a particular innovation may be subjected to limited experimentation. If “playing” with the innovation is possible, adoption is more likely.
- **Observability** – the more the results of an innovation are visible to everyone, the more likely the innovation is to be adopted.

Attributes of the potential adopter, including social status and education, are also seen as important. A slightly different slant on adoption is offered by Abrahamson and Rosenkopf (1993) who describe what they call the “bandwagon effect” when people or organizations adopt innovations, not because of their technical properties, but because a large number of others have already done so.

Communications Channels

Acts of communication are a necessary part of any change process, and to reach a potential adopter, the innovation must be diffused through some communications channel (Tatnall 2005). Rogers argues that channels involving mass media are often the most rapid and efficient means of spreading awareness of an innovation, but that interpersonal channels are generally more effective in persuading someone to accept a new idea (Rogers 2003), and that interpersonal communication is more effective when it is between those who are similar in socioeconomic status and education.

Time

Innovations are not adopted instantly and Rogers suggests a five-step process involving:

- Knowledge – when an individual is exposed to an innovation’s existence
- Persuasion – the formation of a favorable or unfavorable impression
- Decision – an action that leads to adoption or rejection
- Implementation – the innovation is put into use
- Confirmation – seeking reinforcement of an innovation-decision. “Have I made the right decision?”

He then classifies people in terms of innovativeness as belonging to one of the following groups: innovators, early adopters, early majority, late majority, and laggards (Fig. 2).

The Social System

Diffusion is seen to occur within a social system where the social structure constitutes a boundary inside which the innovation diffuses. Rogers argues that the system’s social structure affects diffusion through the action of social norms, the roles taken by opinion leaders and change agents, the types of innovation decisions that are taken, and the social consequences of the innovation (Tatnall 2005). “*Technology is a product of society, and is influenced by the norms and values of the social system*” (Rogers 1995: 139). Innovation Diffusion thus accepts concepts from the social construction of technology, and is based on the idea that technology is shaped by social factors.

Modeling the Process of Information Technology Innovation in Education,
Fig. 2 Categories of adopters. (Adapted from Rogers 1995: 262)

The Theory of Reasoned Action (TRA)

Fishbein and Ajzen (1975) developed the theory of reasoned action in 1975, before later comprehensively refining it with empirical evidence to support its validity and reliability (Ajzen and Fishbein 1980). In developing this theory, they made use of various studies on attitude from social psychology in order to develop an integrated conceptual framework to predict and explain an individual's behavior in a general setting. They postulated that beliefs influence attitude and social norms which in turn shape a behavioral intention guiding or even dictating an individual's behavior. They focused on three major determinants of an individual's behavior: behavioral intention, attitude, and subjective norm. In summary, they postulated that:

- An individual's behavioral intention is the immediate determinant of behavior.
- Attitude and subjective norm are mediated through behavioral intention.
- Behavioral and normative beliefs are mediated through attitude and subjective norm, respectively.

Although TRA gained wide acceptance in the behavioral sciences, the likelihood that a person will actually perform the specific behavior described has been questioned by many researchers (including: Warshaw and Davis (1985) and Davis et al. (1989)). In a situation where there is a gap between behavioral intention and actual behavior, some studies have found a low correlation between these two (Bonfield 1974; Harrell and Bennett 1974).

Social Cognitive Theory (SCT)

Developed by Bandura (1986), SCT suggests that human functioning should be viewed as the product of a dynamic interplay of personal, behavior, and environmental influences. He argued that how people interpret the results of their own behavior informs and alters their environments and the

personal factors they possess which, in turn, inform and alter subsequent behavior. Social cognitive theory gives consideration to:

- Personal factors (cognition, affect, and biological events)
- Behavior
- Environmental influences

The Theory of Planned Behavior (TPB)

TPB was developed by Ajzen (1985, 1991) after the identification of problems with the theory of reasoned action. Ajzen's main criticisms of TRA were that it was designed to predict and explain behavior, or actions, based on the assumption that the behavior was under a person's own control. But as some behavior is directed by outside influences and is not under a person's own control, there might be problems due to the differences in other individuals' abilities and in external forces, and this may influence actual performance of the behavior. He argued that consideration should be given to the concept of behavioral control to overcome these volitional control problems. To achieve this, Ajzen extended TRA by the addition of another construct called *perceived behavioral control*. This refers to an individual's perception of the "... presence or absence of requisite resources and opportunities" (Ajzen and Madden 1986:457) required to perform the specific behavior.

Following TRA, the theory of planned behavior assumes that behavioral intention is a function of two determinants: the individual's attitude toward the behavior and the subjective norm within the social environment. Ajzen (1991) argues that the addition of perceived behavioral control is important as it is expected that this concept will illustrate the likelihood of success in performing the behavior, and it is expected that it will provide a measure of actual control. Its validity as a measure to predict the likelihood of achieving the target behavior will depend on the individual's capability (e.g., having the requisite opportunities and resources) to exercise

control over the specific behavior. This means that a person who believes that they have the resources and opportunities expects fewer problems in performing the specific behavior and hence perceives that they have complete control over the specific behavior.

The Decomposed Theory of Planned Behavior (DTPB)

DTPB, introduced in 1995 by Taylor and Todd (1995a, b) suggests that behavioral intention is the primary direct determinant of behavior, but that attitude toward behavior, subjective norm, and perceived behavior control are also important. They suggest decomposing attitudinal belief into three factors: perceived usefulness, perceived ease of use, and compatibility.

The Technology Acceptance Model (TAM)

The technology acceptance model was developed from TRA by Davis and his colleagues (Davis 1986, 1989; Davis et al. 1989; Davis and Venkatesh 2004). TAM assumes that a computer user normally acts rationally and uses information in a systematic manner to decide whether or not to adopt this particular technology in the workplace. Davis (1986) identifies major determinants of technology acceptance and specifies a basis for causal links between the technology’s *perceived*

usefulness and *perceived ease of use* along with the individual’s *attitude toward using technology* and *behavioral intention* to explain technology adoption (Davis 1986, 1989; Davis et al. 1989) (Fig. 3).

In TAM, the effects of external variables (including system characteristics, development processes, education, or training) on the intention to get someone to use the technology are mediated by *perceived usefulness* and *perceived ease of use*. TAM has strong behavioral elements which assume that someone using a computer acts rationally and uses any available information systematically in order to decide whether or not to adopt this technology. TAM assumes that when someone forms an *intention* to act, they will be free to act without any limits, and that they will do so. Perceived usefulness is influenced by perceived ease of use because if other things are equal, the easier the new technology is to use, the more useful it must be (Venkatesh and Davis 2000). TAM assumes that adoption and use of any new information technology is voluntary (Davis 1989), and that provided they have sufficient time and knowledge about the technology, their stated preference to perform the activity and their behavioral intention will determine the way in which they behave and how they will adopt the technology (Tatnall 2011).

TAM offers a theoretical basis for specifying the linkages between perceived usefulness and perceived ease of use in determining users’ attitudes, intentions, and actual information systems adoption behavior. Behavioral intention is jointly

Modeling the Process of Information Technology Innovation in Education, Fig. 3 The technology acceptance model (Davis 1986, 1989)

determined by attitude and perceived usefulness, while attitude is determined by perceived usefulness and perceived ease of use.

Augmented TAM (or Combined TAM and TPB)

TAM does not include the influence of social and control factors on behavior but those factors have been found by Taylor and Todd (1995a, b) and Moore and Benbasat (1991) and others, to significantly influence technology usage behavior. Taylor and Todd (1995a) developed augmented TAM by the addition of two factors to TAM: subjective norm and perceived behavioral control to provide what they saw as a more complete test of the important determinants of technology usage because of their predictive and wide use in social psychology (Kripanont 2007).

TAM2

Venkatesh and Davis (2000) developed TAM2 as a theoretical extension of TAM to include additional key determinants that explain perceived usefulness and usage intentions in terms of social influence and cognitive instrumental processes, and to understand how the effects of these determinants change with increasing user experience over time with the target system.

The Unified Theory of Acceptance and Use of Technology (UTAUT)

UTAUT was developed by Venkatesh et al. (2003) to provide a refined view of how the determinants of intention and behavior evolve over time in explaining IT usage behavior. UTUAT was developed from the theory of reasoned action, the technology acceptance model, motivational model, the theory of planned behavior, a combined theory of planned behavior/technology acceptance model, the model of personal computer use, diffusion of innovations theory, and social cognitive theory (Venkatesh et al. 2003). UTAUT offers

behavioral intention and usage behavior as two dependent variables in the model. It introduced four core determinants of intention and usage:

- Performance expectancy
- Effort expectancy
- Social influence
- Facilitating conditions (Fig. 4)

Attitude toward using technology, self-efficacy, and anxiety are theorized *not* to be direct determinants of intention to adopt and use. The key moderators identified in the model are gender, age, voluntariness, and experience (Kripanont 2007).

Innovation Translation (Informed by Actor-Network Theory)

A common approach to researching innovation in information systems is to focus on the technical aspects of an innovation, and to treat “the social” as the context in which its development and adoption take place (Tatnall 2007). The view of innovation proposed by actor-network theory (ANT), sometimes known as sociology of translations (Callon 1986b; Latour 1986, 1996; Law 1987), considers the world to be full of hybrid entities containing both human and nonhuman elements, and offers the notion of heterogeneity to help in the explanation of technology adoption (Tatnall and Davey 2003). Innovation translation (Callon 1986b; Latour 1996), informed by ANT, makes use of a model of technological innovation which uses ANT concepts, as well as the concept that innovations are often not adopted in their entirety but only after “translation” into a form that is more appropriate for use by the potential adopter.

In actor-network theory, the extent of a network is determined by actors that are able to make their presence *individually felt* (Law 1987) by other actors. Each actor is not just a “point object” but an association of heterogeneous elements, making up a network. An actor can, however, also be considered as a “black box” (Callon 1986a), containing other actors that we may not, at the moment, want to see or deal with. When we open the lid of the box to look inside, a whole

Modeling the Process of Information Technology Innovation in Education, Fig. 4 The unified theory of acceptance and use of technology (Venkatesh et al. 2003)

network of other, perhaps complex, actors and associations will appear. The value of the black box concept is that in many cases details of what constitutes an actor – details of its own network – are a complication we can avoid having to deal with at this time.

Callon (1986b) proposes that translation involves strategies through which an actor identifies other actors and places them appropriately in relation to each other. Latour (1996) speaks of how “chains of translation” can transform a global problem, such as the transportation needs of a city like Paris (or a new approach to obtaining appropriate software for the educational curriculum), into a local problem like continuous transportation (or how to introduce the concept of programming to Grade 3 students).

Latour (1996) suggests that with an innovation translation model, the initial idea counts for little, and unlike some of the other innovation theories, the innovation itself is not endowed with “autonomous power” or “propelled by a brilliant inventor,” but only moves if it is of interest to one group of actors or another (Tatnall 2009). Movement of the innovation is a consequence of energy given to it by everyone in the chain and when the

innovation does interest a new group, they transform it a little or perhaps a lot (Latour 1996: 119). Latour (1986) maintains that in the innovation translation model the movement of an innovation through time and space is in the hands of people, each of whom may react to it in different ways: they may modify it, deflect it, betray it, add to it, appropriate it, or let it drop. Here, instead of a process of transmission, we have a process of continuous transformation (Latour 1996) where faithful acceptance involving no changes is a rarity. “Instead of the transmission of the same token – simply deflected or slowed down by friction – you get ... the continuous transformation of the token” (Latour 1986: 286). Latour notes that, except in rare cases, there can be “no transportation without transformation,” and that “... after many recruitments, displacements and transformations, the project, having become real, then manifests, perhaps, the characteristics of perfection, profitability, beauty, and efficiency that the diffusion model located in the starting point” (Latour 1996: 119).

Suppose that some new technology has been developed and some person, group, or organization would like to get it adopted. Actor-network

theory asserts that the contributions of both humans and nonhumans (information technology in this case) need to be given equal consideration, so this person or group proposing the new technology is referred to by the term heterogeneous engineer. In explaining how this process works, Callon (1986b) outlines four aspects or “moments” in the process of translation:

1. *Problematization* involves the heterogeneous engineer defining the nature of the problem so as to be seen by other actors as having the answer.
2. *Interessement* involves interesting and attracting an entity by coming between it and some other opposing entity.
3. *Enrolment* occurs through a process of “coercion, seduction, or consent” and, if all goes well, leads to the establishment of a solid, stable network of alliances.
4. *Mobilization* locks in as the solution proposed by the heterogeneous engineer gains wider acceptance through some actors working to convince others.

Conclusion

In the case of adoption of new IT in education, which model is the most appropriate? This depends on the scale, complexity, and nature of the situation under consideration. Of the models that could be used in an investigation of information technology innovation and adoption, only three are now in serious use: innovation diffusion, UTAUT (incorporating TAM and several of the others), and innovation translation.

Innovation diffusion, as the name suggests, is useful for examining the large-scale spread, or diffusion, of innovations around a large area. When studying the international uptake of mobile phones, diffusion offers a useful approach. In education, the diffusion of the teaching of coding (programming) in schools is another situation where this approach would be useful.

The unified theory of acceptance and use of technology (UTAUT) is used mainly to examine the uptake of IT by businesses and other large

organizations. It assumes that the potential adopter has free choice in making the decision on whether or not to adopt, and concentrates on analysis of the human properties and actions involved.

Actor-network theory (ANT) considers the role of both humans and the technology (nonhumans) in the potential adoption. Innovation translation places equal importance on each and suggests that innovations are not adopted as is, but are first translated into a form suitable to the potential human adopter. For many situations in educational use of information technology where both people and the technology itself have an important role to play in the adoption, innovation translation offers a useful approach.

MOOCs, Teacher Professional Learning and Deep Learning Conversations

Deirdre Butler¹, Margaret Leahy¹, Michael Hallissy² and Mark Brown³

¹Institute of Education,

Dublin City University, Dublin, Ireland

²H2 Learning, Dublin, Ireland

³National Institute for Digital Learning,
Dublin City University, Dublin, Ireland

This entry describes an innovative model of teacher professional learning that has evolved over a decade (2006 to 2016). In particular, it explores how this face-to-face model of professional learning can be successfully reconfigured in an online environment to help scale up the initiative. Designed as a school-focused, job-embedded teacher professional learning framework that meets teachers' expressed needs, the model helps to shift teachers' pedagogical orientations and challenge more traditional instructional environments by embedding digital technologies and other elements of twenty-first-century skills into the teaching and learning experience. Building on the experiences of implementing this framework, this entry reports the most recent phase which attempts to harness the emergence of a 4th wave of online learning. This initiative involves the design and development of a Massive Open Online Course (MOOC) that potentially enables the massive scaling up of access to this already validated model of teacher professional learning. The importance of maintaining key elements, threshold concepts, and signature pedagogies in the design of MOOCs for teacher professional learning is discussed. The entry also explores some of the challenges and potential opportunities different MOOC delivery models offer for sustaining the types of collaboration, rich dialogue, and ongoing reflection observed in earlier phases of the project.

Introduction

Stated goals for the development of “21st century skills” include critical thinking and problem-solving, communication, collaboration, self-regulation, information management, and the ability to use digital technology effectively and reflectively (e.g., ETA 2010; OECD 2005; Binkley et al. 2012) and have become commonplace globally. There is growing consensus that both teaching methods and learning environments need to change to help students develop the skills they need to succeed in the twenty-first century (e.g., Ananiadou and Claro 2009). Despite this, past experience suggests teachers rarely have access to specific guidance or sufficient support on how to design learning scenarios which develops these skills in the classroom. Faced with this reality, the challenge is how to design professional learning experiences for teachers that enable them, in turn, to design learning activities so that their students can develop the dispositions, skills, and competencies that are required to live and thrive in this complex, globally connected world of the twenty-first century.

Against this backdrop, this entry describes an innovative model of teacher professional learning that evolved over a decade (2006 to 2017). It begins by describing the professional learning model for teachers which was designed and developed in a single secondary school in Ireland before being expanded district wide. The impact of this job-embedded program is outlined indicating the shift in pedagogical orientation and the resulting student learning. It then explores how this face-to-face model of professional learning can be successfully reconfigured in an online environment to help scale up the initiative while also being mindful of the importance of maintaining key elements, threshold concepts, and signature pedagogies in the design and development of the scalable model.

Background and Context: Teacher Professional Learning Model

Originating in Microsoft's “Innovative Schools Program” (ISP), the focus of the initiative was

the integration of digital technologies into teaching and learning in the postprimary sector, and the main objective was to design a model for teacher professional learning in a large Irish secondary school. This approach was considered particularly important in Ireland because rigid state standards and a traditional exam-based system of education at secondary level constrain teachers' ability to change their instructional practices. It leaves them with little time or flexibility to introduce new ideas or practices.

In developing a model for teacher professional learning, the lead authors (Butler & Leahy) realized the need not only to work closely with teachers and school management but also the importance of focusing on the teachers' beliefs and values as the starting point. This focus was based on research evidence that teachers' pedagogical orientations are a dominant factor in how they choose to use (or not) new technology in their classroom (e.g., Law and Chow 2008; Shear et al. 2011; Lawrence and Tar 2018). It follows from this line of research that professional learning programs are most effective when they are:

- (i) Embedded into teachers' professional lives and communities within the school (National Foundation for the Improvement of Education 1996)
- (ii) Focused explicitly on local goals for student learning (e.g., Darling-Hammond 1993)
- (iii) Grounded in collective discussions of classroom practice (Warren Little 2003)
- (iv) Anchored in active learning supporting collaboration and critical reflection over a sustained duration (Darling-Hammond et al. 2017).

Previous experience in developing a model of professional learning had also led to the realization that in order to change classroom practice, teachers need to ask questions about their existing classroom practices (Butler 2004). To this end, key features of the professional learning program were that it was directly related to the teachers' stated needs and experiences, anchored in the meaningful context of their own classroom practices and in particular, teachers were challenged to question their practice. The Learning Activity/Student Work (LASW) framework (see Table 1) developed by Stanford Research Institute (Shear et al. 2009) was used as a key feature of the professional development program developed as part of the ISP program in Ireland.

The framework was the catalyst that enabled the teachers to design learning activities in which they embedded twenty-first-century learning principles, develop the meta-language used to

MOOCs, Teacher Professional Learning and Deep Learning Conversations, Table 1 Learning Activity/Student Work (LASW) dimensions

Learning activity dimensions	Student activity dimensions
Collaboration: Are students required to share responsibility and make substantive decisions with other people?	Collaboration: Did the student share responsibility? Did the student make substantive decisions with other people?
Knowledge building: Are students required to build knowledge? Is that knowledge interdisciplinary?	Knowledge building: Did the student build knowledge? Was that knowledge conceptually accurate and interdisciplinary?
Use of ICT for learning: Do students use ICT to support knowledge building? Is ICT necessary to that knowledge building?	Use of ICT for learning: Were students passive consumers, active users, or designers of ICT?
Self-regulation: Is the learning activity long-term? Do students plan and assess their own work?	Skilled communication: Did the student produce extended communication? Was the communication well-developed and organized around a thesis?
Real-world problem-solving and innovation: Does the learning activity require solving authentic, real-world problems? Are students' solutions implemented in the real world?	Real-world problem-solving and innovation: Did the student develop a successful solution to a real-world problem? Did the student implement the solution in the real world?

describe such learning environments, as well as reflect on their teaching and the assignments they set their students (Butler and Leahy 2010, 2011, 2015). The professional development program was directly linked to a university postgraduate accreditation process.

Building on the success of Phase 1, the initiative was expanded to district level in Phase 2. In consultation with Butler and Leahy, management decided to invest funding into the professional learning of a key group of teachers in schools across the district. It was perceived that these teachers would become peer coaches and promote the creative integration and use of digital technologies in teaching and learning among teachers at their schools. The target group identified to become peer coaches were the ICT coordinators from schools across the district. Traditionally, the role of ICT coordinator was associated with ensuring that hardware was in working order or at best supporting the development of teachers' technical ICT skills. However, this role was redefined whereby ICT coordinators were now expected to support innovative and emerging new pedagogies and technologies to facilitate student learning and the development of twenty-first-century skills. The management also requested that formal accreditation would continue to be a feature of the program. In response, the Digital Learning Peer Coaching (DLPC) program was developed (c.f. Butler and Leahy 2015).

Impact of the Professional Learning Model

Across Phases 1 and 2, teachers, school leaders, and management initially tended to view digital technologies as tools to support traditional practices. However, through active participation in the program, their understanding shifted, and they began to perceive new technologies as tools that facilitate more progressive classroom practices and the development of their students' twenty-first-century skills. Evidence of this change and enhanced quality of education are found in the national evaluation reports of the ISP as well as through analysis of the coursework and final dissertations produced by teachers participating in the postgraduate diploma (Butler

and Leahy 2015). Together, they demonstrate that the overriding impact of the program was to move teachers "out of their comfort zones" (Butler and Leahy 2015). It enabled the participating teachers to design learning environments which were more student-led and characterized by the use of a range of digital technologies supporting an enquiry process that demanded the use of essential skills such as knowledge construction, problem-solving and innovation, self-regulation, skilled communication, and collaboration. This was evident by the emergence of the following trends in classroom practices:

- Student-centered learning
- Project-based learning rather than discrete lesson plans
- Students working collaboratively in groups rather than individual learning
- Focus on learning not on subject "content"
- Awareness of designing lessons with opportunities for students to develop twenty-first-century skills
- Increase in teacher confidence to use a greater range of pedagogical strategies/digital technologies
- Collaboration across and between subject departments (i.e., ripple effect)

The shift in pedagogical orientation along with increased use of digital technologies in learning and teaching had a positive impact on student learning, resulting in learners:

- Taking more control of their own learning
- Having greater ownership of the learning activities
- Demonstrating more engagement/participation
- Increased collaboration
- Being active rather than passive in their learning
- Taking on new leadership roles

The Issue of Scalability

Although the developments and findings outlined above were encouraging, the issue of scalability has become increasingly problematic. Policy decisions in relation to the development of

a range of “21st century skills” (NCCA 2009), as well as the ability and the need to use digital technology effectively and reflectively in schools in Ireland, led to ongoing demands to extend this model of professional learning. In particular, the launch of the Digital Strategy (DES 2015) in Ireland identified “a need to ensure that ALL teachers are equipped with the knowledge, skills and confidence to integrate ICT into their practice” (p. 7). As a way of addressing the issue of scalability, the possibility of using an innovative MOOC format was considered in the wider context of the emergence of a 4th wave of online learning (Picciano 2014) which builds on the principles and foundations of blended learning.

MOOCs as a Possibility of Scaling the Model of Professional Learning

Research literature suggests that MOOCs have been most successful for those who already hold an undergraduate college degree or higher (e.g., Ebben and Murphy 2014). While MOOC completion rates are low, prior level of schooling is a predictor of achievement in MOOCs (Greene et al. 2015), thus suggesting that teachers completing a MOOC for professional learning might be more likely to complete it than other participants (Hodges et al. 2016). In fact, Laurillard (2016) considers the use of a MOOC as a medium for the continuing professional learning of teachers as “a perfect fit” (p. 7). Misra (2018) supports this view and argues that MOOCs “can be a cost and resource effective means to complement the traditional methods of professional development of teachers” (p. 67). Therefore, coupled with the growing number of open solutions targeting schools (e.g., ICEF Monitor 2016; Vivian et al. 2014), it was a logical step to investigate the use of a MOOC to scale the model of teacher professional learning that had been developed.

The Many Guises of a MOOC

MOOCs are now recognized as a valid form of professional learning in a number of professions. For example, in 2014 in Ireland, the Law Society

became the first professional body to successfully implement a MOOC with over 2000 participants as part of a formal professional learning program. Since then, MOOCs have demonstrated their potential to attract large numbers of learners, particularly highly qualified professionals to participate in free education programs (Laurillard 2016). Moreover, there are now several accreditation pathways available through MOOCs, and there is a more sophisticated understanding of the issue of completion rates from a learners’ perspective (Henderikx et al. 2017).

MOOCs can be defined as “typically involving structured and sequenced teacher-led activities (e.g. videos, readings, problem-sets) coupled with online assessments and usually some venue for student interactions such as a discussion forum” (Greene et al. 2015, p. 927). This typical and dominant form of a MOOC is usually described as an xMOOC (Downes 2012). In contrast, MOOCs which emphasize connecting with learners through blogs and forums rather than on structured resources are referred to as cMOOCs (McGreal et al. 2013 in Jobe et al. 2014). They are designed so that learners can learn “through practice (construction and responding to feedback), discussion (comments and conversations) and production (negotiating an output for evaluation by others), making it a complex and valuable learning process” (Laurillard 2016, p. 16). The challenge in the tradition of a cMOOC is therefore to design learning experiences that support large numbers of teachers to engage in a model of co-learning, which, as stated by Avalos (2011), involves:

networking and interchanges among schools and situations and is strengthened in formalised experiences such as courses and workshops that introduce peer coaching or support collaboration and joint projects ...the lesson learned is that teachers naturally talk to each other, and that such talk can take on an educational purpose. (cited in Laurillard 2016, p. 3)

Implicit in this statement and arguably the most important requirement is to design and enable opportunities for large numbers of teachers to talk purposefully to one another online. The challenge was how to do this.

Can Deep Learning Conversations Be Recreated Live Online?

Much of the study of interaction in online and distance education contexts has to date focused on asynchronous communication, such as forums (written discussions) (e.g., Blanchette 2011). This body of research has found that asynchronous is valuable for considered discussion, where people have time to reflect and then respond. Except for an Australian study which produced a handbook on the potential of blended synchronous learning (Bower et al. 2014), there is relatively little research conducted on synchronous oral discussions. For example, a recent systematic review of two decades (1995–2014) of research on synchronous online learning found no research articles published before the year 2000, although the work did identify over 150 publications since this date (Martin et al. 2018). Nevertheless, the question if deep discussions can be facilitated using synchronous online learning tools is still an emerging area in the literature. What is known is that, all too often, such live sessions have been found to be overly teacher directed (Hallissy 2014) and lacking in meaningful interaction between the tutor and learners and between learners.

Recent technological advancements can support many activities which have the capability to enhance discussion. These include document sharing, editing, LiveChat, and online polls. Nevertheless, there is still uncertainty if or how these tools can most effectively facilitate deep discussion and if there is a need for additional technologies to enable the “recreation” of the live classroom/learning space online. What is known is that *interaction* is essential to meaningful online learning (Abrami et al. 2011, p. 1246) where interaction is defined by Bannan-Ritland (2002) as a:

two-way communication among two or more people within a learning context, with the purposes either task/instructional completion or social relationship-building, that includes a means for teacher and learner to receive feedback and for adaptation to occur based upon information and activities with which the participants are engaged. (p. 6)

At the same time, there is also the need to be mindful that frequency of interaction does not

equate to quality (Northup 2001 as cited in Hirumi 2002). Not surprisingly, the tutor is key in recreating deep conversations in synchronous online environments. Issues such as the leadership role of the tutor as well as their pedagogical beliefs and disposition must also be taken into account. Laurillard (2002) and Garrison and Cleveland-Innes (2005) place a high value on the leadership role of the tutor in “triggering” discussion and “structuring” to sustain interactions. While the affordances of synchronous online learning tools do matter, knowledge of how to construct and lead discussion using these tools is paramount toward promoting meaningful interaction. The critical factor is that the interaction promoted is a dialogue, i.e., a two-way exchange, where learners are provided with feedback in order to take action (Laurillard 2002). It is through this type of iterative process that learners are believed to deepen their knowledge. Such interactions rely heavily on the skill and competence of the tutor to design quality discussions (Blanchette 2011).

The pedagogical beliefs of the tutor are equally important. Being conversant with the online learning tool technology and comfortable in leading discussion does not ensure that deep discussion will be engaged in by all participants. Rather, Brookfield and Preskill (2005) suggest that if the tutor’s pedagogical beliefs support the design and implementation of social constructivist learning theories, then learners are more likely to engage in deep discussion “live” online; they contend:

Taking discussion seriously moves the centre of power away from the teacher and displaces it in continuously shifting ways among group members. It parallels how we think a democratic system should work in the wider society. In this sense, classroom discussions always have a democratic dimension. (pp. xvii–xviii)

Thus, from this perspective, discussion moves the power away from the tutor toward the creation of a more democratic model of learning where the learners take ownership for their learning. By engaging in this type of discussion, participants stay focused on the topic, offer evidence to support their point of view (or explain the basis for that view), recall and summarize some of the multiple viewpoints that have been shared,

attempt to identify connections between contributions already made, and show how the discussion has changed their thinking or added to their knowledge. In short, they are able to contribute to the creation of new knowledge (Brookfield and Preskill 2005).

In order to design and maintain such critical discussions with their learners, Brookfield and Preskill have identified the following nine dispositions that tutors need to develop (see Table 2). They note that both increasing understanding and resolving conflict are underlying principles of this pedagogy of discussion.

Brookfield and Preskill assert that by developing such dispositions, tutors will be able to engage in intense debate and dialogue. It suggests that the responsibility lies with the tutor to create democratic and challenging environments where they and their learners can engage in deep knowledge construction (Balaji and Chakrabarti 2010). They, as tutor and instructional leader, must inevitably cultivate a presence in such spaces (Stavredes 2011), and their own teaching beliefs and

perspectives will undoubtedly influence this. However, such a role demands high levels of expertise on the part of the tutor who must also be aware of a potential power relationship. It is all too easy for tutors to slip back into using didactic transmission, so they need to be mindful of this. To promote student growth, tutors need to ensure that learners have opportunities to share their views and to engage in discussions. It is also essential that tutors focus on learning to listen and to hear others so that they can use strategies such as questioning, criticism, discussion, and deliberation effectively (Brookfield and Preskill 2005; Bower et al. 2014). In this way, the tutor has a critical role to play in structuring and “scaffolding” the types of interactions that take place online (e.g., Rovai 2004). (The notion of scaffolding is very much associated with the work of Vygotsky (1980) and with a social constructivist view of learning.)

Yet the learner too has a key role to play in such settings as they need to take responsibility for their own learning and engage constructively

MOOCs, Teacher Professional Learning and Deep Learning Conversations, Table 2 Nine discussion dispositions in Brookfield and Preskill (2005)

Disposition	Brief description
<i>Hospitality</i>	The tutor creates an atmosphere where learners feel welcome and secure and one where there is humor
<i>Participation</i>	To maximize participations, tutors must create a democratic classroom where everyone is encouraged to participate and where it is acceptable to remain silent, if so desired. Tutor's role is to manage the discussion and draw students in
<i>Mindfulness</i>	Entails “losing ourselves” by becoming completely absorbed in what somebody else has to say. It involves learning to listen and to hear others and may even involve tutors modeling this behavior for learners
<i>Humility</i>	A willingness to admit that one's knowledge and experience are limited and incomplete and to act accordingly
<i>Mutuality</i>	The notion that our flourishing is contingent on the flourishing of others and this commitment to helping others and working with others leads to trust. It is designed to create a safe place where learners can be open
<i>Deliberation</i>	Refers “to the willingness of participants to discuss issues as fully as possible by offering arguments and counterarguments that are supported by evidence, data, and logic and by holding strongly to these unless there are good reasons to do so” (p. 13). This allows all to engage in robust debate where all views are valued. They note such a disposition takes a long time to create
<i>Appreciation</i>	Bringing people together as few of us take enough opportunities in everyday life to express appreciation to one another for a thoughtful comment, a powerful insight, etc.
<i>Hope</i>	This “provides us with a sense that all of the time, effort, and work will benefit us in the long run, even if only in a small way” (p. 16)
<i>Autonomy</i>	“If democratic classrooms seek to promote individual and collective growth, then people who retain the courage, strength, and resolve to hold on to an opinion not widely shared by others should be given their due” (p. 17)

with the tutor and their peers (Anderson and Garrison 1998). Learners can sometimes become frustrated with discussion viewing it as a waste of their time (Brookfield and Preskill 2005).

While other learners may be considered “lurkers” (Salmon 2000) having “low” or “no visibility” resulting in “silence” online, particularly in synchronous discussions when students are not actively participating, Gulati (2004) notes that:

In some formal online learning discussion, the choice of safety through silence may not be an option. The formality of online practices that aim to promote openness and democratic learning seemed to have ignored the need to feel, free, confident and secure to choose to participate openly or learn silently. (p. 8)

Thus, tutors need to be aware that student silence may be an indication of other feelings such as a lack of confidence or trust to share a view or an opinion. It is at times like this that tutors need to consider how they can create a democratic classroom where everyone is encouraged to participate and where it is acceptable to remain silent. This type of democratic participation is encapsulated in a teacher education context in the Fully Online Learning Community (FOLC) model described by Blayone et al. (2017) that builds on the Community of Inquiry (COI) model, which underpins contemporary approaches to the design of distance education, including MOOCs. This model also underscores the importance of teacher presence coupled with rich and meaningful interactions as the basis of deep learning.

In summary, the literature on synchronous online learning suggests that the role of the tutor in designing and enabling meaningful interactions and discussion is essential. It also suggests that their pedagogical beliefs and their technical knowledge of the online technologies are key to ensuring deep discussions. However, there is limited evidence that synchronous online learning tools, on their own, without skillful facilitation and intervention by tutors can recreate welcome and safe places for learners to engage in open deliberation.

21CLD MOOC: Design and Development

To address the identified gap in the literature regarding synchronous online learning, and the potential of MOOCs as a means of scaling the model of teacher professional learning, funding was secured from Microsoft to design an online course. Working with a partner in the education sector (H2 Learning), the intention was to develop a MOOC that would challenge and enable teachers to examine and change their own classroom practices, as they relate to innovative uses of digital technologies to support their own and their students’ learning and the development of twenty-first-century skills (Fig. 1).

In keeping with Phases 1 and 2 of the teacher professional learning framework, a central feature underpinning the MOOC design was the tenet that it is teachers’ understanding of twenty-first-century skill requirements that influence the ways

MOOCs, Teacher Professional Learning and Deep Learning Conversations, Fig. 1 Phased development of the model of teacher professional learning

in which they use ICT (e.g., Law and Chow 2008). As previously established, when teachers' pedagogical orientations are underpinned by understandings of twenty-first-century learning, they take on a more facilitative role, provide student-centered guidance and feedback, and engage more frequently in exploratory and team-building activities with students. Findings in Phases 1 and 2 (Butler and Leahy 2015) were that change in teachers' pedagogical orientation and the emergence of a culture of self-evaluation was directly attributed to the use of the Learning Activity/Student Work (LASW) framework and the deep discussions they engaged in around their classroom practice. To this end, rooted in the LASW framework (now called 21st century learning design, which has been shortened to be known as 21CLD), an eight-module, self-directed course was designed and developed over a period of 9 months as a core component of the MOOC design. The modules explore what learning looks like in the twenty-first century and how innovative teaching practices can support student learning to develop the key twenty-first-century skills of collaboration, knowledge construction, self-regulation, problem-solving and innovation, skilled communication, and the use of ICT for learning. As well as defining, explaining, and illustrating each of the skills, an integral part of each module is an "in-action" video in which teachers from across the world showcase how they have embedded a specific skill in their classroom. Thirteen teachers from countries such as Finland, Canada, South Africa, and Australia designed these extended learning units for their students which focus on the development of twenty-first-century skills (e.g., collaboration, knowledge construction, etc.) while also embedding the use of a range of digital technologies. The teachers were selected from the global cohort of Microsoft "Teacher Fellows" who understood the LASW framework. The teachers were supported by the design team (lead authors and H2) as they developed and implemented the learning units in their classrooms. Mentoring and feedback was provided individually to the teachers through email and Skype. In addition, regular online meetings were also held with all teachers

and the design team. Over a 3-month period, the teachers captured and documented learning processes and evidence of specific skills using handheld video cameras and uploaded their raw footage to a dedicated online space which was only accessible by the design team. Working with this footage, the design team then constructed a comprehensive "in-action" video for each of the key twenty-first-century skills. This part of the design and development process was the most difficult and time-consuming for the design team as they had to work across a range of time zones, with different school calendars, as well as incomplete and poor-quality video footage to name but a few operational problems. However, the investment in time and resources were crucial as these video resources are key components in the overall design of the 21CLD MOOC. In addition to illustrating a skill in action, these videos are positioned as the focus of the online discussions in which participant teachers analyze and reflect on the learning observed in each classroom.

While the definition, explanation, and illustration of each of the skills, along with the "in-action" videos, formed a core aspect of each module, the team was critically aware of the need to design opportunities for more collaborative and constructivist engagement with teachers to promote "co-learning" (Laurillard 2016). To this end, focused questions related to the design of learning activities were embedded into each MOOC module. However, to promote meaningful co-learning, there was a recognition of the need to challenge and support teachers as they engage in critical discussions around their understandings and classroom experiences of 21CLD in action. Findings from Phases 1 and 2 clearly indicated it is through such discussions that change in teachers' pedagogical orientations is facilitated and, as such, are a key element of the professional learning model. However, these types of discussions are readily supported through face-to-face interactions. The challenge now is to embed such critical discussions in a MOOC environment. This challenge raises many further questions. What type of design is required to promote critically reflective dialogue through asynchronous online

discussion? To what extent will asynchronous discussion fora need to be moderated and supported by other means such as synchronous “live” sessions?

How to Design Opportunities for Deep Learning Conversations Online?

Currently, any teacher can access the MOOC assets developed for the eight modules of the 21CLD course on the Microsoft Educator Platform. Over **33,657 teachers** from **100+ countries** have participated in the 21CLD online program (February 2016–December 2017), conservatively impacting **3,870,640 students per annum**. The 21CLD program consistently remains in the top ten courses on the Microsoft Educator Platform. However, the content has not yet been designed or hosted on a MOOC platform which would lend toward a more blended model of professional learning. Teachers typically interact with the content on an individual basis, and there is limited scope to engage in critical discussion with other teachers.

The next phase of development is therefore to take these assets and to relocate them on an intentionally designed MOOC platform where learner experiences can be constructed to recreate the deep professional learning experiences observed in Phase 1 and Phase 2 of the initiative. To this end, Dublin City University (DCU) has recently joined the FutureLearn platform which in terms of its design was strongly influenced by Laurillard’s conversational framework (Laurillard 2002). However, the challenge remains to design the social supports within the MOOC structure to sustain the collaboration, dialogue, and ongoing reflection that are necessary for the changes in pedagogical orientation and classroom practices. In particular, there is a need to establish if the technology exists to do this and, if so, how to successfully embed it in the teaching and learning experience to support the deep engagement witnessed in Phases 1 and 2.

Cognizant of the experiences in Phases 1 and 2, the design team strove to design a MOOC that could reach large numbers while also providing opportunities for teachers to learn through practice, discussion, and production (Laurillard 2016).

In this sense, there is a requirement for teachers both to try out ideas in their classrooms and report back on their experience so that critical reflection and discussion are promoted, thereby providing opportunities for teachers to share ideas and resources. Incorporating these elements would result in scaling the model of teacher professional learning developed to date that is contextualized and meaningfully rooted in classroom practice. There is a recognition that the creation of a community of practice needs to be built around a MOOC, as opposed to individuals just working through the content on their own.

The challenge for the design the next iteration of the 21CLD MOOC is therefore to explore if it is possible to recreate the collaborative nature of peer coaching and develop the communities of practice that can sustain a culture of self-evaluation. Given that professional learning is most effective when it is grounded in collective discussions of classroom practice (Warren Little 2003), our major concern is how to recreate, in an online environment, those deep learning conversations which are centered on teachers’ classroom practices that were central to teacher learning in Phase 1 and Phase 2. Therefore, in the next iteration of the 21CLD MOOC, the intention is to explore if the synchronous online learning tools are up to the job of facilitating deep deliberation, as defined by Brookfield and Preskill (2005). Thus, the only variable that is being changed from Phase 1 to 2 is the medium through which teachers will engage in deep discussion, moving from face-to-face to online, and this affords an opportunity to explore if and how synchronous online learning tools can support such interaction.

Drawing on the review of literature, there is an awareness of the centrality of the role of the online tutor and the development of certain critical “dispositions” (Brookfield and Preskill 2005) so that participants will be able to engage in intense debate and dialogue. All too often it is too easy for facilitators to slip back into transmission and fill the “air” with their own voices (Laurillard 2002; Brookfield and Preskill 2005). The disposition of *deliberation* appears particularly relevant as it is essential to provide teachers with an opportunity to engage in robust debate around their

MOOCs, Teacher Professional Learning and Deep Learning Conversations, Fig. 2 Possible ways that the 21CLD MOOC can be developed

teaching practices. Deliberation has very much been to the fore in Phases 1 and 2 with teachers engaged in robust discussion embedded in their classroom practices. Other dispositions that would appear to be important would include hospitality and mutuality as there is a responsibility on the facilitator to create an atmosphere of trust where learners feel welcome and secure. They need to design “a safe place where learners can be open that allows learners to share” (Brookfield and Preskill 2005, p. 13). Some learners will be very experienced, while others will be shy, so there is a need to create a sharing environment where they can learn from each other (Laurillard 2002).

The literature also suggests that the facilitators’ pedagogical beliefs and their technical knowledge of the online technologies are key to ensuring deep discussions. To this end for the initial pilot phase of the next iteration, the authors will be the facilitators using synchronous online learning tools to facilitate deep discussion with the 21CLD MOOC assets by working with a group of teachers in the southwest of Ireland recruited by the local teacher education center. However, a basic assumption of this so-called 4th wave is that a one-size model of online professional learning will not fit all and that different strokes will be

needed for different folks depending on the educational context (Picciano 2014). Consequently, in addition to this pilot, a range of other possible MOOC deployment strategies are being considered, as illustrated in Fig. 2.

A blended delivery model may be worthy of further development in an effort to scale up the professional learning model, and to this end an accredited postgraduate certificate and diploma has been developed by the DCU Institute of Education.

Conclusion

In conclusion, this entry has discussed a range of conceptual, theoretical, and practical considerations around the potential of MOOCs for scaling up teacher professional learning. In addition, and in keeping with “the cMOOCs focus on community building, social interaction [and] peer review” (Jobe et al. 2014, p. 1581), the authors want participants to be able to work in peer groups, sharing experiences, ideas, and expertise. This type of MOOC design also aligns with our job-embedded approach that recognizes the value of the experience and expertise that teachers can offer each other (Butler and Leahy 2015).

Although, the 21CLD resources are currently available to a worldwide audience on the Microsoft Educator Platform, the authors have still to develop ways that the school-embedded, job-focused model of teacher professional learning can be scaled effectively so that the teacher professional learning experience is contextualized and rooted in classroom practice. The upcoming piloting of the synchronous online discussions as outline above will begin in Ireland in 2018 by working with the national network of teacher education centers. If this next iteration of the 21CLD MOOC is successful and the deep discussions about learning are recreated successfully online, the logical next step would include the identification of cohorts of teachers at local and regional levels that would be capable of supporting others. In this way, the 21CLD MOOC would be recreating in an online environment the collaborative nature of peer coaching and developing communities of practices that would sustain a culture of self-evaluation similar to that which occurred in Phases 1 and 2.

Introduction

In recent years, many countries in Europe and the rest of the world have invested heavily in digital skills and connectivity, by digitalizing industries, businesses, and public services. These advancements have been made possible by the dynamic development of technology and new innovative services (Luckin et al. 2017). New data-driven technologies and services imply that individuals need to master new skills to effectively integrate the Internet of Things, big data, automation, and artificial intelligence. In the current times, in addition to the acquisition of new skills, there is increased emphasis on some of the innately human skills, such as complex problem-solving, coordinating with others, critical thinking, negotiation, creativity) (WEF 2016). While the automation of industrial, labor-intensive jobs has been an ongoing trend since the 1960s, the new abilities of artificial intelligence (e.g., IBM's Watson and Google's DeepMind) are slowly resulting in a new digital revolution where professionals, such as doctors, nurses, leaders, teachers, and lawyers, who have high levels of expertise, are seeing their role as experts being challenged and transformed (Government 2017). This high pace of change in future workplaces appears to be an increasingly prevalent aspect of our lives. According to the most recent

estimates of World Bank, over the next decade, more than one billion young people will enter the global labor market, and only 40% will be in jobs that currently exist today (Caught 2016). Given the rates of change in modern working contexts, the fundamental requirements of future workers are to be flexible, self-reflective, and adaptive lifetime learners.

In the field of education, new technologies provide stakeholders with new tools and measures processes that can change the core processes of teaching and learning. Training and education are being challenged and changed by the digital transformation, and education is only gradually equipping students with digital skills such as coding and programming. However, these skills alone are not enough as the society moves towards greater automation. Education is responsible for providing today's students the future workforce with skills that are not prone to automation. The focus of education and training should be on skills that make us different from modern technologies, that are fundamentally human and that require human intelligence. These skills include but are not limited to complex problem-solving, social intelligence, emotional intelligence, coordination with other, creativity, and critical thinking.

One approach to providing these new skills is to provide opportunities to learners to work in unison towards solving complex problems in socially interactive, rich learning environments. Some examples of these pedagogical approaches include practice-based learning, problem-based learning, project-based learning, and inquiry-based learning. Contemporary educational researchers and practitioners have endorsed these teaching approaches by explaining their merits in achieving high-tier learning objectives (c.f. Barron and Darling-Hammond 2010). Today, many countries have formally included these skills and pedagogical approaches into their national curricula. However, many scholars have questioned and criticized these pedagogical approaches because their effectiveness in achieving learning outcomes and ensuring content acquisition has not been backed by evidence (Kirschner et al. 2006).

One of the potential reasons for this apparent lack of evidence is that the higher tier learning outcomes that are expected in such pedagogical approaches are extremely difficult to measure, particularly in dynamic learning environments involving group work and open-ended tasks. Therefore, traditional, standardized measurement methods often fail to show the positive impact of such pedagogical approaches on intended learning outcomes. On the other hand, new advances in learning analytics research, particularly multimodal learning analytics (MMLA), offer novel methods that generate distinctive information about what happens when students are engaged in these activities (Worsley and Blikstein 2014).

The focus of this in this entry is on collaborative project-based learning. New advances in learning analytics research, particularly MMLA, offer improved methods that can generate distinctive information about what happens when students are engaged in such collaborative, project-based learning activities. Such information facilitates new understanding of the complexities of collaboration (Blikstein and Worsley 2016; Grover et al. 2016; Martinez-Maldonado et al. 2017; Ochoa et al. 2014). MMLA combines different types of process data (e.g., log data), collected from diverse sensors, log, and trace files. The focus of the analysis is on the timing (temporality) and order (sequence) of activities that learners use during their collaboration. That said, MMLA is an emerging field and, unlike the more traditional learning analytics approaches, it requires adaptation and the building of systems and the use of sensors to collect data from the physical environment, in addition to digital data.

Current research in MMLA focuses on developing a better understanding of the complexity of learning through high-frequency multimodal data capture, signal processing, and machine learning techniques (Ochoa and Worsley 2016). MMLA offers different insights into learning in project-based learning tasks, where students have to create unique artifacts such as computer programs and robots and engage in small-group collaboration to solve open-ended tasks (Blikstein

2013; Blikstein and Worsley 2016). MMLA builds on multimodal human interaction, educational data mining, and many other fields of learning and cognitive sciences to capture the complexity of learning through data-intensive approaches (Siemens and Baker 2012; Worsley 2012).

Structure and Limitations

This short entry presents a brief background on the emerging field of MMLA and argues for its potential to monitor, support, and evaluate students' skill development during constructivist learning activities. The next section briefly describes current MMLA projects in diverse educational settings, with a focus on learners and teachers. This entry concludes with a discussion on the challenges in transferring MMLA from research to practice.

A Brief Background of MMLA

The chapter starts with the premise that across all levels of education, it is common to encounter situations in which learners work in unison to solve problems in socially interactive learning environments. Many experts in education have advocated the use of interactive pedagogical approaches, arguing that they help learners achieve high-tier learning objectives (Barron and Darling-Hammond 2010). However, not much evidence is available on the effectiveness of these methods (Kirschner et al. 2006), and they have been criticized as being ineffective (Kreijns et al. 2003). However, this lack of evidence may also stem from the fact that the higher tier learning outcomes that these pedagogical approaches help achieve are very difficult to measure. Therefore, traditional, standardized measurement methods often fail to show the positive impact of such pedagogical approaches on intended learning outcomes. MMLA offers improved methods that can generate distinctive information about what happens when students are engaged in such constructivist teaching approaches (Worsley 2014). For

instance, students' collaborative problem-solving competences can be interpreted from their non-verbal physical interactions. Such information can enable a new understanding of the complexities of collaboration (Cukurova et al. 2018).

The field of MMLA is rapidly developing across the domains of formal, informal, school, and workplace learning. Different technologies are being used and integrated, and data from sensors, including biometric and computer vision devices (body, limb, finger, face and emotional, object tracking), are being combined with existing learning management systems that span the physical and digital realms. However, most of the MMLA work conducted is still at best a "system prototype" (technology readiness level 3–4) (Commission 2014) or in other words a "highly functional prototype validated in a lab like environment." To verify and validate the work that has been conducted on MMLA, the MMLA community has to identify ways to make MMLA systems easily implementable outside of research and innovation projects. Such efforts can allow for larger scale interventions and grounding in learning theories in line with the aims of learning analytics community.

Specifically, MMLA involves a combination of different types of process data (e.g., log data). The analysis considers the timing (temporality) and order (sequence) of activities that learners use during their engagement with learning activities. The activities involve, for example, overt and visible activities of self-regulated learning (i.e., planning, goal setting, strategic enactment, and reflecting) (Johnson et al. 2011) and invisible mental reactions, such as emotional states measured from physiological signals (Pijera-Díaz et al. 2016). Thus, multimodal learning analytics combines various data sources that reflect the temporal and sequential characteristics of regulated learning over longer periods of time (Cress and Hesse 2013).

Similar results have been obtained in the field of socially shared regulation and collaborative learning (Molenaar 2014) in more traditional and face-to-face learning environments. However, an

advantage of MMLA is that it allows for capturing of detailed information about learner activities, such as which activities learners use and exactly when they use them. Thus, MMLA allows users to jointly consider both cognitive (visible) and emotional (invisible) processes (Nesbit et al. 2007). It can be useful for designing pedagogical approaches (e.g., prompts or scripts) for individuals or groups. For example, "on the fly" process models resulting from learners cognitive and emotional responses inform users about the type of support learners need (Järvelä et al. 2016). Additionally, MMLA makes visible how different types of pedagogical approaches affect the learning process, and finally, it helps evaluate how and when different pedagogical approaches are effective for learning. This potential of MMLA motivates researchers to investigate complex learning processes that occur in constructivist pedagogical settings, with the purpose of observing, evaluating, and eventually supporting these learning processes with MMLA technologies.

Seminal MMLA Projects

An emerging body of work within MMLA research is focused on small-group work and project-based learning. This work is mainly an offshoot of the initial work by Blikstein and Worsley (Blikstein 2013), which investigated engineering students' design activities (Blikstein 2013; Chen et al. 2014; Ochoa et al. 2013). Blikstein (2011) used multimodal techniques to investigate students learning of computer programming by capturing code snapshots and video and gesture tracking for engineering tasks. Worsley (2014) presented different approaches for data classification that showed how multimodal techniques have a significant impact on the relation between research and learning theories. Both of these initial approaches enabled other researchers to begin exploring MMLA with small groups of students across different subjects. Ochoa and colleagues (Ochoa et al. 2013) presented the Math Data and Oral Presentation Quality Data Corpora that has

enabled the MMLA community to analyze and discuss the different requirements and results within this field. Further, Ochoa and colleagues' (Ochoa et al. 2014) used the existing multimedia processing technologies to produce a set of features for accurate predictions of experts among students solving math problems. Their work illustrated the benefits of MMLA in supporting students' learning in these contexts. Similarly, Chen and colleagues (Chen et al. 2014) expanded the Oral Presentation Quality Data corpus to further examine the feasibility of using multimodal technologies for assessing public speaking skills. Grover and colleagues (Grover et al. 2016) explored the development of computational models of social learning environments; they evaluated the quality of collaborations from the body movements and gestures of programmer pairs working together with acceptable accuracy rates. Moving away from most of the existing MMLA research, which focuses on learners' data, Prieto and colleagues (Prieto et al. 2016) and Martinez-Maldonado and colleagues (Martinez-Maldonado et al. 2016) studied how MMLA can support teaching actions and orchestration in the classroom.

To make sense of complex data streams derived from multiple data sources, MMLA researchers employ various computational techniques. These approaches include logistic regressions (Ochoa et al. 2013), different feature reduction algorithms (Schneider and Blikstein 2014; Worsley and Blikstein 2014), and statistical models to identify features and predict student performance. The suitability of these approaches depends on the main research question and the purpose of data analysis. Accordingly, these approaches provide insights into how to proceed with a multimodal dataset. Regardless of which computational approach is taken, the existing literature shows that MMLA can support education in project-based learning approaches, and it has the potential to provide new means of gathering insights for complex, open-ended learning activities (Blikstein and Worsley 2016), which are otherwise extremely challenging to monitor and support through the traditional standardized evaluation approaches.

Current MMLA

Spikol and colleagues (Spikol et al. 2018) investigated nonverbal physical interactions of small groups of students collaborating on open-ended design tasks. The learning analytics system (LAS) captured different features like how the students move, how close they were, and their social engagement. This study showed that MMLA and state-of-the-art computational techniques could use physical interactions of students (Cukurova et al. 2018) to generate insights into the "black box" of student learning in project-based activities. These types of insights, generated from multimodal data, can then be used to inform teachers about the critical features of project-based learning and can help them support students appropriately in similar pedagogical approaches.

Current MMLA studies include research on how to support teachers with wearable technologies like smart glasses that provide real-time perceptions of student performance for orchestrating personalized classrooms (Holstein et al. 2018). Martinez-Maldonado et al. (2018) have focused on the under-explored area of learning analytics in the context of physical/motor learning tasks and the physicality aspects of "traditional" intellectual tasks that often occur in physical learning spaces. They are developing a theoretical framework that uses distributed cognition theory, the Internet of Things, and multimodal learning analytics. Echeverria and colleagues (2018) have employed data storytelling (DS) to improve data visualizations and how MMLA is communicated to learners and educators. They propose a conceptual model that applies DS principles to questions posed in teacher- and students-facing dashboards, which can provide the right type feedback for education.

Discussion

These different MMLA projects and research approaches highlight the need to develop the technology beyond the different system prototypes. The aim should be to create a flexible framework

the offers some options for collecting MMLA data and connecting this data back to standard systems (LMS and LRS) with slow integration and learning analytics specifications (Kitto et al. 2015). Diverse projects have shown promising results for using MMLA to gain insights about understanding and supporting collaborative work (see Martinez-Maldonado et al. 2016; Blikstein and Worsley 2016; Di Mitri et al. 2017; Grover et al. 2016; Prieto et al. 2016). However, in the absence of systems that are easy to use and test, MMLA faces the same challenges as traditional learning analytics in digital learning environments: it is not only difficult to gain traction and acceptance among practitioners but also challenging to overcome the socio-technical problem of using analytics for education, especially to impart twenty-first century skills (Blikstein and Worsley 2016; Di Mitri et al. 2017; Grover et al. 2016; Prieto et al. 2016). As a step forward in this direction, we believe that MMLA research focus more strongly on presenting its real-world impact for practitioners.

The aim is to push MMLA towards data collection and implementation in real-world educational settings that are ecologically valid. Additionally, there is a need to encourage ways to make MMLA readable to humans and machines (Cukurova et al. 2018), which would enable us to validate the technical aspects of theories of learning (Friend Wise and Williamson Schaffer 2015). Closing the gap between research and practice will enable more extensive access to the systems and tools, providing opportunities in real learning settings. Presenting the use and value of MMLA in real-world education settings would contribute positively towards its extensive use and acceptance by practitioners (Cukurova et al. 2018; Spikol et al. 2018).

MMLA research is still an emerging field, and the type and frequency of data pose challenges that are different from the ones associated with conventional learning information (data logs from LMS system). Various initiatives for open learning analytics platforms (Sclater et al. 2015) and related toolkits to handle new types of data sources (Kitto et al. 2015) need to be explored for MMLA. At the same time, new

processes are required to integrate and aggregate data from diverse sensors that can allow researchers to implement, validate, and extend the current research. Some progress has been made to develop new infrastructures to connect new sources of data to LMS that help guide future work (Deakin Crick et al. 2017; Di Mitri et al. 2017; Martinez-Maldonado et al. 2017).

Since MMLA builds on diverse fields of research from education to computer science more exchanges between them are required to solve the various MMLA challenges. Lastly, small group work, where students create unique solutions to open-end and complex problems, offer challenges that may be technical or related to user experience. New ways to support education are required in order for research to contribute to practice. Global educational policies are changing to include computational thinking and twenty-first century digital skills with a strong focus collaborative work to meet the changing digital needs (OECD 2015). To make learners more adaptive, skilled at creativity, and adept at complex problem-solving, along with other skills, new tools and methods are needed, like the different MMLA projects discussed above. MMLA technologies should be used to change how to design, support, and improve learning and training in order to address changes in the global society.

Introduction

The most natural and perhaps richest form of communication is face-to-face communication, but due to the growth of computer systems and Internet usage during the past three decades, new ways of communication have emerged. Computer-mediated communication can be defined as human communication that is maintained or altered through machines. For effective communication, cues other than verbal are important, especially to develop relationships (Walther and Parks 2002). In face-to-face (F2F) communication, emotions are expressed by appearance, facial expression, gesture, and postures, but in CMC social cues are replaced by content, style, and timing of verbal online messages (Walther and Parks 2002). To fill the gap and deal with the lack of nonverbal cues in text-based communication, the interaction has to include some nonverbal cues to express emotion over a period of time.

The term paralinguage was first used by Trager (1958) who defined it in a narrow sense (Pennycook 1985). In 1984 the Education Research Information Center (ERIC) broadened the term to become the “study of those aspects of speech communication that do not pertain to linguistic structure or content, for example, vocal qualifiers, intonation, and body language”

(Houston 1984). This broader definition is consistent with Loveday’s (1982) and used in this entry (Loveday 1982). Emoticons are referred to as “paralinguage of the Internet” (Marvin 1995) and are the graphic representations of facial expressions that many users embed in their electronic text or messages. These symbols are widely known and commonly recognized among computer-mediated communication (CMC).

Carey in his research paper entitled “Paralinguage in CMC” identified five categories of non-verbal cues in CMC: vocal spelling, lexical surrogates, spatial array, manipulation on grammatical markers, and minus feature (Carey 1980). Walther stated that the communication channel must adapt the language to fill the gaps of F2F cues filtered out with some other verbal text-based cues in CMC such as emoticons (“☺”), vocal spelling (“Weeelll, Hummmm”), and grammatical marks (“!!!!, ???”). The nonverbal cues in F2F communication can be replaced by these other paralinguage cues in computer-mediated communication; however, it is important to know how these cues are used. This entry is concerned with presenting and exploring the use of emotion in online and computer-mediated communication.

Computer-Mediated Communication (CMC)

Initially CMC was criticized as not a proper medium for communication for long-term relationship building and that it was more usable for task-oriented communication rather than relationship building (Walther and Parks 2002). However, the theories and literature in regard to CMC have shown that emotional communication and relationship building are possible through CMC. Cues filtered out and cues filtered in theory have suggested that absence of nonverbal cues in F2F is completed by paralinguage cues, chronemics cues (chronemics is the study of time in communication), and some other verbal cues, so in this section, we will review literature regarding how emotion is represented in CMC.

In his paper “Expression of Emotion in Text-Based Communication,” Jeffrey Hancock

conducted a study of how people express and detect emotion during text-based communication (Hancock et al. 2007). The empirical research suggests that most of the cues, which express emotion, are filtered out from CMC (Walther and Parks 2002). Nonetheless, according to Hancock, the display of emotions through text-based communication differs according to their positive and negative emotional state (Hancock et al. 2007). Positive and negative emotions can be uncovered by identifying agreements and disagreements. If too many disagreements occur, it leads to negative emotional chat, and enough agreement leads to positive emotional talk in text-based communications.

Another way to calculate emotion in text-based communication is in identifying different punctuation-like exclamation “!” and question marks “?”. Such punctuation used in communicating makes text-based communication more similar to voice tones and displays emotion through text. The speed of communication is yet another way of calculating emotion, in that if two people are exchanging information through chat too quickly, it is a signal of positive emotion through text-based communication.

Paralanguage Use in CMC

To express emotion further in computer-mediated communication, some paralanguage cues were introduced, and as stated earlier, Carey identified five categories of nonverbal cues in CMC (Carey 1980): vocal spelling, lexical surrogates, spatial array, manipulation on grammatical markers, and the minus feature. Briefly, these are:

1. Vocal spelling: Vocal spelling such as “Weeeelll” is used to express emotions such as frustration, tiredness, and a bored expression. In verbal expression “Weeeelll” shows tiredness of the communicator, but expression meaning changes with context.
2. Lexical surrogates: Lexical surrogates such as “mhmmm” use nonstandard spelling that imitates vocal information or tone.

3. Spatial array: Spatial array is a set of characters; when we read them all together they make some special symbol or meaning, for example, smiley “☺”: it is made of “:”, “-”, and “)”, these all three together display a happy face all together.
4. Manipulated grammatical marks: Manipulated grammatical marks such as (...) indicate pause, (!!!) express puzzled expression, and capitalization of words inform shouts or importance of sentences.
5. Minus features: Minus features refer to an absence of certain language standards that refers to the relaxed mood of the communicator, like a lack of use of capitalization for the starting of a sentence, or writing intentionally a wrong name or words (to show that both sender and receiver are known to each other), or removing of some words from or making them acronyms like “Lots of Laugh” to “Lol” and for your information “FYI”.

These all show a relationship from formal toward personal in CMC; the cues show that there are some which replace vocal nonverbal cues of F2F communication in text-based CMC from theory cues filtered out.

The uses of CMC cues such as nonstandard or multiple punctuation (“...”, “!!!”), lexical surrogate (“hummm, Ohhh, Okay”), stretching of syllables (“Friiiiend”), and capitalization are context sensitive. To know the actual meaning, we need to consider verbal and nonverbal cues equally. On the basis of context, lexical surrogate (“hummm”) means mitigated disagreement, multiple punctuation (“...”) is used to make some pause or discussion, and multiple punctuation (“!!!”) is used to aggravate disagreement, to mock disagreements, or to show exercise of power depending on context and uses. Stretching of syllables and capitalization emulates spoken nonverbal speech. Capitalization can be used to display loudness or pitch. Frequency of use and multiple punctuation is also dependent on production effort for symbols through the keyboard and is mostly observed in equal amounts (Vandergriff 2013).

Online Teaching, Emotions, and Emoticons in Computer-Mediated Communication, Table 1 Types of emoticons and paralanguage cues and their uses according

to literature research (Carey 1980; Chen and Liu 2006; Rezabek and Cochenour 1998; Vandergriff 2013; Walther and D’Addario 2001)

Name of cues	Graphical representation of cue	Intended meaning	Emotional side (positive/negative/mixed)
Smiley	☺ :-)	Happy, solidarity, support	Positive
Sad	☹ :-)	Sadness, negative, feeling, despair, confusion	Negative
Wink	;-)	Humor, teasing, sarcasm	Mixed
Teasing	:p	Teasing, sarcasm	Mixed
Intensify laugh	:-D	Huge happiness, sometimes sarcasm	Positive
Multiple full stops	. . .	To give praise in conversation or to give time to think, concern	Mixed
Multiple elimination	!!!	To show excitability or high affects, sometimes also display confusion	Mixed
Lexical surrogate	Hmmm	Convey skepticism or disagreements sometime	Negative
Capitalization of words	PLEASE DISCUSS	Convey loudness or stress, emphases	Mixed
Extending spelling	Friiieeennddss	Sometimes use as F2F nonverbal cues for giving stress on point by focusing on it	Mixed

Emoticons and their Use in CMC

Emoticons are graphic representations of facial expressions that many users embed in their electronic text or messages and are referred as “paralanguage of the Internet” (Marvin 1995). In regard to the display of facial emotions, similar to that in F2F communication, computer-mediated communication replaces those cues with emoticons. The emoticon is constructed of two words “emotion” and “icon,” and the main purpose of emoticons is to convey nonlinguistic information that face-to-face communication depicts with facial expressions, as depicted in Table 1. Emoticons are highly used cues in CMC for displaying emotion through ASCII keywords, which resemble the face in text-based communication. A definition from pioneer researchers in the field of CMC for emoticons is as follows: “An ASCII graphics used to indicate emotional state” (Walther and D’Addario 2001). Emoticons are also known as visual and graphical cues formed with ordinary keyboard typographical symbols that when read with text written before and after that symbol represent emotions of senders (Rezabek and Cochenour 1998).

Smiley faces ☺ were introduced by a computer scientist at Carnegie Mellon University, Scott Fahlman. When changing the position of the “)” character to “(”, it becomes a “frowny” face “☹”. Smiley has evolved from ASCII characters to graphics, and nowadays many action cartoons are being used by CMC channels (Dresner and Herring 2010). In the research paper “Function of the nonverbal cues in CMC,” the researcher explained that use of the smiley has a cultural touch also in CMC (Dresner and Herring 2010) and explained that use of CMC emoticons varies according to culture; for example, in Japanese conversation they use “Kaomoji” (^-^) which resembles a happy Japanese face.

Walther and D’Addario studied potential effects of emoticons for expression of emotion of two types – affective positive and affective negative – which showed that it is true that the effect of emoticons is strong in overall interpretation of messages (Walther and D’Addario 2001). According to the study, there are two types of uses of emoticons, where one is used to strengthen a message and the other use makes the message ambiguous, as it contains mixed

feelings with nongeneric use of emoticons. In their research paper “The Impacts of emoticons in message interpretation,” Walther said that the intensity of a message mostly comes in only verbal text as is written. He said that nonverbal cues such as smiley and paralanguage cues sometimes tone up the meaning or interpretation of the message. Walther and D’Addario in 2001 worked on the analysis of positive effects of emoticons in positive texts sent by a sender. They also related information regarding mixed uses of emoticons in CMC. For example, they studied when a normal message or negative message is sent by a sender with positive emoticon or when a positive or normal message is sent with negative emoticons. This conveys mixed feelings in the sentence and thus to the receiver. Such uses of emoticons are ambiguous, and according to Walther, it is hard to understand the true feeling of a sender in such messages (Walther and D’Addario 2001).

Winks as emoticons are very ambiguous to interpret, just as the meaning of some emoticons can be ambiguous. It is constructed with a half smiley “:-)” and half part of winks “p”. Winks suggest other dimensions of feeling such as sarcasm or humor. These kinds of emoticons give a message a sarcastic tone (Rezabek and Cochenour 1998; Walther and D’Addario 2001).

An Online CMC Project and Emoticons

The behavior of displaying emotion through emoticons, punctuations, lexical surrogate, capitalization, and other cues varies in the context of CMC settings and depends very much on whether it is monitored, non-monitored, one-to-one, or group communication. It also confirms individuals’ perceptions of social presence in the visible and non-visible chat conditions. As reviewed in the literature, the degree of social presence is more affected by visibility than monitoring ability since the delivery of nonverbal cues through visual channels plays a critical role in perceiving social presence (Daejoong et al. 2013).

A study based on a qualitative content analysis of students’ text-based synchronous online communication from an inter-institutional online course on computer-mediated communication and remote collaboration was conducted, and data collected over a 5-year period support these findings (Connolly et al. 2017). The project was part of software engineering-related courses at 3 institutions in Europe, with a diverse ethnic grouping and age band; on average, approximately 60 students attended the course with one-third of the students female and two-thirds male. The undergraduate and postgraduate students had several online meetings during each week of the project duration and all team communication recorded. The students were aware and understood that all communication would be analyzed for research purposes and to determine their contribution to the remote collaboration, i.e., the chat logs were also relevant for the grades they received as part of their course of study.

The research question aimed to discover how different emoticons and other paralanguage cues were used in CMC in terms of frequency of use within the student population. The chat logs were analyzed and had the following characteristics:

- Available data was purely text-based.
- Data generated by mixed working groups (mixed in terms of nationality and gender).
- Chat logs showed a variety of characteristics in terms of communication; for example, it had instances of introductory communication, team building, decision-making, emotion and disagreement in communication.
- Chat logs had a wide variety of paralanguage used by communicators.

The research findings, regarding the use of emoticons and paralanguage cues, demonstrated the reliance on emotion in communication by the students, through both positive and negative reinforcement of the message (Connolly et al. 2017). The findings showed how emoticons (“:-)”), nonstandard/multiple punctuation (“...”, “!!!”),

lexical surrogates (“hummm, Ohhh, Okkay”), stretching of syllables (“Friiiiend”), and capitalization are used in a computer-mediated communication remote collaboration project and the frequency of use of emoticons and other cues. The students, at times, used emoticons and paralinguistic cues in support of the verbal sentence, and there was also evidence of the use of such features, contrary to the meaning of the sentence. Lastly, the use of emoticons and paralinguistic cues could be ambiguous and affect the message, signified by the overuse and overreliance on emoticons or paralinguistic cues in conveying their message.

Such results establish at least three different kinds of use visible in CMC for emoticons and paralinguistic cues. Most popular and common use was to strengthen a message by using emoticons, which supported verbal messages, and in such cases, the interpretation of emoticons was straightforward. The second use was in mixed messages, when use of emoticons and paralinguistic cues did not match the verbal messages’ meanings and where interpretation of emoticons used was ambiguous. The third use, visible in CMC, occurred when there was an overuse of emoticons and paralinguistic cues. There is also evidence that there were emoticons and paralinguistic cues used in sentences, where it did not add any emotion to the sentence, and these were visible often.

Conclusions

Emoticons play a significant role in clarifying message intention, compensating for the absence of nonverbal cues, and there is clearly a prevalence and frequency of use among university-attending students. Notwithstanding these observations communication is rapidly evolving through the use of electronic means, and the findings show the reliance on paralinguistic and emoticons in our electronic communication to compensate for one of the most important cues in human communication, facial expression. Paralinguistic cues and emoticons contribute to a social presence in an electronic

world and enrich the text-based communication channels.

Introduction

The whole world is now striving toward achieving universal access to high-quality education which is the key to the achievement of peace and sustainable social and economic development. In a bid to help learners in utilizing high-quality educational content and materials, open educational resources (OER) present free accessibility to essential content as well as opportunities for reusability and sharing (Willems and Bossu 2012). Open educational resources are free learning resources accessible and available on the Internet. OER can be defined as “materials used to support education that may be freely accessed, reused, modified and shared by anyone (Downes, 2011). In a related vein, OER are teaching, learning and research resources that resides in the public domain or have been released under an intellectual property license that permits their free use and re-purposing by others. OER include full course, course materials, modules, textbooks, streaming videos, tests, software, and any other tools, materials, or techniques used to support access to knowledge” (The William and Flora Hewlett Foundation n.d.).

As pointed out by Commonwealth of Learning (2013), OER can be openly licensed or can be put in the public domain, to use or reuse freely. They

can exist in many formats such as text print or electronic, audio, video, multimedia, or hypermedia, or in combinations of all. OER can also be based on a single learning including a lesson, a series of lessons (a module), whole course, or even an entire program of study. OER can support a specific methodology or approach, be it constructivist and or behaviorist or combination of both. There may be differences in format, structure, or approach, but they still share a common characteristic that is openness.

OER are actually open implying that with open license, the person who create retain ownership of their work and can specify how open they want their resources to be, i.e., from fully open to closed for a particular purpose. Compared to commercial resources, OER can be used and reused as needed and desired by learners and teachers. Similarly, they can (Commonwealth of Learning 2013) be edited to reflect the styles and approaches of the users, can be managed by the insertion of new materials as it becomes known or available, and can be customized, repurposed, or adapted to reflect the others of your organization.

As open educational resources are useful in the regular learning, so also it is to the distance learning. Online learning started as a type of distance education technology in the 1980s and 1990s. Other distance education technologies were paper-based correspondence courses and later video- or satellite-based along with some other technologies. What differentiates online learning is that transmission occurs through the Internet-connected computers, while in the distance education, students and faculty do not need to be in the same place at the same time.

The role of distance education is changing drastically both at micro and macro context. Education has no longer remained the prerogative of institutions, or even knowledge has no longer remained under the sole control of teachers only. Through OER, an effective platform has been created not only in strengthening the open and distance education in the developing nations where there has been real shortage of creating knowledge pool for developing useful courseware but also empowering them to build their capacity to participate effectively in producing the open

courseware. However, much have been done in the area of OER. Researchers have looked at the issue holistically in terms of conceptualization, benefits, opportunities, and challenges within the context of regular learning mode; however, discussion on OER as it relates to distance learning particularly in the developing countries has not been so much researched and discussed. It is on this note that this entry looks at OER in terms of concept analysis, evolutionary background, impacts and relevance to the distance learning, challenges, and the way forward.

Concept of Open Education Resources

Open educational resources can be described as “technology-enabled, open provision of educational resources for consultation, use and adaptation by a community of users for non-commercial purposes.” They are usually made freely available over the Web or the Internet. They comprise of learning objects such as lecture material, references and readings, simulations, experiments and demonstrations, as well as syllabi, curricula, and teachers’ guides (UNESCO 2002).

The concept includes free (that is no cost is charged) and open (for update and modification) resources such as digital content, open-source software courses; course-related materials such as syllabi, lecturers, lesson plans, and assignments; textbooks; or collections of digital media including libraries of images and videos (Geith and Vignare 2017). The truth about OER is founded on the academic traditions of freely and openly sharing and extending knowledge (OECD 2007). In this manner, OER extend the concept of the public commons, as well as the ideas of open-source software into education (Udas 2007).

Open educational resources are teaching, learning, or research materials that are available to the public or released with an intellectual property license that gives room for free use, adaptation, and distribution (UNESCO 2009). They are available freely for everyone to use or reuse, whether a person is an instructor, student, or self-learner. Prominent among them are full programs, program modules, curriculum materials

from teaching sessions in different formats, assessment resources, assignments from quizzes to exam papers to e-assessment, lab classroom activities, teaching materials, games and simulations, and many more resources, contained in digital media collections around the world (JISC 2013).

OER can be regarded as a subset of broader term which is open education. As put forward by the William and Flora Hewlett Foundation (n.d.), open education is the simple and powerful idea that the world’s knowledge is a public good and that technology in general and the World Wide Web in particular provide a distinctive opportunity for all to share, use, and reuse the knowledge. In furtherance to this, open educational resources are digitized materials provided freely and openly for educators, students, and self-learners to use and reuse for teaching, learning, and research. For further clarification, open educational resources encapsulate:

- Implementation resources: Intellectual property licenses to promote open publishing of materials, design principles of best practice, and localize content
- Learning content: Full courses, courseware, content modules, learning objects, collections, and journals
- Tools: Software to support the development, use, reuse, and delivery of learning content, including searching and organization of content, content and learning management systems, content development tools, and online learning communities

Arising from the series of definitions, it can be deduced that “OER” are both large and indefinite. A great diversity of objects and online materials can be categorized as educational resources, from courses and course components, to museum collections, to open-access journals and reference works. Over the years, the term has come to cover not only content but also learning and content management software and content development tools and standards and licensing tools for publishing digital resources, which allow users to adapt resources in accordance with their cultural,

curricular, and pedagogical requirements. The following section features the different types and elements of OER beginning with an illustrative figure.

Why OER in Distance Learning?

OER, open educational resources, are supported by educators who believe that sharing is important for learning. They wanted to use affordable (free) learning resources; have the legal rights to use these (free) learning resources; have updated content; translate resources into other languages; broaden access to learning; and ensure publicly funded educational resources are available to the public (Commonwealth of Learning 2013).

As agreed generally, the main purpose of the OER is to create an opportunity for open-access to high-quality digitized educational materials for building capacity at all levels. Due to eruption and ignition of knowledge and advancement of information and communication technology (ICT), there has been huge and colossal requirement for one to update herself/himself, and as a result more number of participating institutions/agencies are joining this digitized club with the basic philosophy of openness. It could therefore be observed that the basic rationale for the need of OER basically is due to the following (Jena 2010):

Capacity building: OER endeavor is made possible not only as an opportunity in building the capacity of the individual but also of the institutions through effective networking. For instance, the teachers have to search for materials having capacity to be useful resources based on the most updated knowledge, which further enables them to adapt and reuse and thereby remarkably assists them to build their own capacity, and also they can further contribute for modifying the resource materials by providing essential feedback out of their own experiences.

Access and distribution of learning resources: OER assist in ushering collegiality and online collaboration among the educators who not only share development of learning resources but also help increase the quality of learning resources that are available beyond the four walls of the

classrooms. Since the learning materials are available at the public domain for use, which otherwise would have remained inaccessible.

Best practices: OER are majorly stored in databases or repositories. Since process of documenting the resources is undertaken scientifically, hence there is ample scope to store the best practices in the form of source form, which are usually unseen. This helps both educators and the organization to show the practices in their local situation with suitable adaption.

Collaborative efforts: The idea behind OER basically enhances in cooperating efforts in creating learning resources, more specifically in the context of developing countries. As the whole effort of collaboration is online, the materials can be infinitely customized, and the availability of appropriate free content license is also ensured. Thus, this enables the professionals to lead developments and contribute immensely to the knowledge community as active partner. These collaborative efforts facilitate in material development process and help in empowering educators to demonstrate their potentialities.

Research: OER have strong component of research. Any resource material gets developed under the free content principles and in a collaborative manner requires having strong basis of research. Since its primary goal is to create and host free content, multimedia learning materials, resources, and curricula for all age groups irrespective of languages, a scientific method of approaching the material development process becomes a component of basic research. In the same vein, the efficient use of these materials and feedback generated helps to further enhance the quality of resource materials.

Evolutionary Background of Open Educational Resources

The development of OER in higher education in the twenty-first century is part of the much larger social movement toward opening up what was formerly closed to all except a limited number of people who paid for access to use information and services. In the late 1990s and early 2000s, a

number of OER initiatives were launched at universities with support from public agencies and private foundations; chief among these is the William and Flora Hewlett Foundation. These attempts generated openly available course syllabi, textbooks, math education materials, and platforms for user-generated content. Recognizing the challenge of locating and vetting OER content, the National Science Foundation also funded development of curated pathways to open instructional content on the Web. In these years, countless domain-specific online resources have been created and deposited either with major platforms or on university and college websites and repositories. OER admirers' communities have collaborated with major gatherings such as the OpenED Annual Conference. Later, OER proponents introduced services to buttress successful OER integration by universities and colleges.

As D'Antoni (2009: 3) points out, the OER movements are a young movement with just a decade of development. It had its beginning in 1999 through grassroots project such as Richard Baranuik's initiative at Rice University that eventually became the Connexions project (Baranuik 2008) and through large-scale institutional initiatives, such as MIT's OpenCourseWare (OCW) project (Carson 2009) which inspired others such as Johns Hopkins Bloomberg School of Public Health. Other institutions such as the Open University (OU) in the UK and Open University of the Netherlands (OUNL) also joined the OER through somewhat unexpectedly as, unlike a traditional campus-based institution such as MIT, their core business is distance education.

International efforts have also played a major role. In the UK, substantial investments from the Higher Education Funding Council and the Joint Information Systems Committee funded a program to support both open content creation and technical infrastructure (Allen and Seaman 2014). In the year 2005, the OCW Consortium was launched to provide an international forum and community, and in 2007, an international convening conference aiming at promoting OER resulted in the Cape Town Open Education Declaration which was signed and embraced by many enthusiasts (Bakia et al. 2015).

Relevance and Impacts of OER on Distance Learning/Education

Many effective and efficient OER platforms have been created to strengthen the open and distance education in the developing nations, where there has been shortage of knowledge creation for developing useful courseware, and also empower them to build their capacity to participate effectively in producing the open courseware. It has potentials to facilitate the open and distance education system in the following ways (Jena 2010):

Professional growth: In most of the developing nations, the ODL institutions are basically targeted for meeting the educational needs of the disadvantaged groups. OER facilitate in enhancing personal knowledge of both distance teachers and learners through effective planning and active support of ICT. It also helps the distance teachers to undertake systemic researches in a more scientific and objective manner and quickly share the same across the professionals.

Repository of learning content: Free learning contents get developed in the form of full courses, courseware/course materials, and content modules, learning objects, collection, and journals with the joint support of online communities having common interest. The physical distance between the experts has been almost reduced in the process of sharing the ideas and process of developing the courseware. The collective responsibility calls for standardizing the courseware in a more scientific way suitable in the various contexts.

E-learning initiatives: A strong network is being created for successful planning, designing, development, and implementation of materials necessarily to be used for effective e-learning, which most of the distance education institutions have been contemplating around the world. This calls for building the capacity of professionals via such open materials which could be shared, used, and reused in the context. Similarly all components of e-learning could also be facilitated, be it learning through online, assessment procedures, admission, other administrative issues, etc., through the support of open courseware. The

open and distance learning (ODL) institutions have strong potentiality of sharing the software to support the creation, delivery, use, and improvement of open learning content.

Licensing under Creative Commons: There has been always a feeling that the open and distance learning (ODL) system undergoes tremendous pressure on the intellectual property licenses to promote open publishing of materials, production of best practices, and localization of content. Since the production of OER goes beyond the scope of the institutions that primarily take initiatives in creating the materials, multiple partners join in the process with the objective to further strengthen the content. Further the materials are created and licensed under a “Creative Commons” used freely online, and hence it no longer remains the property of one individual and organization. “Creative Commons and other open licenses allow materials the potential to be readily reused in an OpenCourseWare or other educational product” (Caswell et al. 2008: 12). Since materials are freely available and their use and adaptation are encouraged under the Creative Commons license, the ODL system can be strengthened particularly in the context of developing nations.

Forum for professionals: With the support of online communities, the ODL system gets facilitated to establish the forums of professional discussion not only within the boundary of one nation but also beyond. The initiative of COL through its project WikiEducator is worth mentioning to bridge the digital divide in the context of empowering underdeveloped and developing nations. The whole initiative also extends maximum benefits to such small Commonwealth nations through its project Virtual Universities for Small States of the Commonwealth (VUSSC), which otherwise would have never been benefited due to their dispersed sociocultural reasons. As the ODL institutions are brought to the network, the professionals of these institutions collaborate virtually on national and international initiatives, which is more cost-effective. The cost on course development process and its delivery remains almost negligible as the materials are accessed anywhere at any point of time.

Consortium for course development: As has been observed, a growing momentum is taking place among the distance learning institutions to participate in the course development process by forming consortium for OpenCourseWare development. Many of the distance learning institutions have committed to launch an opencourseware Website with the primary objective to share their courses. The open courseware (OCW) consortium is established online to assist the OCW movement worldwide. The member institutions are linked with the consortium site real time. In fact the participating institutions can upload their syllabi of the course, lecture notes, assignments, and examination requirements through the consortium site. Through this OER initiative, each ODL institution will have potentiality to create its “learning object repository” for the effective use of its learner and thereby will meet its social obligations.

There are a number of perceived impacts and limitations in the use of OER in distance education (Lane 2010; Hatzipanagos 2012, 2013). They are seen to be displaced from proprietary “silos,” i.e., the institutional virtual learning environments, hence breaking the authorization barriers that these impose and they also copyright “free,” as contributions to collective knowledge. However, they most often come against recent improvements in creation of technology-enhanced learning content, as they can be didactic in nature, the reason being that interaction is frequently nonexistent or poorly scripted in OER learning design. They are also often compact shells to fit within context and meaning. Context and wraparound activities are missing as interactive aspects and their learning design are separated from content and are both implicit rather than explicit (ibid.).

According to the Commonwealth of Learning (2015), the benefits of open education include the following: open to anyone; ideally affordable and free; students can try the course before signing up; flexible study times not bound by weekly timetables or semester calendars; students work at their own pace; available from anywhere and not restricted by access to school or college; access

to huge amount of study materials; and intellectual capital is available for reuse.

Commonwealth of Learning (2013) explained further that OER are a significant component of making open education possible. As has been seen from the preceding definitions, OER are free; are digital (also non-digital), accessible through the Internet and not bound geographically; adaptable, allowing others to repurpose them for new uses; support learning at one's own pace; and allow access to huge amounts of data and information through OER repositories.

OER are believed to provide economies of scale as the same resource that can be reused in a variety of different teaching contexts and provide instances of good practice to help academics improve their teaching (Conole and Brown 2018). Baranuik (2008) lists the principles underpinning the open education movement including knowledge should be free and open to use and reuse, collaboration should be easier, individuals should receive kudos and credit for contributing to education and research, and that concepts and ideas should be linked in unusual and surprising ways and not in the simple linear forms presented in today's textbooks.

There was an ingenious assumption that simply making OER available in repositories would mean that they would be used by teachers and learners; however, evaluation of early OER initiatives such as the Open University UK's OpenLearn repository showed that this was not the case as the take-up by teachers and learners was low (Lane and McAndrew 2010). There is now an understanding of the barriers to using OER (De Hart et al. 2015).

Commonwealth of Learning (2015) also added that there are many benefits associated with the use of OER in addition to sharing which is an important component of any educational experience. With OER, the author retains ownership of his or her copyright without having to assign it to a publisher, thereby protecting and preserving the author's rights. Moreover, open licenses require that attribution be given to the author when an OER is reused, revised, remixed, or redistributed. Plagiarism problem is less when a work can be freely copied. There is no incentive to lie about the

source or to deny attribution. OER are also an excellent way of marketing an institution and spreading its name internationally.

Challenges of OER in Distance Learning and the Way Forward

Within the realm of open and distance learning, the potentiality of OER is restricted to sharing the resources purely for the academic pursuits. If OER are specifically designed to support a courseware, through the Creative Commons and by using electronic resources, it is also essential to find out the means on how to make it largely available in the local context where technology is not supportive and effective particularly in the developing nations.

The developing nations need to be supported extensively when it comes to the issue of making available the free software tool that can enable any individual to download the materials, adapt them to meet the localized needs, and contribute to the field of knowledge through the consortium of creative commons under copyright and licensing. There is also the need to develop extraordinary feedback apparatus or system to study the efficacy and usability of the materials which is supposed to assist dispersed targets with diversified needs through online learning environment.

The OER movement is linked vertically and horizontally within terms of creating awareness and developing effective network of professionals. This is essentially needed by way of ensuring quality materials are kept for use and to address the issue of sustainability which is inbuilt to a new approach for flexible learning and sharing of knowledge in the open distance learning (ODL) context.

It should also be noted that most of the OER initiatives in our institutions are undertaken on a project basis and supported by external funding bodies. For the movement to be very strong, prosper, thrive, and sustained, the whole initiative needs to be institutionalized particularly in the context of ODL system.

Aside from the aforementioned challenges, others which can be discussed are technical

constraints such as lack of interoperability and unavailability of technical specifications as indicated by (Tuomi 2005). This is assumed and can limit openness. Similarly, the learning resources can be used but are usually passworded in learning management systems and not available to external users.

There is also social constraints issue. This is sometimes institutional or economic. For instance, copyright can limit access to resources. Ethical standard associated with research and study can as well limit access. Mentioned can be made of privacy reasons. Social constraints are complex systems with conflicting tensions, where money can buy more access and political power can be used to change institutional constraints.

Hatzipanagos and Jon Gregson (2015) investigated the constraints and barriers in using OER. A key constraint according to the respondents of the survey was a limited understanding of their value. They also alluded to a cultural resistance whose facets were a “new thing,” “not developed here,” “can we trust it?,” etc. However, the main, often repeated perceived barrier in discussions was a lack of staff development to familiarize academics with the nature and opportunities of OER and time to search and explore repositories of OER for suitable learning and teaching resources. This is similar to the investigations by UKOER/SCORE 2014, where lack of digital literacies does feature highly as a barrier to OER, although follow-up interviews that were carried out suggested that finding/evaluating quality OER is a time issue not a skill issue, and likewise many staff avoid releasing OER due to the time involved in making them sufficiently polished and fully compliant to legal issue.

Another prominent challenge associated with the use of OER is the issue of finance. Finance undermines the potential to build the capacity of developing world education systems because it focuses on the spending of money to produce OER in the developed world. As long as financial resources of this kind are expended predominantly in the developed world, there is likely to be little progress in developing the capacity of

developing world education systems to meet the needs of their learners.

Another important challenge that undermines the transformative potential of OER has been an increasingly heated debate around commercialization of “free content.”

This debate most often finds practical expression in arguments about Creative Commons licensing framework and whether or not it is a welcome idea to impose what is described as a “noncommercial” restriction within the license. The reason that this argument has emerged is that, to many people, the concept of creating a noncommercial restriction seems intuitive in order to prevent unfair exploitation of “free” content. However, as many have argued passionately, it has turned out that such a restriction can have several unintended results in the long term, preventing the “mixing” of content with different license conditions and creating unforeseen complexities. These critics go on to observe that the share-alike licensing condition in the Creative Commons licensing framework serves effectively the same purpose as a noncommercial restriction by requiring derivative works to be released under similar licensing limitation by requiring derivative work to be released under similar licensing condition as the real content on which the derivation was anchored. They are also of the opinion that closing down the possibilities for commercial exploitation of derived works may result in long-term problems in sustainability of the emerging educational commons. It is evident that many of these proponents are pushed by a well-desired motive to see content made free, mirroring similar debates that have surrounded open-source software. There is a necessary cause to some extent, but frequently results to logical leaps of faith that are not yet sustained by meaningful evidence that can be educational challenging.

The most noticeable is the belief that making content free to copy, adapt, and exploit commercially in and of itself will lead to better education delivery, particularly in the developing nation. Relating to this is the assertion that free content is the same as educational content. It is evidently possible that free content will make a contribution to improving education; however, this assumption

needs to be proven through demonstration and good practice, not claimed as a fact without evidence. Those who subscribe to educational potentials and quality of OER as a fact without providing supporting evidence erode or subvert the weight of their own argument among skeptics of the OER movement. Numerous concepts such as open learning, distance education, and e-learning have less popularity in terms of potentials because they have been associated with wild claims about the educational impact they would have that have not been borne out in practice. The supporters of the concept of OERs associated removal of unnecessary licensing restrictions that might govern them could be usefully seen to prove this potential through demonstration and good practice not rhetoric. Essentially, it is censorious and analytical to recognize that making content free is only one aspect of which may require to ensure that the quality of education is systematically configured and improved. This apparent fact is frequently lost in the arguments that have emerged, thereby drifting attention away from the critical broader argument about education configuration that can be catalyzed through discussions on OER. Associated with this concern is the point that, even, several proponents of the argument against non-commercial restrictions that the emerging opinionatedness or assertiveness being exhibited by opponents of non-commercial restrictions serves only to oppress those who are taking the first temporal actions towards freeing up restrictive license governing their educational content. The school of thought holds that a spectrum of license is necessary to give people and organizations the choice in deciding the best way to start contributing to the growing pool of available OER. This seems to make sense practically. If a person or institution is designing a course and can distribute to learners a specific journal article free of cost, but is not allowed to modify its text, this seems preferable than not being able to use it at all. Similarly, there may be forceful or irresistible cases for making sure that in some instances, content that is made available for use should not be open for modification, for instance, journal

Open Educational Resources and Distance Learning, Challenges and the Way Forward in Higher Education, Fig. 1 Types of open educational resources. (Source: ALA Annual Conference 2016)

articles or treaties which report specific research findings or encapsulates a special perspective.

The Way Forward

It should be noteworthy that to be successful and sustainable, development of OER in distance learning cannot be unrecognized or ignored within a university. It must be unified into institutional processes in order for both to grip its potential and provide for its sustainability. Likewise, institutional policies, particularly around intellectual property rights, remuneration, and promotion, need to be modified and habituated to support intellectual property rights, remuneration, and promotion and need to be adapted to support and sustain development and use of OER for distance learning, to methodically and invariably improve and update curricula and teaching materials, lessen operating costs, develop institutional capacity, and manage growing distance learning students group successfully.

The promise or capability of OER in distance learning involves bringing lucidity and transparency to educational procedures, enabling cooperation between faculty members and students at

different institutions, and initiating a new economic stereotype or idea for securing, preparing, issuing, or publishing learning materials. Fundamentally, crucial and indispensable to the success of OER in distance learning will be to demonstrate that in the short to long term, it will assist highly occupied faculty members to control their work more successfully, instead of combining additional work requirements to their job responsibilities. However, effective OER ideas or movements will be the one that function immediately and add educational value with the available information communication infrastructure challenges of any participating institutions inclusive of those from developing nations. Demonstrating the quality of a concept that will only have effects when the infrastructural limitations are eliminated is of little merit to higher education institutions in their little to middling term.

Pedagogical Possibilities for the History of Computing

Christopher Leslie
South China University of Technology,
Guangzhou, People's Republic of China

[Classroom](#); [Historiography](#); [Innovation](#); [Syllabus](#); [Teaching](#)

The history of computing is a strikingly interdisciplinary field. It is not only that it joins two fields. What is more, the two disciplinary components, history and computing, are diverse in themselves. In addition, work in the history of technology is also conducted in an interdisciplinary manner, such as under the aegis of gender studies or science and technology studies. This provides many pedagogical opportunities for approaching history of computing in the classroom. An overview of these approaches can be garnered from professional associations and online syllabus repositories (SIGCIS 2018). Although this seems to result in a bias toward US courses in English, it does

seem as if until recently this topic was most often covered in a US context.

This article begins with a review of courses offered in the history of computing. The trajectory of the field and the STS lessons points the way to future directions. Following this, overview is a list of pedagogical best practices. The field known as science and technology studies (STS) offers suggestions to avoid pitfalls of developing classes of this type.

Overview of History of Computing Courses

It is not surprising that histories of computing in the classroom vary depending on the goal of the program offering the course. Accreditation standards also play a role. A brief overview of the progression of history of computing classes demonstrates how they have changed to meet the needs of various constituents.

Evolution Not Revolution

The earliest courses in computing often had at least a portion of the curriculum devoted to the history of computation tools. This history had various purposes. One was a way of attracting more people to the field by showing how important computation was to society. Another was to suggest that computers were really not as novel as they might seem. In an effort to create the impression that computers were calculating tools like

any other, these courses covered in broad strokes the history of computation to show that they were not mysterious. This effort took place in the context of the first computer science programs, which were housed in departments of mathematics or sciences and served an agenda of legitimizing the study of computation as a separate concern.

For instance, in 1958 at Concord High School in Massachusetts, educators offered an advanced mathematics course for high school seniors. The course included information about the history of computing tools and number systems in general, as well as providing awareness of current and future progress in computing. The course impressed upon students the idea that the main change brought about by computers was that they were more flexible than the earlier tools that were used. The course included instruction on using slide rules as well as a demonstration of how to calculate a rocket's trajectory with a computer at MIT's Lincoln Laboratory.

One of the first courses in the history of computing at the university level was taught in 1975 at the University of Kansas, Lawrence by Walter Sedelow, a sociologist who had worked at System Development Corporation (SDC, a company founded to work on the SAGE missile defense system, an early computing project) and the United States' Advanced Research Projects Agency (ARPA, a US government agency that was an early promoter of computing and created ARPAnet). The professor used his experience at SDC and ARPA to lecture about contemporary topics, including J. C. R. Licklider and computing at ARPA.

Another example of early offerings in the 1980s was by historian William Aspray, who was at Harvard for 1 year in his early career. He offered a first-year seminar and later a full course from a business perspective called "The US Computer Industry." In addition, Brian Stuart offered a course on the history of computing hardware at Rhodes College. In this class, students wrote and ran code for a restored PDP-8 and for an ENIAC emulator. Thomas J. Bergin began teaching a history of computing course at American University in 1988. As he describes it, students in other

programs had insightful courses about the history of the profession they sought to enter, and he believed the same would be helpful for computer science students. Bergin would go on to coauthor a book on the history of programming languages in 1996. These snapshots show that there was a variety of approaches to incorporating history into computing from the very beginning.

Accreditation standards helped the history of computing gain an academic foothold. ACM's Curriculum 78, for instance, recognized that social and ethical issues in addition to technical challenges should be considered by professionals when making computer applications. This stance was reiterated by the Computer Science Accreditation Board in 1984. The requirement could be fulfilled, according to accreditors, with a standalone, upper-level undergraduate course along the theme of computers and society. This course, according to the guidelines, could have a history component. This would encourage a curriculum that asked for social science models to understand how computers impact society, legal issues, and the public perception of computing. Because it was a separate course, it could be taught by faculty with a humanities or social science background, leading to an institutional pull for supporting this kind of work at universities that had accredited computer science departments. Later, the ACM/IEEE Computer Society published its Computing Curriculum 2001 standards which mandated historical coverage in several courses as well as exposure to social and professional issues and their historical context. This encouraged computer science programs to reach out to colleagues in other fields, either for advice or instructional support.

History of computing entered the university at a time when the history of science and technology was undergoing something of a sea change. An often-cited article, "Should the History of Science Be Rated X?" (Brush 1974), noted that science and engineering were not the isolated, objective pursuits they purported to be. This new thinking about science and technology meant that it could be subjected to historical analysis. Historians started to notice that scientists operate

subjectively, and so historians must do more than document solutions to scientific or technical problems. An historian “must be prepared to analyze the philosophical, psychological, and sociological aspects of scientific work, to explain how . . . particular standards happened to be accepted for evaluating solutions,” Brush wrote. This insight was particularly important in the history of computing and history of technology more broadly, where a multitude of solutions could be proposed to any particular human challenge. The choice of one particular solution based on its perceived fit with ideological, economic, or political goals is not an objective statement about the solution’s value but a subjective choice like any other choice an historical subject faces.

Thomas Kuhn (1962) had already proposed that there was more than objective fact behind the development of scientific theories. In *Structure of Scientific Revolutions*, he pointed out that there were many complications to the notion that the Earth was not the center of the universe, and so scientists had to account for the development of scientific ideas “in terms other than those of linear progress from error toward truth.” This nonlinear development would become even more relevant to technological devices like computers. It was in this context that the AFIPS started the academic journal *Annals of the History of Computing* in 1979. The original editorial board was made up of scholars who had expertise in computer science and included, at least in its earlier years, commentary and memoirs from those who had witnessed momentous events.

There were several textbooks used for these early courses, and the list shows the diversity of the approaches taken by the instructors. The primary texts were historical overviews like *The Computer from Pascal to von Neumann* (Goldstine 1973); the author was a collaborator of John von Neumann, the polymath who was a pivotal figure in the early days of programmable computing. Another widely used text was *A History of Computing Technology* (Williams 1985); the author was the instructor of a course at the University of Calgary. *The U.S. Computer Industry* (Brock 1975) was also frequently used.

Professionalization

In the 1990s, some courses relevant to this survey appeared in history or interdisciplinary departments, such as at the Illinois Institute of Technology, Stanford University, and the University of Manchester. Some of the current themes of history of computing courses are seen then, including women and computing. A majority of the courses were offered by computer science departments because they had a primary audience of computer science students who needed technical expertise at that same time they were expected to understand the historical, ethical, and other issues by accreditors. Some of these courses also had the aim of helping computer science students develop professional skills like writing. These courses appeared at Virginia Tech, the University of Calgary, Purdue, Swansea University, Georgia Tech, Eastern Michigan University, the University of Warwick, American University, and Princeton, among others.

The courses in the 1990s continued to be varied in their approach. Some, like courses at Virginia Tech taught by John A. N. Lee and at Swansea University taught by John Tucker, were general professionalization seminars that included information about the history of the field to convey the trajectory of their profession to students who were on their way to becoming practitioners. These asked students to conduct research reports to hone their communication skills. Convincing women to return to computing was a concern on the 1990s, and so courses like Jon Agar’s course at Manchester University included female figures in their curricula to help recruiting.

Other courses were part of the general education, offered wholly or in part outside of a computer science department. One was a joint project at MIT between the departments of computer science, electrical engineering, and science and technology studies. Spearheaded by David Mindell, this course sought to help students understand engineering practice better. Through case studies from history about a technology, company, or individual, students were introduced to vital issues like teamwork, oral presentations, and critical thinking. In 1994, Paul Edwards taught a

history of computing course at Stanford that was cross-listed as an introductory computer science course. This course sought to demonstrate the complex interactions between innovation and society in their historical context. Similarly, Michael S. Mahoney, a professor of history who had earlier expressed interest in the history of mathematics, offered a first-year seminar at Princeton in 1997 called *The World of the Computer*.

Some professors added articles from the *Annals* to their courses, along with new textbooks that had become available. Those interested in the use of primary sources could refer to a book like *Charles Babbage: On the Principles and Development of the Calculator and Other Seminal Writings* (Morrison et al. 1961). Computers and society were covered by books like the anthology *Social Issues in Computing* (Gotlieb and Borodin 1973) and *Hackers: Heroes of the Computer Revolution* (Levy 1984). A book about the prehistory of computers was *Reckoners: The Prehistory of the Digital Computer* (Ceruzzi 1983). Business history was offered by *Fire in the Valley: The Making of the Personal Computer* (Freiberger and Swaine 1984). Books about hardware were *Alan Turing: The Enigma* (Hodges 1983) and *Bit by Bit: An Illustrated History of Computers* (Augarten 1984). Various combinations of these texts appeared as required reading on syllabi in the 1990s.

For many years, John A. N. Lee at Virginia Tech was a proponent of including history, ethics, and other humanities or social science material in the computer science curriculum (Aker and Aspray 2004). This led him to create a large repository of Web pages that could be used for teaching such courses or for offering online versions of them. Lee, who had been chair of the International Federation of Information Processing (IFIP) Technical Committee 9 for the Social Impact of the Computer, used the opportunity to explore how making material available on the Web could impact teaching on history and other subjects. By 1997, his resources totaled over 3,000 pages. Due to the many courses required for the computer science degree, one

approach Lee advocated was that a part of the so-called humanities requirement offered outside the computer science department be tuned to the history of computing. Lee, along with Williams, John Impagliazzo, and Martin Campbell-Kelly, collaborated on a report published in the *Annals* (Impagliazzo et al. 1999) to encourage such a history course explicitly designed for computer science students.

Turn Toward Informatics

Toward the start of the new millennium, there was an increasing interest in studying applications of computers in other fields, often under the rubric of informatics. Although computer science had largely won its battle to become a separate discipline, this had been accomplished by applying tools of mathematical and scientific rigor to research. Not all uses of computing, it became clear, involved scientific research even though they were demanding in their own ways. Informatics, a new form of academic discipline that considered computation and society more generally, began to appear.

The trend toward informatics resulted in various outcomes. A 1999 course at Rensselaer Polytechnic Institute by Kim Fortun is illustrative because it started with the ideas of the book as an information tool. The course “IT Revolution – Myth or Reality?” sought to demonstrate how IT is innovated and how a student can become an innovator. The course required students to interview an IT researcher, and it included professional goals like requiring students to use gender-neutral language. At Indiana University in Bloomington in 2000, Mehmet M. Dalkilic offered one of the first courses in informatics, demonstrating how technology and people work together and how information works in business. His goal in covering the history of how information is stored and calculated was to think about constraints.

Another offering of this type was about the history of software. In 2003, Michael Mahoney at Princeton offered a new course “The World of Software,” partly based on his interest in system software but also reaching into bioinformatics, gaming, hypertext, and other applications outside

of computer science. Christopher Kelty offered a special topics course at Harvard University in 2007.

The expansion in the variety of computer history classes was aided by ABET's Curriculum 2001, which required that undergraduate students spend a total of 16 h on social and professional issues. This requirement included history, but it also suggested other topics that were amenable to historical approaches, such as ethics, privacy, civil liberties, and so on. In many cases, this led to the development of specialized courses taught by professionals in the humanities and social sciences, whereas before these topics could more easily be incorporated into computing courses.

A new generation of history books supported this turn toward informatics. Perhaps preeminent among them were *Computer: A History of the Information Machine* (Campbell-Kelly and Aspray 1996) and *The Virtual Community* (Rheingold 1993). Other books also appeared on syllabuses at this time, like *Crystal Fire: The Birth of the Information Age* (Riordan and Hoddeson 1997) and an anthology, *A Nation Transformed by Information* (Chandler and Cortada 2000).

It was in this context that new books suitable for college courses and research about software also emerged. *From Airline Reservations to Sonic the Hedgehog: A History of the Software Industry* (Campbell-Kelly 2003) is probably the best known. There were also books for the popular press like *Go To: The Story of the Math Majors, Bridge Players, Engineers, Chess Wizards, Maverick Scientists and Iconoclasts – The Programmers Who Created the Software Revolution* (Lohr 2001) and the proceedings anthology *History of Computing: Software Issues* (Hashagen et al. 2002).

Several academic books with a broader scope were also offered by MIT Press, such as Ceruzzi (1998) *A History of Modern Computing*. In this text, Ceruzzi focuses primarily on the development of hardware in the US context. Janet Abbate (2000) *Inventing the Internet* focuses on networking, starting from experiments in packet-switched networks in the 1960s through the development of the WorldWideWeb application in the 1990s.

Abbate also focuses on a primarily US context. Milton Mueller (2002) *Ruling the Root: Internet Governance and the Taming of Cyberspace* combines policy and economics with computer history to understand innovation better.

In the 1990s, computer science departments saw a renewed attention to recruiting students and faculty from traditionally underrepresented groups, particularly women, to the profession. Accordingly, at the start of the new millennium, new work was published for use in college classes to understand the interactions between gender and technology. Representative texts are *Unlocking the Clubhouse: Women in Computing* (Margolis and Fisher 2002) and *When Computers Were Human* (Grier 2005). These books were typically assigned to support a portion of a course that was related to diversity.

Computers and Society

Perhaps bolstered by the broader definition of computing offered by informatics, the start of the twenty-first century saw a widening of the types of courses that provided insight into the history of computing. It is not as if the types of courses outlined above were discontinued, however. To the contrary, there continued to be introductory computer science courses that included a history component, history of computing courses that sought to introduce professionalization, and so forth. In addition, there was greater attention from a variety of disciplines that used the history of computing in a new context. At the start of the twenty-first century, a place in computing for more everyday individuals had been secured, and professors from many disciplines turned their attention to the field as they would any other growing phenomenon.

As before when considering a new development, professors sought an historical context. Accordingly, an examination of historical narratives are found in a variety of computing and society courses in various disciplines, even those not expressly devoted to history. At the University of Namur in Belgium, for instance, a 2002 course by Marie d'Udekem-Gevers was given on the theme of anthropological approaches to information,

“Approche anthropologique de l’informatique.” In 2004 at Brown University, Roger B. Blumberg offered a first-year seminar that put computing ethics into an historical context, thinking about utilitarianism and republican ideals as well as the history of the concept of human nature.

Courses were also offered to connect the history of computing to a larger social context. Abbate offered a course on internet and governance in 2008 as an STS course at Virginia Tech. Bernard Geoghegan offered a course on computers and globalization at the American University of Paris that same year. Courses inflected by business history were also popular. Michael Mahoney, in 2007 at Princeton, taught a history of computing course that was heavily influenced by business history. At the University of Pennsylvania in 2009, Nathan Ensmenger expressly reached out to humanities and social science students and crafted a history of computing course that used computing technology as evidence of wider human activities, like management and labor. These courses depended upon the discipline of computing history to varying extents, but they sought to expand the audience for the field.

These interdisciplinary voyages into the history of computing were inspired by and also supportive of new studies. For instance, a popular management-side study *Where Wizards Stay Up Late: The Origins of the Internet* (Hafner and Lyon 1996) offered a journalistic account of the managers who brought together ARPAnet that is still referenced 20 years later. *The Social Life of Information* (Brown and Duguid 2000) came from a business perspective to show how companies add value to information and, instead being threatened by a new paradigm, would show the way to the future. *The Dream Machine: J.C.R. Licklider and the Revolution that Made Computing Personal* (Waldrop 2001) similarly came from a management perspective to show how the dream of interconnected research centers evolved into the personal computer. Manuel Castells (2001) *The Internet Galaxy* offered to managers a philosophy of the Internet and mused on how it would change culture and business. These texts often appear in the syllabi of courses in the early 2000s.

From a social history standpoint, *What the Dormouse Said: How the Sixties Counterculture Shaped the Personal Computer* (Markoff 2005) offered a different type of history, suggesting it was counterculture, and not business culture, that produced the personal computer. This theme is also explored in *Bootstrapping: Douglas Englebart, Coevolution, and the Origins of Personal Computing* (Bardini 2000) and *From Counterculture to Cyberculture: Stewart Brand, the Whole Earth Network, and the Rise of Digital Utopianism* (Turner 2006). As a counterpoint to the institutional histories, these books were used in college courses when instructors want to remind their students that the ideals of collaboration and counterculture were important forces in the development of computing.

Books from a variety of other disciplines also start to be seen in syllabi at this time. Legal studies was represented by *Code and Other Laws of Cyberspace* (Lessig 1999), which shows how important concepts like the commons are behind the transformative power of computing. An influential media studies book often seen on syllabi was *Remediation: Understanding New Media* (Bolter and Grusin 1999), a book that takes an historical look at the transformation of content when it is transferred from an old to a new medium. These texts were used in courses when professors sought to show how what seemed to be new in computing actually had historical precedent.

Several books from the perspective of literary studies also began to appear in discipline-specific contexts. *How We Became Posthuman: Virtual Bodies in Cybernetics, Literature, and Informatics* (Hayles 1999) put contemporary fiction and philosophy into its historical context to suggest that we have always been posthuman. A poetic reflection on Vannevar Bush and the origins of personal computing, *Othermindedness: The Emergence of Network Culture* (Joyce 2000) considers how computing is shaped by a historical imagination of information. Lev Manovich (2001), in *Language of New Media*, grounds his analysis of the forms of computing in their historical roots in media. Courses in the humanities that used to these books sought to ground computing in the disciplines in its historical context.

Limitations of Master Narratives

The profession of history in general has been distrustful of metanarratives since at least the 1960s, and the idea of one universal history for all people at all times has been long derided by historians of many types. Although US professors dominated the earliest forays into the history of computing and, lacking a tradition, it seemed necessary for them to first craft a standard history of computing from the perspective most relevant to students in U.S. universities, there was no reason that telling the history from other perspectives was impossible. This change came about when professors outside the USA began to consider national histories. A series of four workshops from 2003–2014 sponsored by the International Federation of Information Processing's Working Group 9.7 on the history of computing, for instance, focused on Nordic computing and its workshop in 2006 focused on Soviet and Russian computing. These demonstrated the potential of this opportunity. Classes in the past 10 years have started to show revisions and resistance to one standardized history of computing.

A book translated from the French, *The Universal History of Computing: From the Abacus to the Quantum Computer* (Ifrah 2002), began to appear in courses at this time. In spite of the word “universal” in its title; the book seeks to demonstrate the global and historical context for computing, showing that contemporary developments in computing are dependent upon a worldwide collaboration over many years to make automated calculation possible. *Networking Peripheries: Technological Futures and the Myth of Digital Universalism* (Chan 2014) makes this point more directly. *Cybernetic Revolutionaries: Technology and Politics in Allende's Chile* (Medina 2014) is used in courses because it shows how histories from outside the core institutions in the United States provide valuable insights into computing. *The Undersea Network (Sign, Storage, Transmission)* (Starosielski 2015) shows how communication networks before the Internet had much to say about the current development of global telecommunication; innovations do not remake the landscape anew.

Recent courses that reflect this interconnection between computing and the history of the globalized world are represented by Rebecca Slayton's 2010 course at Stanford, “Imagining the Computer, Wiring the World,” which uses some of the standardized history of computing but also covers the cultures that gave rise to transformations in computer history and their global consequences. In 2016, Paul N. Edwards offered “Computers and the Internet: A Global History” that intertwines international histories with the standard core history of development in the United States.

One problem with the standardized history of computing is that it reflects the notion that it was largely independent, male geniuses and only male-dominated institutions that were relevant to the history of computing. In Fall 2016, Marie Hicks turned the history around, telling it from the perspective of women in her course “Women in Computing History” at the Illinois Institute of Technology. In the same semester, Joy Lisi Rankin offered “Histories of Computing and Gender” at Lyman Briggs College. New books to complement earlier studies on syllabuses in this context are Abbate (2012) *Recoding Gender: Women's Changing Participation in Computing* and Hicks's (2017) own *Programmed Inequality: How Britain Discarded Women Technologists and Lost Its Edge in Computing*.

It is also clear that the standard history of computing focuses on new devices without considering the sourcing of the material used to build them or their environmental impact, such as the heat produced by server farms. This lack of attention has proven to be another opportunity for professors. In 2015 at the Victoria University of Wellington, for instance, a course entitled “Sustainability and Information Systems” was offered by Janet Toland. This course engages information management students in sustainable practices for information management, considering to some extent the historical case and the need for policy change.

Future Directions

It is no longer a question whether computer science is a viable field, given the large number of

computer science departments, and so it is no longer as imperative as it once was for courses to provide a history of computation in order to assert the importance or to make computing familiar. Nevertheless, professors continue to innovate how computing can be considered in its historical context. New directions are likely to follow innovations in the use of computing and architectures of computing hardware.

As increasing attention is given to new topics in computer science, one would expect for there a similar variety of courses to be offered as was seen for the history of computing more generally. As suggested by this overview, the first attention to history of a new topic will be given within computer science courses themselves to provide a familiar starting point for students. Then, in the computer science departments, courses about history (that sometimes falls in line with concerns of ethics or professionalization) will be offered, and then specialized courses offered by humanities professionals (either in computer science department or in humanities departments), as well as outsiders in a variety of humanities or social science fields, will be developed.

This is seen in recent courses in artificial intelligence, which require students to think in new ways about programming. Current textbooks offer a brief overview of these topics in the same way that general computing courses once did. A recent book, *Prehistory of the Cloud* by Tung-Hui Hu (2016), points out that the seemingly new phenomenon of cloud computing is built on an existing telecommunication infrastructure. New developments can be covered academically in fairly predictable ways. In support of her university's new interest in gaming, for instance, Laine Nooney offered a course, "Video Games: Culture and Industry," that put computer gaming into its historical and analog contexts at New York University in 2014.

As artificial intelligence, gaming, hardware security, cloud computing, and the Internet of Things become increasingly important areas for the innovation and use of computing, new pathways through the history become apparent. In the same way that early computer history courses showed the many ways in which the forerunners

to computation were essential to society, future courses in the history of computers will be needed both to demystify new devices, recruit students to emerging fields, and help the general population understand them. Courses about the history of security to support cyber- and hardware security, the social and legal history of privacy to help evaluate computer privacy, the development of schema for modeling intelligence to enhance the innovation of artificial intelligence, and the history of the built environment for context of the Internet of Things will play important roles in college courses to come.

The trend for localized histories of computing will also be of increasing importance in the future. As many countries come to terms with computerization and the consequences of technology, it will be important for college classrooms to craft national histories that recast the standard history into local terms. These histories will, in turn, help to revise the standard history in a way that better reflects the international scope of computing.

Potential Pitfalls

There are several potential pitfalls with respect to history of computing curricula that might not be obvious to someone who is a member of one of the component groups of this interdisciplinary field. Two of them are a reliance on so-called whig history, and the other is technological determinism.

Whig History

One common complaint from science and technology studies practitioners are histories that employ what is known as a "whig" perspective. This is a term borrowed from British politics. One can imagine a member of the conservative Whig party telling a story of how the present state of affairs came about inevitably, leaving no alternatives. In the history of technology, a whig history suggests that the present moment has come about from an inviolable series of technological advances.

An historical approach based on a whig history is one where there were not branching paths or

alternatives in the development of technology. In other words, technological progress is cumulative without sidetracks or multiple possibilities. When telling a whig history of technology, it seems as if the merits of an idea alone determine whether it will be successful and that the best idea always is successful. Apparently, there were never any errors, misunderstandings, or challenges to good ideas. In a whig history, advantages that come from alliances with existing economic, political, ideological, or legal institutions are ignored. What happened had to happen in the way it happened, and there were no alternatives that could have come into being had they gained greater credence.

This appellation came in the 1930s from outside the history of technology by Herbert Butterfield to decry English constitutional historians, in telling of the forward-looking liberals struggling with conservatives. History in this sense is presented as a progressive force, with all developments leading up to the present moment and projecting a path into the future. In the 1970s, the term came to be used by historians of science as a caution against those who would suggest that the past reflects present concerns, with the result that anyone who does not accept the supposedly inevitable path toward modern ideas is not using the correct analysis. Historian Donald Cardwell (2003) took up this problem in his essay "Reflections on Some Problems in the History of Science," where he notes that each age thinks about science differently, and as well, each age has a different idea of what history itself is. Thus, it is impossible to think of "autonomous histories" of science, reading backward into earlier discoveries to prove that each was a stepping stone to the present. While the doctrine of progress is compelling, he goes on, it is not the case that everyone who did not work toward the present understanding is a fool.

Historians should be able to account for more than one path, Caldwell says, but also should not believe that all matters of importance have already begun to be solved and it is the task of the future simply to "tidy up the ends." Endowing science with a progressive force of historical inevitability, Caldwell says, shuts off the critical mind. In education, this will inhibit innovation because it is not

as if great ideas were "handed down by some celestial text-book writer to whom there were immediately self-evident." Whig versions of history are helpful when the pedagogical goal is to make problem solvers who work within accepted paradigms. For innovators, a history of the contingent is necessary.

Sociologist Bruno Latour is often invoked to combat the simplistic thinking behind whig history. In *Pasteurization of France* (Latour 1988), for instance, Latour notes how competing methods of public health were defeated when Pasteur found an alliance with the clean streets model of public health. In other words, it was not the veracity of his invention that caused it to be adopted, but in fact his ability to make an analogy to a popular movement even though it did not support his science. In the realm of technology, Latour writes *Aramis* (1996), a "scientifiction" of a public transportation system in France that failed to be constructed. In his personification of Aramis, Latour describes how a plausible system that passed its feasibility tests failed to gain a foothold in the imagination of politicians and the public in order to be built. These texts show how actor-network theory offers an alternative to the smooth, steady progress of technology.

Technological Determinism

Technological determinism must be avoided when teaching the history of technology. A technological deterministic analysis suggests that culture is inevitably transformed by using a technology, and this is often used to prescribe a policy proposal. For instance, one might suggest that using computers must inevitably make people more democratic, and so distributing low-cost computers will inevitably increase free thinking.

Using the development of the television as an example, Raymond Williams (1974) has pointed out that determinism is a fallacy because visions about what a device can do precede the technical capability to make it happen. Visions of using television were quite different than what was actually the use in practice. What is more, he points out, the same device was used in different ways in liberal and authoritarian countries: as a

consumer good for families in the former and as a tool for neighborhood viewing in the latter. Although a device must exist, to some degree, in harmony with the ideology that surrounds it, it does not determine changes to the culture independent of history, economics, law, and so on.

Sally Wyatt (2007) has suggested the intellectual habit of naming historical periods for their dominant technological devices is a form of reductionist thinking dependent on technological determinism. She reminds us that technological devices are not invented outside the societies in which they are used, and that devices cannot unilaterally transform them. This obviates human choice, she says, and more importantly it absolves humans from their abuses. She suggests that this attitude is helpful for the purveyors of new technologies because workers and consumers are then seen as powerless to criticize the use and consequences of technological choice.

One way to refrain from determinism is to recognize that technologies are socially constructed. Science and technology studies scholars, like Bijker et al. (1987), have offered the example of the invention of the bicycle to explain how this process is different from determinism. It is impossible, they write, to look back in time and find a moment when the bicycle was invented because there were many contemporary designs for what a bicycle could be. A determinist interpretation would seek to find the essential characteristics of the present design in the past, but a constructivist asks a different question: how were the various designs seen as separate from each other, and why was it that a particular set of design choices come to be known as the obvious and natural default design for a bicycle? In understanding how a competing set of acceptable alternatives were winnowed away into one naturalized design, one can see how social groups and other imperatives play a role in technical development. It is not as if one design was best, or that one design was demanded by one unified market. Instead, the solution that was successful was the one that fit in best with the overall social and economic system.

Policy Rationales and Integration Rationales, Implications for Subject Area Teaching

Sarah Howard

Faculty of Social Science, University of Wollongong, Wollongong, NSW, Australia

Over the past three decades, the number of national educational policies addressing technology integration in teaching and learning has significantly increased. Rationales for these policies have largely reflected the perception that the world is more technological and to raise the quality of national workforces schools must prepare students to compete in a knowledge economy (Kozma 2008). The problem is that these national aims do not translate to technology integration in teaching and learning (Hammond 2014). As a result, high-level educational technology policies often will have limited impact on teachers' practice and student learning.

One of the key reasons for this problem is a lack of alignment between national educational technology policy and curriculum. The recontextualization of educational policy to the classroom is largely a political rather than educational practice, which is often driven by a social agenda rather than teaching and learning. As such, rationales for technology education policy are often oversimplified, which often makes them unattainable in practice. As such, policy often treats digital technology integration as a homogenous practice, which does not address the specifics of learning and teaching in subject and learning areas (Howard et al. 2015a). "Teachers accept or resist particular reforms according to . . . their academic subject orientations and commitments, and their school's identity" (Hargreaves and Goodson 2006). However, policies are unlikely to address the processes of technology integration and teacher change or make explicit connections to teaching and learning (Levin 2008). Schools and teachers will often feel unclear about how they should engage with expectations of educational policy, while ensuring that students are

meeting learning expectations and subject curriculum outcomes. Therefore, a disconnect between policy and classroom integration is often present, which affects the overall impact of educational technology policy.

This article will address educational technology policy rationalizations and how they are recontextualized within educational systems and aligned with teaching and learning. Further, it will discuss how educational policy enables and constrains technology integration in teaching and learning and problematizes teaching in specific subject and learning areas. Progress in this area will be discussed.

Educational Technology Policy

Internationally, it is relatively agreed that use of digital technologies promotes social, economic, and educational change and innovation. The importance of information and communication technologies (ICTs) in peoples' daily lives, in business operations, and in education is accepted internationally. The Organization for Economic Cooperation and Development's (OECD) Programme for the International Assessment of Adult Competencies (PIAAC) (OECD 2017b) and the Programme for International Student Assessment (PISA) (OECD 2017a) both include repeated measures for adult and students' numeracy, literacy, and problem-solving in technology rich environments. The PISA studies in 2003 and 2012 explicitly addressed students' capacity to use digital technologies, stating that ICTs "have revolutionized virtually every aspect of our life and work" (OECD 2015). Results from these tests are used in both developed and developing nations to guide educational technology policy.

The current OECD outlook for future work is that automation and computer intelligence will play a large role, and those not prepared for such changes will suffer limited prospects (Elliott 2017). Helsper and Reisdorf (2016) and other researchers in the area of digital inclusion have long stressed the association between the effective use of technology and future inclusion and

participation in society. Those that are not able to harness digital technologies will not flourish in future society. Recommendations such as this guide national social, economic, and educational policy development. They provide countries with strong rationales for national educational technology investment and initiatives.

National Policies

The World Bank (2017a) has stated that “with globalization, the information revolution, and increasing demands for a highly skilled workforce, nations are increasingly prioritizing education” (para 1). However, decision making about how to do this is often inconsistent. Government agendas shape educational policy, but agendas are influenced by social and political pressures (Connelly et al. 2007). Using publications such as these from the OECD, individual nations can decide how they will prepare young people for this future, through creation of relevant educational technology national policy. For example, consistent social pressure to motivate the creation of national ICT education policies, such as Singapore’s ICT Masterplan (Singapore Educational Technology Division 2015c) and Australia’s past Digital Education Revolution (Department of Education Employment and Workplace Relations 2012), are required. Both of these policies are driven by the rationale that young people need to be prepared to compete in current and future global societies, but they address the issue in different ways. In Singapore, the policy was first implemented in 1997 “to enrich and transform the learning environments of our students and equip them with the critical competencies and dispositions to succeed in a knowledge economy” (Singapore Educational Technology Division 2015d). In 2015, this focus was specifically to promote “teachers as designers” and “school leaders as culture builders” (Singapore Educational Technology Division 2015e). In Australia, the policy was more about infrastructure; providing computers and broadband connections to schools, the logic being that having a personal device would promote students to have the types of competencies needed to be competitive in future work and learning. Both of these policy initiatives are based on the idea of developing twenty-first

century competencies, which were strongly supported by the OECD (e.g., OECD/CERI 2008). These represent some of the complexities addressing educational technology, where two very different approaches to technology integration come from the same rationale.

To help policy makers navigate ICT in education, The World Bank created the *Systems Approach for Better Education Results* (SABER; The World Bank 2017b). This tool provides support for policy makers in “assessing and benchmarking their own ICT-in-education policies against those of comparable countries around the world” (The World Bank 2017b; para 1). One of the key reasons for using benchmarking as a way to address educational technology policy, as outlined by The World Bank, is that there is little accessible data showing impact of ICTs in education. While there is clear consensus about *how* digital technologies are used in work, there is a lack of evidence about the benefits of using and *why* digital technologies should be used in teaching and learning. This has complicated development and implementation of educational technology policy and is part of the reason why there is a disconnect between the policy and integration in the classroom.

Policy Rationales

The development of national educational policy can be divided into two approaches: strategic and operational (Kozma 2008). Strategic policies will often act as a tool to motivate and stimulate change to address a nation’s overall educational goals. National educational goals are often based on high-level needs of society, such as an improved work force for the future and producing better educated citizens. Common rationales for strategic educational technology policies have been preparing citizens for “future work” in the United Kingdom (e.g., Department for Digital Culture Media & Sport 2017), increasing participation in a knowledge-based economy (e.g., EU Science Hub 2017), creating democratic access to learning for all individuals (U.S. Department of Education 2017b), just to identify a few. Strategic policies provide a future vision and direction for ICT initiatives and justification for funding

necessary to make it all happen (Kozma 2008). Therefore, they are by nature high-level broad goals and have tended to be oversimplified (Hammond 2014).

The second type of educational policy, operational, are where strategic policy visions are realized. They will often have a more pragmatic focus, such as setting up programs and resources to support change in relation to national educational goals. In many cases, this type of policy will be tied to a strategic policy. Therefore, it is likely to have a more direct connection to implementation at the state, district, or school level. An example of this is the national “Funding Digital Learning” (FDL) program in the United States, which is linked to the strategic National Educational Technology Plan (NETP; U.S. Department of Education 2017a). The strategic NETP vision of technology in education is one of “equity, active use, and collaborative leadership to make everywhere, all-the-time learning possible” (para 1). Good connectivity and infrastructure are key aspects, as outlined in the NETP, to make “all-the-time learning” possible. The FDL program is designed as an operational approach to provide funds to purchase digital or related resources for states and districts to fulfil NETP aims. The rationale for the FDL program is to support technology upgrades, to keep pace with technological change, and improve instruction and student outcomes. The FDL represents a particular approach to help district and state leadership realize that aspect of the national plan.

Considering Singapore’s ICT Masterplan again, the realization of this policy illustrates the connection between strategic and operational policies. The Masterplan is now in its fourth version (Singapore Educational Technology Division 2015c). As stated earlier, it is a strategic policy based on the rationale that it is necessary to put “quality learning in the hands of every learner – empowered with technology” (Singapore Educational Technology Division 2015e). This policy is operationalized through four “approaches”: (1) deeper ICT integration; (2) sustained professional learning; (3) translational research, innovation, and scaling; and (4) connected ICT learning

ecosystem (Singapore Educational Technology Division 2015a). Each of these approaches have a number of individual priority areas, which are addressed through specific programs or initiatives. A specific element of this is the operationalized policy Cyber Wellness, which is part of “Deepening Digital Learning” in Approach 1. The rationale for this is the importance of internet users having positive well-being and that it is a necessary aspect of appropriate technology use in teaching and learning (Singapore Educational Technology Division 2015b). This has been realized in part of the Singapore ICT Connection website for teachers and students to access.

These examples demonstrate how broadly defined educational technology policy is implemented within an educational system. The process of translating and operationalizing a strategic policy requires recontextualization. This means that policies are interpreted to suit values, needs, and requirements of a given context. The process of recontextualization changes the intent and goals each time the policy is translated to a new part of an educational system. Depending on the context and the nature of the policy as it is operationalized, it may result in good (meaning matching values, needs, and requirements) alignment between the policy and the context or not. If not, the policy is likely to lack impact.

Policy Alignment

The assessment of alignment is one of the ways policies can be analyzed to determine its impact, but also a way to identify where policies need reconsideration. Policies can be evaluated for horizontal, vertical, and strategic-operational alignment (Kozma 2008). “Horizontal” alignment relates to compatibility of policy goals and other policies in a system, such as curriculum and teacher training. “Vertical” alignment is the coordination of policy between different levels of an educational system, such as agreement between the state, district, or school levels. Alignment in these two areas ensures that resources are appropriately allocated across a district and in schools, but also that policies are working efficiently and not duplicating other efforts.

“Strategic-operational” alignment refers to how well operational policies support national goals and rationales.

The alignment of a strategic policy with the realization of operational policies at a school and/or classroom level is significantly affected by the nature of an educational system, distance of implementation from the original national goal, and the context. It has been argued that alignment between national policy rationales and implementation of technology integration in teaching is not possible (Hammond 2014). One of the reasons for this is that educational technology policies are unable to fulfil the driving rationales, as digital technologies are unlikely to have a significant impact on teaching and learning themselves. Where digital technologies do affect learning and teaching is difficult to measure.

Policy and Technology Integration

The “disconnect” between educational technology-related policy and digital technology integration is well known. After several decades of educational technology policy, digital technology integration continues to be inconsistent within and between schools (Perrotta 2013). As highlighted earlier by The World Bank, there is a lack of evidence guiding leadership and teachers on how to best use digital technologies in schools and for teaching and learning. For teachers, integrating digital technologies in teaching represents a considerable change in practice and how they conceptualize learning, which has proven to be difficult. This is compounded by ongoing educational technology policy change in education resulting in change fatigue (Orlando 2014), lack of principled understanding of technology integration, and how it can be best used to support learning in their subject and learning areas (Howard and Maton 2011). Thus, schools and teachers are often unsure how new technologies will affect learning, if curriculum and assessment expectations can be met, and how to fulfil policy goals and rationales.

A Case Study

To explore how issues of policy alignment enable and constrain technology integration in a

classroom, a case study will be examined. The case study is the Australian Digital Education Revolution (DER), which was an Australian national strategic educational technology policy and part of a government education reform agenda. The underpinning rationale for the DER was that all states would receive funds: “... to achieve technology enriched learning environments to assist students to achieve high quality learning outcomes and productively contribute to our society and economy” (The Commonwealth of Australia 2009). It was initiated as a political campaign promise in 2007 and was implemented from 2008 to 2013.

The aim of the DER was for all schools to achieve a one-to-one student-to-computer ratio by the end of 2011. This national strategic policy was operationalized through three other policies. First was the provision of money to states, which is the next level down in the Australian educational system, through the National Secondary Schools Computer Fund (NSSCF). The aim of this funding was to increase students’ access to digital technology, to achieve a one-to-one student-to-computer ratio across the country. The second approach was to fund High Speed Broadband to Schools for installation of “fibre-to-the-premise”, to provide all schools with a high-speed fibre optic internet connection. The final policy was the Digital Strategy for Teachers and School Leaders initiative to fund support for teachers’ ICT professional development (Digital Education Revolution program – National Secondary Schools Computer Fund 2011).

Initially, the DER program was administered from the federal level to schools directly, through an application process. However, this became too difficult to manage and maintain accountability. Funding was then transferred to the states through a National Partnership Agreement and then distributed to schools. An audit of the program reported that by mid-2011 schools had not achieved the one-to-one ratio. Many were at 1-to-1.3 to 1-to-1.25. The audit also reported that school principals felt that the impact on teaching and learning was positive (Digital Education Revolution program – National Secondary Schools Computer Fund 2011, para 17–18). A state evaluation of the program told a different story. In one

state, all Year 9 (aged 14–16 years) students and teachers had a personal laptop, but a survey of state secondary schools showed no significant change in students' use of digital technology or a significant change in teaching practice by the end of 2011 (Howard et al. 2012).

The computers had been delivered to the schools through the NSSCF program and funds had been provided for professional learning through the Digital Strategy for Teachers and School Leaders. These represent two operational policies, related to the broader DER policy. These addressed access to digital technologies and teacher training to use the new tools in the classroom. However, the DER policy aim was to have “high quality learning outcomes” through the use of digital technologies. But at the time, there was very little structure provided from the national level to states about how to implement the initiative in their contexts. At the state level, little guidance was provided to schools and teachers on how to appropriately use the computers or what professional learning was needed to support the wider policy rationale. The reasoning for this at both the state and school level was to ensure autonomy of stakeholders to be able to enact the DER policy appropriately for their context. However, the lack of specificity on how to operationalize the policy goals and how to use the computers resulted in a range of alignment issues, which constrained integration.

Implications of Alignment

Using the DER example, it is possible to explore how educational technology policy may be enabled and constrained as a result of horizontal, vertical, and strategic-operational alignment. Specifically, the discussion will address the DER in New South Wales (NSW). NSW is one of the largest school districts in the world and chose to deliver a laptop to each Year 9 student (aged 14–16 years). Laptops were also provided to all full-time teachers. This program was evaluated between 2009 and 2013. Overall, the program was met with mixed reviews and with slow up-take across the state. Only after 4 years of having access to the laptops were significant changes in technology integration observed.

However, this change was inconsistent across schools and subject areas (Howard and Mozejko 2013). The following sections will consider why the policy did not result in stronger and more consistent impact.

Horizontal Alignment

In terms of horizontal alignment, the DER-NSW program was widely supported throughout the state and by the school department. Changes in state policy to support the DER included putting significant funds toward professional development to support teachers' technology use, such as providing face-to-face training, creating DER-specific online curriculum support and resources, having a Festival of Learning, and so on. Teachers were provided with a wide range of ways to engage in professional learning through the state education department. This suggests strong horizontal alignment between the policy and teacher training. Further, the state provided funds to increase technical support by placing laptop technicians in schools to support maintenance and management of the laptops.

However, there was a lack of alignment between the DER policy and learning, specifically the state subject area syllabi and national assessments. The subject area syllabi at the time did not include areas for digital work or integration, beyond including that students would use certain tools. For example, in science they used spreadsheets and databases. In mathematics, they used spreadsheets (BOSTES 2012). These uses tended to be quite straightforward and would not have qualified as the “high quality learning” desired as part of the national DER strategic policy. Feedback from teachers and students revealed a belief that the DER laptops were not needed for learning, particularly to do well on assessments. In many cases, the laptop was even seen as a detriment to learning (Howard and Mozejko 2013). Without technology integration as a priority in subject area teaching, curriculum, and assessment, horizontal alignment was not strong even with good alignment in other areas. This was a significant contributor to the policy having minimal impact on teacher practice and was of little benefit to schools (e.g., Kozma 2008).

Vertical Alignment

Vertical alignment of resources from national to state to school levels was visible and well managed. In many cases, teachers felt pressure to use the laptops because of the significant government investment, national policy, and availability of DER professional learning opportunities (Howard and Mozejko 2013). Research has shown that this kind of pressure can be a strong catalyst for teachers to adopt and integrate digital technologies in their practice (e.g., Zhao and Frank 2003). However, at the time of the DER, there was considerable fluctuation in the national government and significant ambiguity if national funding of the DER would continue, year to year. Moreover, the state did not commit to continuing the DER if national funding ceased to be available. This left schools and teachers with a feeling of limbo about the program and if it would continue. This significantly affected how much time and energy they were willing to invest in new teaching strategies and creating integrated lesson plans at the subject level (Howard and Mozejko 2013). Therefore, while there was actual strong vertical alignment, stakeholders perceived weak alignment resulting from a lack of government commitment, which impacted on their willingness to change their teaching practice and significantly engage in the DER program.

Strategic-Operational Alignment

The DER was fairly typical of large-scale government implementation of one-to-one computer programs, in that there were relatively clear connections between strategic and operational educational technology policies. Similar programs at the time were the Maine Learning Technology Initiative (Silvernail and Gritter 2007), Michigan Freedom to Learn (Lowther et al. 2012) program, and the Berkshire Wireless Learning Initiative in Massachusetts (Bebell and Kay 2010) in the United States. All of these programs were based on the rationale that increasing access to technology would also promote high quality learning through the use of new and modern tools. The three national DER operational policies provided explicit support to achieve the national goals by providing funding for computers,

infrastructure, and teacher training. This has also been the approach in other one-to-one programs. All three of these are necessary for technology integration to occur and for policy to have an impact on teaching and learning. However, this also reflects a historic trend of noncritical treatment of digital technology integration and a general assumption that use of technology will result in learning (e.g., Bayne 2015; Beynon and Mackay 1989; Hammond 2014).

Research has shown that there are gains in learning when digital technologies are used in the classroom, but there is very little understanding as to why or how this happens (e.g., Skryabin et al. 2015; Tamim et al. 2011). Effective uses of digital technologies are those that support teachers and students reaching desired learning goals (Tamim et al. 2011). Learning goals will differ between subject areas, as will conventions of teaching, the types of skills and content knowledge students must acquire, and their assessments. As little is known about how technology integration positively affects learning, there is even less understanding of how to connect technology integration to wider policy rationales and goals (Hammond 2014). Goals related to teaching and learning will naturally differ from those used as policy rationalizations.

The problem is that strategic and operational policies have tended to treat technology integration as a homogenous practice (e.g., Howard et al. 2015b). Little attention is paid to the specifics of teaching within subject areas and how learning goals are achieved, which has significant implications for the enactment of those policies. For example, in the DER, providing teacher training was one of the main operational policies. In NSW, that teacher training often promoted a student-centered and project-based approach to learning (Howard and Maton 2011). This aligned with subject areas such as English and history, less with science and it was at odds with mathematics (Howard 2011). Teachers who were not comfortable with using a student-centered approach in their classroom felt that digital technologies were not necessary for their teaching or were uncomfortable using computers. They would often make the argument “that’s not how we do

it” or “that’s not how we teach” in their subject area (e.g., Howard 2013). Therefore, while there may have been alignment between strategic and operational policies in the DER, both lacked alignment with teaching and learning. This resulted in the policy having little impact on teaching and learning, and even having a negative impact on teachers’ willingness to engage with technology integration.

Progress and Conclusions

It is known that students need to be using digital technologies in sophisticated ways to prepare them for future work and learning (Helsper and Reisdorf 2016). However, the complexity of educational change and technology integration makes it difficult to identify why many educational technology policies fail to have significant impact in education. In the example presented here, there are a range of areas that need better alignment, such as the dependability of resources to fund the DER program from national to state to schools, which constrained teachers’ willingness to engage in the initiative. However, what really matters to teachers in technology integration is learning (Ertmer and Ottenbreit-Leftwich 2010; Howard 2013). For many teachers, the conception of learning is within the scope of their subject area or the key learning area they are teaching. By and large, they will stay with their known and successful approaches to teaching and learning, rather than put learning at risk by using new digital technologies.

For policy rationales to be attained, stronger alignment with subject area learning goals is essential. This approach would increase alignment and create a direct connection between teaching and policy aims. As a step toward improving the impact of educational technology policy, many countries have started to embed digital literacy, medial literacy, and so on, in curriculum documents. In Australia, the Australian National Curriculum contains an Information and Communication Technologies (ICTs) General Capability. This provides a framework for what students need to know about and how they should

work with digital technologies (ACARA 2012). The operationalization of curriculum in state subject area syllabi creates a direct connection between learning goals and rationales for national educational technology policy.

Other areas of development, such as school leaders fostering a culture of experimentation and more personalized professional learning opportunities, are needed to support teachers in their own school contexts to integrate digital technologies. For example, while many teacher training options offered as part of the DER were focused on specific subject areas or teaching contexts, they were segmented from the classroom. Teachers need to test and trial new digital technologies in their own teaching, to adapt and pedagogize with their own students (Hammond 2014; Tondeur et al. 2013). Building this level of support at the school level, into operationalized educational technology policy, would strengthen alignment and improve the impact of policy in teaching and learning.

Positioning Children with Digital Interactive to Enable Early Conceptual Learning

Cheryl Jakab and Christine Redman
Melbourne Graduate School of Education,
University of Melbourne, Melbourne, VIC,
Australia

Definitions

Positioning theory highlights that what learners can make of concepts is dependent on the support they are given. Digital interactives are representations using combinations of words, images, sounds, and symbols that can provide support for learner use of concepts by giving feedback or

requiring responses, action, or input from users as they interact those conceptual representations. Digital interactives are thus changing how children can be positioned with concepts, what concepts they can learn, and what young learners can do with those concepts.

Introduction

What children can learn is dependent not only on their age or what some see as their stage of development but, significantly, also on the resources the culture they find themselves in makes available to them and how they are positioned with those resources by their more experienced others. Today, toward the end of the second decade of the twenty-first-century talk of molecules, DNA, gene editing, nano-materials, black holes, the World Wide Web, and Google Earth are ever present. These ideas are facts of culture that are changing the everyday lives of adults and children alike in our ICT-rich world. Such material resources can influence what can be considered intuitive for young children. What they make of these ideas is dependent on the support they are given to make use of the resources – how they are positioned with the ideas.

As Google turns 20 years old, in 2018, adding digital tools to the bank of resources shared with young children is not, as yet, commonly accepted practice in the early years. This is so despite today’s virtual reality digital tools putting the Earth, and other “abstract” concepts, at their fingertips in everyday life, figuratively and literally. Such interactive artifacts can and are changing the way many problems in learning are coded. In this the example used as a focus for the discussion is what is known as the *scale of things*, stuff, from molecules to planets. The presence of these artifacts has important implications for what young children will experience in their everyday life and demand a reconsideration of what is suitable in early years of educational experiences.

Digital interactives sharing molecules and atoms and the Earth as a planet in space are cultural tools of today that can and are being designed with young children in mind. Interactives with scientific ideas of *stuff*, atoms

and molecules, through to planets, stars, and galaxies, from the nanoscale through to the cosmic view, are today readily available, in the everyday world of the twenty-first-century young child. However according to National Curriculum guidelines across the globe, these ideas are not a part of the formal science education until later in schooling. Progress in understanding the power of digital interactives as cognitive tools for young children's development of theoretical concepts, specifically in chemistry and astronomy, across the scale of things, has been explored by a few researchers using positioning theory (Jakab 2013a, b; Jakab and Redman 2017).

Outlined in this entry is support from this research for ICT enabling an earlier *offering of* scientific ideas to young children than was previously considered possible, due to the interactive representations changing the accessibility of concepts for young learners. While this may be so for any concept that a society finds valuable for children to learn, this entry focuses on the early offering of two *big ideas* of science, *the particulate nature of matter* and *the earth as a planet in space*. Current curriculum guideline worldwide recommends delaying the offering of these concepts until middle years or later in schooling (ACARA n.d.) due to the abstract nature of the concepts. This entry explores how an earlier offering can better position young learners for more scientific *ways of seeing and being* in the world, supporting their future positive scientific *habitus* (Burkitt 2002). Evidence for this early offering of concepts through ICT is scant in the literature. A review of the arguments and evidence for providing an earlier groundwork through supporting younger children to *know of* these concepts supports the notion that directing developmental thinking toward the science concepts can minimize many of the alternate conceptions that have long plagued chemistry and astronomy education (Kind 2004; Vosniadou 2008).

Today's games, visualizations, and simulations can provide access to ideas from atoms to planets and galaxies to all age groups. Given that situational factors, such as cultural artifacts, past experience, and cultural norms, limit and direct what children can know and do (Siegal 2008), this

entry raises questions about how the use of ICT visualizations and interactives by young children can more effectively open possibilities of *thinking with* key science concepts.

Exploring Today

Interactives are now available to play and explore any aspect of the world of human knowledge any explorer can think of. An everyday experience watching young children at this tells the observant parent or educator that even the very youngest of today's digitally *connected* children are exploring concepts that until recently would have been thought too complex for them to contemplate, for example, when using a touch phone or tablet to "go" from their home to outer space and back again. Observation of such activity also shows that the child participating in such activity is indeed learning. Today feedback from suitable interactive, not just a human carer or teacher, provides reinforcement of certain activities and constrains others. What works is evident in what happens. Associations are formed. The activity does not confuse. "Real world" and virtual worlds are both experiential and afford certain activities, knowledge, skills, and patterning. Children learn from the activity. In some cases they enjoy and persist if they are intrigued by the possibilities. Through trial and error, a young baby given such a tool will learn to use it. In this entry this activity is likened to what Barbara Rogoff (2003) described, when she observed that a 2-year-old child in a culture where a significant tool is a machete, they can begin to learn to use that cultural tool when positively positioned with it. It is just how the world works. In this sociocultural approach, the tool affords the experience. Experience with the tool builds know-how and then with time becomes incorporated into *habitus*.

Traditional View of What Children Have to Play with

The commonly accepted approach to content in early childhood education is to focus on firsthand

experience in the physical world (Sacks et al. 2011). The emphasis in science learning for young children is playful experience, often contrasted with a focus on information or concept offering (outside that contacted in daily life).

In early childhood science education, observation, classification, and description in this playful experience with physical materials, as compared to conceptual knowledge teaching, have long been emphasized as better supporting early development. The two are put in opposition. Taking a cultural tool view, this approach, that of not offering science conceptual knowledge, privileges traditional everyday concepts, those that are offered in everyday life as commonplace to share with children. But what is missing from this approach is acknowledgment that what is commonplace is not fixed. As culture changes so too do everyday concepts and commonplace knowledge and, importantly here, what can be made clear, concrete, and easily represented.

What Is Play?

As described by Pui-Wah and Stimpson (2004), play is often “treated as ‘free play’ with no learning intentions. It was a reward or a time for the children to relax after their ‘work’” (p. 343). This idea of play is often contrasted with intentional teaching. By taking a more sociocultural approach to the availability of cognitive tools, including ICT tools such as interactives such as Google Earth or molecule building games, the ideas that are shared and available for playing with are culturally determined. These form the funds of knowledge (Hedges et al. 2011) that background the developing interests of children growing up in a society. But these funds of knowledge are not fixed and are culturally dependent. What the educator, parent, or social other focuses on is what any child then has available to “play” with. This acknowledges that what has been culturally shared with the child directs their ways of thinking and being in the world, their future ways of thinking, their *habitus*.

Exposure to fiction and imaginative stories is accepted as vital for young children’s growth

(Scott 1998; Vygotsky 2004). The ability to represent is enhanced by imaginative play, in which one object is made to represent another. Use of culturally accepted ways of doing and saying are rehearsed in such interactive play experiences.

There is ample support for the notion that what is accepted as developmentally appropriate practices, in early years and early schooling, underestimates what children today can do and know (Siegal 2008). What a young child can achieve, do, and know is now acknowledged as dependent on their positioning with ideas and practices (Howie 1999): what a child (or indeed any learner) can do or know in a situation is dependent on how they are situated and positioned in the situation. The material and social resources at hand at the time and their rights and duties in the situation direct development. This conceptualization of learning emphasizes that a learner’s engagement and achievements are not only dependent on their personal history and internal cognitive states (prepositioning); the thinking tools made available for exploration will change what is possible (Rogoff 2003) and the trajectories that will be enacted. The changing teachability and learnability of concepts due to ICT is a current major area of research, mostly at secondary and tertiary levels. What was once unlearnable using previously available thinking tools can now be far more learnable (Noss 2012). This is so for all people – scientists and young children – alike dependent on what resources they have at hand.

Playing with Science

Young children enjoy *playing* with science. The science they are encouraged to enjoy today in early childhood and early school years is reasonably described as hands-on exploration, with *concrete* materials rather than *abstract* ideas. The offering of abstractions in teaching, big ideas, or major theories is routinely held back until secondary level of schooling due to what might be labelled *fears of misconceptions*, which have also been associated with a lack of interest in science in later years (Alexander et al. 2012). Currently what science is for young

children is based around processes of observing and describing, with conceptual knowledge offering being limited to that in their everyday world.

This approach has been in place in curriculum guidelines for over 50 years. While today there is arguably more emphasis on science in early years curriculum than previous times, the nature of that science is still very much the same, focused on sensory exploration and description of events in the world of our senses. At the same time, an ever-increasing public disengagement with science is well documented (Archer et al. 2012).

Digital Interactives as Everyday Artifacts

Along with changing daily life, digital technologies present many challenges to education across all levels in the twenty-first-century. A flurry of education research has ensued, as is evidenced in the broad range of explorations offered in this encyclopedia. This entry explores a lesser researched aspect of the challenges being faced (Smetana and Bell 2012), the changing nature to what is “intuitive” for young children today, through the experiences afforded (Gibson 1979) by digital tools, for those growing up in twenty-first-century computer-assisted societies. A small number of researchers taking a sociocultural perspective on development and learning are highlighting the need to reconsider the age-/stage-derived idea that concepts can be considered *abstract in and of themselves*, by acknowledging that learning is performative (Arievitch 2007; Saljö 2010).

Digital interactives are now commonplace everyday *cultural artifacts* (Lidar et al. 2009) available to even the youngest members of ICT-rich societies. As anyone who has watched a 3- or 4-year-old child *play* with Google Earth will know, zooming in and out – from the local area to off Earth – can be fun and of interest and offer the child both physical experience with using the technology and ideas about the Earth as a planet in space. When suitable social support is provided to encourage such thinking, what is possible for

a young child in terms of their conceptual development?

There is a very easy way to observe firsthand that *what is intuitive* for a child (or adult) is culturally dependent, as compared to there being some base set of unchanging phenomenological primitives that underpin experience. Offer a screen to a twenty-first-century very young child. What interaction with this tool would you expect from a 1-, 2-, 3- or 4-year-olds? The likely response is a tap or swipe with a finger across the screen. The child has set out on a trial-and-error exploration of what happens when the screen is tapped in different places. Causal links are made.

Exploring Early Development with Digital Tools

One change that has occurred in schools that is working its way into the curriculum due to the changing times is teaching coding to very young children, which effectively establishes a grounding for future coding work (for those going on in the field) and a more ICT literate general public in the future (for those who do not). Another change is use of touch screens and personal devices for better communication in both mainstream schooling and for a range of students with special needs. Many changes to conceptual learning in science education with the use of digital tools is occurring; however the majority of the research is being conducted at secondary and higher levels (Smetana and Bell 2012). The proposition that twenty-first-century digital interactives can be effective tools in supporting and redirecting younger children’s conceptual developmental trajectories has had less attention in the literature to date.

Matter and Space: Abstract Concept or Conceptual Tools

Prior to the digital revolution, extensive research programs have been conducted over decades, documenting the problems school children have

with science learning, particularly the nature of the *stuff* of the universe. Summaries of the research into learning issues in the topics of interest here are available: for the concept of particulate nature of matter (Kind 2004; Skamp 2011) and astronomical thinking, in both conceptual change (Vosniadou 2008) and sociocultural approaches (Ehrlén 2008; Jakab and Redman 2017). The proposition that digital interactives can be used to help make concepts routinely labelled *abstract*, such as particles and planets, more accessible earlier in education, is an important though somewhat neglected topic ripe for exploration in this digital tool era. At this time, the idea that digital interactives are changing the learnability (Noss 2012) of concepts for young children is beginning to gain some momentum.

There is mounting evidence that young children are getting greater exposure to some concepts in everyday life than is supported in early years education. That such *funds of knowledge* can support a more scientific *habitus* (Sikdar and Fler 2015) is less well established. Could conceptual development be better supported by acknowledging that children can know and do far more than previously considered possible due to the educational opportunity that current technologies hold for visualizing and supporting exploration of concepts?

History of Representing the Scale of Things

Long before such digital interactives were extant, over 60 years ago, in 1957, a groundbreaking book by Kees Boeke was published – *Cosmic View: The Universe in 40 Jumps*. This little book offered the *scale of things*, from the human to that of the universe, in a combination of representations available at that time, in illustrations and words, to make concrete for adult learners “40 jumps” in scale. That book was made into a 9-minute color movie by Charles and Ray Eames, in 1977, using the best imaging tools available at that time. The film made *thinking with* the scale of

things far more accessible for the viewer at that time. While not an everyday concept for the wider public, the idea was thus supported in entering common knowledge.

The cosmic view is powerful and important to conceptualize for scientifically literate in twenty-first-century society. Using the scale of things helps a person to orient himself when thinking about the nano-world of atoms and molecules, cellular level of DNA, viruses, and microbes, through to the distances across the Earth’s surface and the vastness of space. Today’s digital interactive tools, such as Google Earth, are ubiquitous, so that zooming in and out has become a popular game-thing for even the youngest of the “connected” generation to play with.

In 1998 the importance of the *Powers of Ten* film was acknowledged as culturally, historically, or aesthetically significant, awarding it a place in the United States National Film Registry. Today, this short film and other versions demonstrating the same embedded concepts are readily available online for anyone to peruse for themselves on personal digital devices, anytime, anywhere. These interactive representations bring to our screens the possibility of *knowing of*, playing, and working with *the cosmic view*.

The Scale of Things Today

Today an online search of the term *The Scale of Things* will produce a huge array of hyperlinks for the searcher to choose from, each of which can lead to a further wealth of resources to explore, helping to visualize complex concepts, making them more concrete. The scale of things can still be difficult to grasp fully and use accurately, for experts as well as novices.

The digital tools being developed for everyday use such as Google Earth can help with the meaning-making about the *scale of things in the world*. They are useful conceptual tools for everyone, scientists and children. Making use of such tools can provide meaning-making experience on which a more scientific *habitus* can be grounded.

As described by Leontiev “The human tool is not just an object with certain physical properties. It is a sociocultural object, an object in which historically developed operations are embedded” (quoted by Arieievitch 2007).

Children and Digital Tools

In exploring the literature in this area of the interactions of young children with abstract science concept development, a tacit assumption is found in many articles: that science (abstract theoretical) conceptual knowledge is best developed at secondary school level. For example, a recent review of computer simulation use in science learning literature, Rutten et al. (2012) proclaim: “We focused on students from 12 to 20 years old, as these are the most important years for the acquisition of basic scientific knowledge” (p. 137). This sentiment is widespread and supported in National Curriculum statements across the globe.

Concurrently science is ever more important in daily life, and ICT is affording ever-increasing opportunities for exposure to abstract concepts, scientific, and otherwise, from a young age. The long road to fully understanding any concept however begins with first steps, what is described by Jakab (2013a) as a first *knowing of*.

Early Learning About Matter

Currently the dominant mode of opening scientific discussions of what is matter with young children in curriculum designs is to start first with macro-world sensory phenomenal description of physical materials and then consider physical change and chemical changes as observed with our senses. This descriptive work in science learning is currently being carried out by young children with the support of adults in their everyday and school learning to help them construct meaning, without reference to atoms and molecules, the dominant scientific basis of chemistry, what might be described as the particles toolkit.

The study of children’s (pre-)conceptions of matter, substances, solids, liquids, and gases based on a set of everyday uses of these words is

extensive (Skamp 2011). But what can happen to this learning trajectory when more scientifically sophisticated ideas are shared earlier? What intuitive notions or everyday preconceptions are displayed today?

By offering young children the very idea that matter (in normal conditions on Earth) is particulate, many of the alternate conceptions described in the literature as prevalent can be avoided. Specifically the idea that matter is continuous does not need to underpin everyday experience, as providing particle concepts earlier can eliminate this alternate conception.

Decades ago, Novak explored the use of multimedia to offer young children the concept of the particulate nature of matter. The conceptualizing tools available when Novak designed his intervention included use of taped lessons and recorded images. The results of a 12-year longitudinal study of the science concept learning when early years students were given one intervention about particles showed a lasting benefit of the intervention, with students doing better in late secondary school chemistry than their counterparts (Novak 2005). Despite this research showing clearly positive results, there has been no concomitant change in curricula designs in chemistry for young children. The documentation of children’s alternative to the scientific concepts, so-called misconceptions, continues. Particle ideas are often named more of a problem than a solution to children’s chemistry learning (Skamp 2011). These problems evidenced in the literature for decades show little sign of being reversed with current practices. As Kind expressed the problem remains. How can chemistry learners be better supported to *see with molecular spectacles*.

Cultural Support for Molecules

Today’s visualizing tools are far more sophisticated and interactive. One of the well-designed site freely available for any young child to play with is at the Molecularium (The Molecularium project 2004). The Build game at this site focuses on the proposition that molecules are built with atoms. Children playing this game have been shown to raise scientifically sophisticated

questions about particles of matter (Jakab 2013a, b). The research highlights that when offered the opportunity to know of particles, young children express knowledge of molecules and atoms from everyday life – from television, newspapers, museums, and stories. They raise scientifically appropriate questions about the concepts and, importantly, show interest in learning the concepts through sustained interest in questions raised. The pathway to expert use from the early novice starting point of such particle representations in explaining “stuff” is a long road that necessarily starts with the tottering first steps of the novice (Jakab 2013a, b).

What the children did with the offered knowledge was intertwined with two factors: firstly, what the interactive supported them in doing and, secondly, the social feedback given for their actions. Positive positioning by the more expert social other in this research extended their questioning and helped support their beginning interests in more scientifically profitable directions. This positive positioning of the child with chemistry concepts as they explored with the digital interactive provided experience with the words, images, and relationships important in science about the particulate world. The very existence of molecules and atoms was new knowledge for some of the young research participants, though the majority of the 6–12-year-old study participants had some everyday knowledge of atoms and molecules from daily experience in life – television, books, stories, and news items. The offering of the words and the progress through the interactive positively positioned them with particles ideas as new tools to use in their thinking. The particle level and the symbols in chemistry are combined in the Molecularium Build game, along with information about the physical substances.

This first *knowing of* the concepts using the interactive opens the door to more sophisticated scientific thinking. It provides the groundwork that allows progress toward further knowledge and use of that knowledge. The children were able to make use of the concept for their thinking in scientifically profitable directions, and, importantly, interest was created for the young learners,

for example, wondering what a molecule could be. The knowledge being shared can go far beyond what young children in the past could have had access to, in a large part, due to the ready availability ICT, and in high-quality filming of the natural world. Today’s science factual storytelling is being supported by visualizations, animations, and interactive games that young children can readily use for their own purposes.

Such first steps might be described as *performance before competence*, which is highlighted in cultural approaches to understandings of human development, as a valid stage in learning (Rogoff 2003; Cazden 1997). Sociocultural theory directs attention to the central role of interaction with more expert others in supporting higher mental functions. Only after this mediation through supported interaction or scaffolding by a more expert other will the activity become independently performed by the individual, using their own mental resources (Vygotsky 1987; Wertsch 1997).

The research by Jakab and Redman (Jakab 2013a, b; Jakab and Redman 2017) addresses the challenges presented to education with the changing cultural landscape presented by digital technologies. Their research explores what children growing up with these tools available are afforded, when the child research participants were positioned with suitable digital interactives to offer the possibility of enabling earlier conceptual learning (The Molecularium project 2004). The *building* of molecules from atoms of carbon, hydrogen, and oxygen offered in the *Nanolab Build* game offered opportunity to explore the central proposition of chemistry: *molecules are built of atoms*. The children showed interest and curiosity about the concepts achieved in the trial-and-error efforts and asked scientifically sophisticated questions. Importantly the children in this small study, aged 6–11 years old, thought that these ideas should be offered to children “before 8 years old.”

How did these digital cultural tools change possibilities for learner’s conceptual development? They provide thinking tools to change what might be intuitive or phenomenologically effective to do and think in the situation. In

contrast to most works exploring challenges posed by technology to education, this research probes the changing possibilities of learning concepts in early childhood and early school years in the *zone of proximal development*. In contrast to the majority of research conducted so far in changes to learning of conceptual knowledge, the research discussed here afforded by technology focus on secondary and tertiary student levels when using computer-aided simulations, as summarized in 2012 by Smetana and Bell (p. 1343) in sciences. While the entry focuses on early learning, many of the points raised could also inform researcher thinking about the changing nature of concept teaching possibilities for all ages. The research and approaches described here extend on the idea of *pedagogical link-making as defined* by Scott, Mortimer, and Ametller (2011). Taking a neo-Vygotskian view, this is the external presenting the extent of expert understanding of the proposition that an initial step in learning concepts can be described as a first “knowing of” a concept and can be better offered through well-designed ICT. This positioning young children with a concept using ICT, with its rich combinations of words, images, animations, and symbols and interactive facilities, is not just changing the teachability and learnability of concepts for older students and adults, but redefining what might be considered developmentally appropriate for younger children.

Learning About Earth with Visualization Tools

Privileging one tool above another necessarily shapes the ways individuals can represent phenomena and come to solve posed tasks. When thinking about ideas of the Earth, what tools are we putting in the hands of young children?

Conceptual change research (CCR) has documented many problems students have with the scientific concept of the Earth using clinical style interviews as research tools (Vosniadou 2008). These interviews require the child to

provide answers using their own resources. If however very young children are provided with an Earth globe as a material resource when interviewed about their understandings, taking a more sociocultural approach to what comes out of interviews, many of the problems documented in what the children say do not appear. Schoultz et al. (2001) conducted their research interviews with a small Earth model in the room, so the child was positioned with the tool to aid and direct their thinking. Indeed today, with the everyday presence and easy access to Google Earth and satellite imaging, the problem for the child is changed. Even the youngest members of our society are exposed to numerous images of the Earth as a planet in space in daily life and can “play” with changing scales of images, getting immediate feedback to their actions.

A swiping action with a finger to zoom in and out magnification when looking at images of the surface of the Earth (on a screen) might have seemed strange in the recent past, though testing physical objects by banging, biting, dropping, scratching, and cuddling has always been what babies and young children do to find out what happens, what works through interacting with the world. By constant trials children learn the differences between appearance and reality and not confused by such differences (see “Kids, Appearance, and Reality” in Siegal for an excellent summary of this work). What will occur when any object is offered to a child depends on their past experience with that offered object. By testing the uses that an object can be put to, its affordances, the child explorer develops understanding of how their world works. Testing the affordances of any physical object established a multiplicity of uses and possibilities.

In learning to speak, the affordances of a word are made through affordances of the utterance of the sound. The affordances of an action discovered in the doing. The world the child finds themselves in, of objects, words, images, and actions, is explored through what they afford, “what works, how, and when.” The digital world is another world to explore, a virtual reality, another world that offers different experiences from those

in the physical world, but relate to it, and can be explored to provide experience that can be interlinked with physical action and mental activity.

Swiping with a finger across a screen to activate a phone or touch pad, for example, is today a culturally appropriate action that is reinforced as it affords certain outcomes, based on situated experience with ICT tools. Such action is not a universal intuitive preconception. It is *know-how* with digital tools, as any other tool, built through experimentation in a virtual world, the same as it is in physical world. The expectation that a finger swipe action will produce a result on a screen is based on experience. The act of a finger swiping across an offered screen directs the carer's attention to the fact that the child has been afforded a response to such action with such devices in the past. Indeed, today many of us will acknowledge we have found ourselves making that "intuitive" swiping action on non-interactive screens, such as non-touch computer screens, mechanical cooktop controls, and even analogue watches.

Today digital interactives are a set of cultural tools that are constantly being refined and upgraded and ever more accessible and available for even the youngest human to interact with and experience as part of their everyday world.

Making use of Google Earth to explore the Earth affords the young learner with a big current cultural assumption that "the Earth is a planet in space." This is a hinge concept, providing a basis, acting as the ground on which Earth and space ideas can be explored scientifically. If it is provided as a certainty, from earliest years, with images of our planet, one of the great icons of our time, the child moves forward from that accepted known. With a first knowing of from a young age, the concept can be explored, questioned, understood, and used as a starting point for our being in the world.

Positives of Taking a Sociocultural Perspective on Learning

The great value of taking a more sociocultural approach to the conceptualization of the issue

under discussion here lies in appreciating that what is developmentally possible is not fixed, but rather what is developmentally appropriate is culturally and historically dependent. As described by Rogoff (2003): "This perspective has shifted our understanding of cognition from a focus solely on the thoughts of supposedly solitary individuals to a focus on the active processes of individuals, whether momentarily solo or in ensembles, as they engage in shared endeavours in cultural communities. [] Cognitive development is an aspect of the transformation of people's participation in sociocultural activities" (p. 237).

The differences between the individualistic constructivist conceptual change and sociocultural approaches to conceptual development have been contrasted by a number of researchers. Taking a pragmatists view of meaning-making (Lidar et al. 2009) provides opportunity to explore the challenges that changing culture can make to learning progressions.

In exploring the literature in this area of the interactions of young children with abstract science concept development, a tacit assumption is found in many articles: that science (abstract theoretical) conceptual knowledge is best developed at secondary school level. For example, in a review of computer simulation use in science learning literature, Rutten and van Joolingen et al. (2012) state: "[W]e focused on students from 12 to 20 years old, as these are the most important years for the acquisition of basic scientific knowledge" (p. 137). This sentiment is widespread and supported in many National Curriculum statements.

An alternate view is that not offering concepts may encourage developmental thinking in less desirable directions, toward everyday or folk ideas and away from the more scientific. Development of a positive science *habitus* is more likely when there is an exposure to processes and key concepts of science as tools for thinking. Constraining thinking toward the science concepts is a productive use of science teaching time. In exploring early use of molecule concepts, for example, an initial "knowing of" the ideas

provides a basis for ongoing refinement of the learners “knowing how,” and “knowing that” with these ideas (tool-use combination) is seen as a process of change in thinking over time (Jakab 2013a, b).

Culture aids development in three main ways, through the social supports that are given, participation in everyday activities, and in the cultural tools or artifacts that are available (Gauvain et al. 2011; Stahl 2012). Thus rather than a universal or fixed developmental progression from intuitive preconceptions or phenomenological primitives, what is *intuitive* is dependent on experience, as outlined in the ecological approach concept of affordances (Gibson 1979). Taking a more pragmatic view of development allows for cultural everyday experience, material tool availability, and support of others in sharing accepted ways of being and doing, to lead and direct development. Adding culture to study of development in tentry-first-century child allows for the changing possibilities according to the availability of digital interactive artifacts.

Sociocultural researchers are thus asking: What is *intuitive* for a digital world child today? What is now possible by doing and achieving with digital tools? Just as any other tool, a book, a fork, numbers, doors, etc., what a tool affords depends on its availability for use of the learner along with the social supports the learner has when using it. With time, increasing knowledge about and how to use the tool, that tool can become part of the person’s toolbox, what they habitually use or bring to hand when needed (Gauvain et al. 2011).

Conclusions

There is considerable research showing that digital visualization and simulation technologies are changing the teachability and learnability (Noss 2012) of ideas previously accepted as highly “abstract” concepts. Many of these so-called “abstractions” are held back to later years of schooling, including the particulate nature of matter and ideas of scale as they are considered too *abstract* and difficult for younger children to work with.

A small body of research supports the notion that positive positioning of young learners with concepts, using currently available ICT visualizations and interactives, does enable or leverage young learner interest toward and taking on a more scientifically sophisticated *habitus*. A limited range of research articles published indicate that the provision of key scientific language, images, animations, and visualizations with ICT tools can support young learners to positively *know of* and engage with concepts – including the particulate nature of matter, gravity, and the Earth as a planet in space. This *knowing of* the concept, as a first step, can subsequently lead to opportunities to know more about and do more with the concept, thus leading to an increase in a positive disposition and engagement with the meaning-making about and with the concepts.

The tentry-first-century everyday cultural tools afforded by the rise of ICT can change the way a child visualizes, presents, and represents many concepts. The very idea of size and distance can move from what they were once (considered), that is, difficult and “too abstract” an idea for most people to imagine, to today being a concrete activity that even the youngest independent human can experience in the virtual world, when provided with suitable support. Young children today are exploring the Earth, molecules, genes, germs, viruses, ocean depths, black holes, the universe, and so on. They are developing everyday knowledge about and importantly can acquire skills with these concepts, using digital devices and a set of virtual thinking tools. Ideas such as “humans live on a small blue dot in the vastness of space” (Redman 2004) down to the structure of DNA molecules, the arrangement of atoms of say in water at different temperatures (Molecularium), and manipulation of subatomic particles to create atoms in a game or in a lab are accessible realities for today’s children, adults, and scientists.

Understanding how ICT tools and digital interactives can and are changing what is in the everyday experience of children will help us better understand what is *intuitive* for children today and how the concepts we want to be built into person’s *habitus* (Burkitt) can better be supported. Offering books to babies was once

considered unnecessary but was shown to rapidly increase literacy rates. Offering reading as a valued tool, allowing experience with the tool in books for babies, reading to babies and toddlers, showing that reading was valued and providing social support for reading, turned reading (and also writing) into everyday activities that a child experienced before they were competent with the tool. Performance before competence is an important step in learning.

In the research cited above, when positively positioned with “the idea,” the ground is prepared, affording a young child the possibility of learning experiences that are in line with, or constrained toward, more scientifically sophisticated “ways of seeing.” In this way, the ground for first knowing of the idea is prepared.

The great power of digital interactives as educational tools is that they can offer complex concepts in suitable combinations of words, images, and symbols in multimedia and interactive formats, providing representations and interactive experiences including instant feedback, which can act as a grounding for a better initial understanding of ideas that in other noninteractive formats – drawings, writings, and even moving images – could be difficult for the novice to manipulate and rehearse accurately. The digital interactive format can better position a person, be they child or adult, to begin the process of “seeing what might be” and providing instant feedback that is differentiated for the specific learner needs and their mastery of specific challenges. Digital interactive tools can embed current understandings and in their use *open the door* to new ways of seeing. They can also inspire the person to move forward in exploring of the interactive, be it a game or other format, with a sense of anticipation.

Implications for Early Childhood Education

We must take a positive stance in facing the contemporary challenges that arise about what is accepted as most suitable in science curriculum, following the tradition of curricular change

suggestions based in both changing theoretical understanding and cultural change. A revisiting of what children can do and know today, when they are positively positioned with digital interactive devices, is called for at this time in history, to explore what children can know and do in this ICT-enabled world.

A plausible way ahead to supporting more scientific conceptual thinking, with science or other concepts, is to provide ICT experiences that allow an early first *knowing of* and exploration when a child shows interest. Asking questions about the conceptual tools is a step to better knowing, even for the youngest children. A fear of misconception development has perhaps got in the way of opportunities to “know of” key scientific ideas earlier in learning progressions.

As the researchers exploring the Molecularium with young children conclude (Jakab and Redman 2017): “chemical educators would do well to acknowledge that current visualisations are changing ‘learn-ability’ and can support more scientifically accurate and more sophisticated chemical thinking at a younger age than occurs in current practices. One of the benefits of an earlier introduction would be a decrease in conceptual load seen in senior secondary chemistry, by giving learners more time to appropriate the ideas and develop more habitual and expert uses of and with all three levels of chemical thinking (p. 11).”

At this point in time, it is vital that National Curriculum guidelines, such as Australia’s (ACARA n.d.), are questioned and revisited, in terms of what key ideas and concepts can and should be offered to young children with the use of ICT tools. Digital interactives can better position children for a first *knowing of* and subsequent taking on of key concepts into their habitus earlier than using previously available tools for thinking. Working with these ideas allows interest in science ideas to lead (as compared to follow) develop. Perhaps many of the disengagement problems and alternate conceptions developments that have been long identified could be averted. A better sharing of the scientific view of the nature of *stuff* in the universe using ICT is possible. The last word is left to a year 10 chemistry

student: “I think kids in kinder should be singing songs about the periodic table. That would help ...that’s what I think. I shouldn’t be struggling to remember it now – it should already be part of what I know” (Jakab 2013a).

Positive Integration of ICT to Reshape the Learning Process in Large Corporates

Quazi Omar Faruq

Pathfill Training, Broadmeadows, VIC, Australia

Learning at Workplace

Even after recruiting best people from job-seekers, many organizations need to train people for several reasons: to blend human resource with the policy and procedures of an organization, updating knowledge with current work environment, market change, and changing demand for service. Adaptation to the rapidly changing market with a view to maintain competitive advantage in the industry warrants specific training over time. Increased competition due to globalization is another impetus for frequent updates of operational aspect of an organization, needing upskilling human resource, mostly by training.

Learning in small or medium organizations is not very difficult as frequent face-to-face interaction helps transmission of knowledge. In large organizations like corporate, it is a challenge particularly with workstations widely dispersed and information or technology need to be disseminated within a set time.

Up to the last quarter of nineteenth century, most corporates arranged training for human resources by hiring attractive venues, bringing renowned speakers or successful business figures, and spending fund for incentives. Training rooms were considered top grade if fitted with projectors and other audio-visual devices and assessments were mostly classroom-based.

Updating knowledge of the human resource in a large organization with widely dispersed working areas, diverse work role, and sometimes with only a few people in one specific operational area is a challenge. It might be possible to conduct the induction training at a center but not for ongoing issues. Learning needs in the corporate vary. One study suggests most needs are focused on service (27%), sales (22%), technical (21%), other (20%), and regulation (10%) (Merkel and Cohen 2015). It also mentioned that most learners used the presentations on the topic, in the repository, to improve their learning compared to the lesson plan or software simulation.

Today, digitalization with the support of broadband internet is rapidly changing the mode of training. Development of webpage and access through membership is the turning point of disseminating knowledge among human resource. To improve the quality of human resource in a corporate, the word “training” does not fit rather it should be replaced by the word “learning” and more precisely “continuous learning.” In some organizations, it is “learning and development” (L&D). Most learning is now web-based learning or E-learning (Nicholson 2007). Updating knowledge is an ongoing learning process rather than a specific center-based training. So, this entry will focus on continuous learning in corporate.

Learning Process at Corporate

The objective of the learning is to improve different skill sets like motor skills, verbal or communication skill, intellectual skills, cognitive skill (with challenges to thinking), and positive attitude to the task, as deemed necessary by the organization (Knowles et al. 2012). The focus might be on

two important components of learning: cognitive (that is recall of knowledge and development of intellectual abilities and skills) and affective (that is changes in interest, attitudes, and values and the development of appreciations and adequate adjustments) (Wood et al. 2018; Peleckis 2015; Russo and Benson 2005).

To ensure quality learning, evaluation should be there, which could be goal-based, process- or system-based, and outcome-based evaluation methods (Zinovieff and Rotem 2008). Goal-based evaluation is that to what extent the programs are meeting predetermined goals or objectives. Process-based evaluations identify how the performance improves interaction with stakeholders in delivering the program. Outcome-based evaluation is that how it improves the end result like satisfaction level of the stakeholders.

To maintain effective learning, organizations need to select a system according to the structure of the human resource and their availability to participate in the process. In most cases, corporate has adult workforce, so they would benefit following the principles of adult learning.

Adults have more life-experience than children and adolescents. That is why problem-based learning is more effective for adults, where learners are engaged in resolving the problem and the instructor acting as a facilitator. It is better that the training process recognizes the individual variation in learning and should tailor instruction according to participant's preference (Collins 2004). The adult learner prefers to be actively involved in learning and expecting the instructor acting as a facilitator. Problems in adult learning are prejudice, set habits irresponsive to change or resistive to new things, resistance to direction or command. Adult learners want freedom to choose, timely feedback to correct errors, to continue learning, and gain mastery of content and skills (Knowles et al. 2012). Workplace training with adult learners would therefore succeed if following actions are present: encouragement to create interest to learn or curiosity for the topic to learn, motivation on the reason and the process, justification based on past experience, relationship to current or future situation, autonomy or

self-paced learning, scope of experimenting or testing, and stress-free learning climate.

Self-directed learning with justification for the task is a better option for adult learning (Knowles et al. 2012; Collins 2004). Adult's motivation comes from comparative analysis that is a gain or benefit from current situation. Information on the impact of the learning on the work or to other responsibilities is valued by the adult learner. From that point, it is also beneficial to use the term "learning" rather than "training or coaching," as the adults might feel comfortable to improve their performance by themselves or gaining knowledge and expertise rather than feeling a teacher is directing them to do something in a classroom. The learning program needs to identify the learner's needs in consultation with the learners and learning activities be designed relevant to those needs.

Training program for adults needs to address the general principles like acceptability of content to the participants, goal oriented, relevancy oriented and practical, acknowledging the life experience and knowledge of the participant, scope of active participation, incentive to participate, immediately applicable to real-life contexts, climate of respect and comfort, and positive outcome in applying the learning (Lee et al. 2005).

Learning from an employee perspective needs consideration for any training program. As mentioned in the adult learning principles, learning depends on justification for it or need for it. In an insecure job market, employee will not consider spending much time on learning. Job security and potential for progression to higher position would improve learning. So, willingness of employee to engage in learning will depend on job security. Today, in most cases, employee does not want to learn but want help at the point of need.

In any learning process, it is also important to identify how frequently human resource be engaged in learning. The psychologist Hermann Ebbinghaus's memory retention curve could be a guide for organizations to arrange a schedule for training (Murre and Dros 2015; Custers 2010). The curve shows how quickly people forget after a learning session. After 10 min, 30% memory is

lost, and after 1 week, 90% is gone, in the absence of any refreshing or remembering activity. This brings the need for mobile devices to boost personalized learning process for the learner.

Assistance for talent development's (ATD) 2017 report (Ho 2017) mentioned that organizations' commitment to learning, the average number of formal learning hours used per employee is growing (grew from 33.5 h in 2015 to 34.1 h in 2016). These are stand-alone hours that are not embedded in work activities.

Traditional fixed center-based learning is weaning with the demand of accessing training at any point in the world at personal time preference. Traditional, instructor-led, face-to-face classroom-based training still contributes 49% of learning hours of the corporates, used in 2016. But the technology-based learning (E-learning) is rising (45% in 2016 compared to 41% in 2015). Both learners and instructional designers are upskilling in using technology, and also the user-friendliness, flexibility of the technology is improving. (Ho 2017)

The online learning management system started as an application to automate the administration, tracking, and reporting of training program in support of classroom education. It was intended to provide opportunity for self-service and self-guidance, rapid delivery of learning content at the users' preference, and personalize content with option for repeated access (Subramanian et al. 2014). Today, online learning is moving beyond any limit, not just supporting the classroom activity.

Online learning could be synchronous or asynchronous. Synchronous training is real-time training where trainer and trainee are online at the same time. In asynchronous training, entry (log-on) or exit (log-off) is personal preference both for trainer and trainee as the contents are in particular page and both have access to complete their task at their convenience.

The online training or E-learning system is described by several names, for example, computer-based training (CBT), computer-managed instruction (CMI), distributed online learning (DOL), learning management system (LMS), or learning virtual environment (LVE). Whatever

may it be called, these tools have three main user profiles: system administrators, teachers, and students (Guenaga et al. 2004).

E-learning provide an alternative way of learning comparing to traditional classroom learning for people with disability (Debevc et al. 2007). Web-based training (WBT) has helped removing the barrier of distance and making the presentation lively by high-dimension images and opportunity to magnify the image to allow the trainee a closer view of the object. Additional features can make the presentation more entertaining than even the face-to-face classroom experience. It has the opportunity to bring multiple examples in one presentation without even leaving the session. It has the scope to present a topic lively, but it would not be effective if the content and intent are obscured and instructional effectiveness is sacrificed (Lee et al. 2005).

Corporates develop a learning management system (LMS) or learning content management system (LCMS), depending on its structure, its operation, characteristics of the business, human resource, and competition in the industry locally or globally (Iglesias et al. 2014). The WBT encourages corporate to build their own storage system for resources and provide access to its members through certain medium. This is called internal repository that holds different learning content, presentations, or messages.

There are different tools for LMS in WBT program: WebCT, Blackboard, Macromedia e-Learning Suite or Docent Enterprise Suite, Moodle, ATutor, and Sakai. The last three (Moodle, ATutor, and Sakai) are open-source LCMSs (Iglesias et al. 2014).

Blackboard is well known across higher education sector and is a ready to use software. It charges per student or user rate. Moodle a free open source LMS is also appreciated in this sector but is not ready to use software, organizations need to customize it. Whether an organization will use the free LCMS (like Moodle) or paid system (like Blackboard) will depend on factors other than price, that includes: user number (some LCMS can handle more than 500 users', others cannot), ability to integrate with other platforms like Google apps, and smooth running of the

pages without being hanged. They have different functionality: one allows instructors to post course materials, readings, and assignments and allows basic discussion and the other one helps educators to manage the course by creating effective online learning communities to support self-learning (Subramanian et al. 2014). Products like “Internet of Things (IOT)” or “Internet of Everything (IoE)” are also integrating with the system (Dinc et al. 2019).

Supply of the Learning Material

Alternative to main frame computers started to emerge with the commercialization of personal computer in 1977, Apple II in 1978 and associated software (Myers 1998). Gradually, the appearance of discs, USBs, windows, and other mediums helped the expansion of the knowledge sharing beyond the classroom and initiated flexibility to learning. Corporates spend a lot to develop video, animation, and different means to help learning and to assess the participants. This opened the opportunity for WBT.

Availability of web-based training (WBT) is well embraced by corporates. WBT needed a browser, particular language (like HTML) to develop the content, and special program (like Flash) to display video or animation. It needed substantial fund to develop big voluminous content to complete a course. Learners needed fund to source computer with higher speed or storage capacity, subscription to the Internet and LMS.

Still then the level of satisfaction was limited, in value for money. Learners were not able to access it as and when needed. Technological glitch caused problem in accessing the content, hang-up in the middle of its run. It was difficult to get the desired content like searching a tiny fish in the ocean, not user friendly in finding the desired material, and needed the skill of using special jargon or technique. In the last two decades, with the expansion of broadband internet and fast-paced mobile communication devices in the developed countries, the E-learning speeded up.

Explosion of learning material started with the development of open educational resources

(OER) with UNESCO committee as the driving force (UNESCO 2002). The objective of that UNESCO initiative was to encourage open and free resources for all to use for teaching, learning, and research. Providers emerged with different types of repositories for OER (Merkel and Cohen 2015). Simple OER repositories (like Google or YouTube or Wikipedia or Face book) helps getting information that are easily uploaded by any registered provider no matter how much skilled they are on the topic. It serves mostly raw data, unverified and helpful for general knowledge on any issue. It is generated mostly by individuals, low cost production, easy to share by any citizen, provided governments do not interfere. It is good for sharing knowledge but not been well embraced by organization for educational purpose. Some OER repository are institutional repository for teaching with quality for authentication, accreditation, and acceptability in scientific community.

Current successful OER providers brought some added features to attract the learners. Service providers (like Google) improved its search engine with benefit to both general learners to institutional learners. Some OER (like Google, Wikipedia) are holding more than millions of articles in almost all languages of the world (Mesgari et al. 2015). But still matching the learners need is not easy. It is possible to narrow down the search by advanced users but not satisfactory at all time.

Emergence of mobile platform (like iPhone and Android phones) have advanced to bring some satisfaction to the learners by relatively easy upload and download facilities for their own video, provided the respective government agencies do not intervene. It is far easier to make an unedited video and upload or download as long as the carrier phone company has the network. This platform gave birth to a different style learning, i.e., learn from what others are doing and willing to share it with others. Instead of a trainer spending time in designing a course module, one worker or executive can send the video of what they can do and how, which others can accept or reject.

Dynamic organizations are using both OER and internal repositories to help learning, but the

conservatives are restrictive to internal repositories. Still use of internal repository is the main (around 90%) (Merkel and Cohen 2015). Instructional designers and training managers decide what resource to use from which repository. The use of OER in the corporate world might have some limitation if they are for-profit organization. Also use of OER (particularly YouTube and Google) is a common practice for all learners to gain a first-hand knowledge or preliminary information about the topic before entering into any internal repository.

The MOOC concept draws the attention of corporates to bring smoother large volume learning material delivery (Dodson et al. 2015). To facilitate on the job training, some corporates are building partnership with MOOC networking organizations and they predict employees will be required learning all the time (Gaskall 2017). They predict that learning and development will be forced to become an extracurricular activity rather than a core part of one's work. The year 2012 was "the year of MOOCs" as renowned universities joined with private companies to offer open and free, online education (Bogdan et al. 2017). But it is not a rosy picture for all learning program. There are failures or huge drop-outs in the MOOC operated free courses (Rivard 2013).

Around 2010, the LMS got support from a new technology to manage the digital content, mostly in integrating and organizing the contents. This brings following advantages: easy searching of content and faster retrieval of content (text or image or video stream). It is supported by artificial intelligence to generate role specific or interest specific or usage history specific content and notify (by text or email) to its members (who has signed in or subscribed).

National and international encouragements, like OER concept from UNESCO and digitalization policy from governments, have increased the supply of information and communication technology (ICT) to identify the need of employee learning. ICT products, like software HR Analytics, attempts to understand the cognitive aspect of human resource and to analyze data in the human resource department after

employment. It helps establishing relationship between human factors and its impact on the organization including performance and turnover rate (Angrave et al. 2016).

Competition ICT environment changes technology at a very fast rate (Xu et al. 2017). This gives advantage to the industry leaders and proactive leaders but makes life difficult for lagers or reactive leaders. It is now possible to source more personalized service to make the learning program more diversified and specific for each learner.

The effectiveness of E-learning technology in education sector would depend on several factors. Most important is the accuracy or authenticity and fulfilling the standard of the education regulatory authority. Accessibility of users is always a factor particularly for the low socioeconomic group, also the willingness of the corporate or governments to share information need consideration.

As with previous technology adoption in learning environment, it is time dependent, aggressiveness of the corporates to use it in the system, encouraging factors to engage learners or employees in the system. The class-based learning and this LMS learning differ in stimulating factor. In class-based learning, teacher or trainer stimulates to learn or the presence of the trainer engages learners in different activities to learn (may be little bit or more). In LMS, learner's maturity or focus on the issue is the important factor to stimulate learning. Usually people learn when a perceived need is present (Beer and Schrader 2016a; Knowles et al. 2012). With the new technology, if learners or organizations do not change their attitude, then it will not be effective.

Challenges in e-Learning at Corporate

Common problem with WBT is that the learning designers consider only the presenting ability of the technology but fail to identify the justification of the content for the learner or organization and also to identify the difficulties related to navigation process for the learners. Any learning program needs to have effective design of learning content, appropriate user interface design, and appropriate evaluation process (Lee et al. 2005).

Corporates spend on training, but in many cases, the return on investment (ROI) does not match with gain, in terms of changes in individual behavior or organizational culture or even financial performance (Beer et al. 2016a). In some cases, change is very short lived, and people revert to old ways of doing things, initial performance spike drops to base. This might relate to conflicting priorities on strategy and values, senior executives' behavior does not reflect the desired change, poor organizational design hinders honest conversation on problems, inadequate time and attention to talents or critical issues, and fear of backlash for criticism or telling facts. Effective remedial measures include: review of the learning process at regular interval, consider alternatives to current learning and development process, analyze the context for relevancy, and fix design and management process (Beer et al. 2016a).

Web accessibility depends not only on accessible content but also on accessible Web browsers and other user agents.

With inclusion of online learning system as an integral part of training in many countries, the trainers would need to be well conversant with Web Content Accessibility Guidelines (WCAG) and WCAG 2.0 AA standards. This WCAG guideline intends to make web contents accessible to people with disabilities, to older individuals with changing abilities due to aging and even to improve usability for users in general. The World Wide Web Consortium develops WCAG standards and measures the accessibility of the websites by those people (Caldwell et al. 2008). Organizations need to assess and monitor the LCMS to guarantee universal accessibility to ensure participation of all learners (Iglesias et al. 2014).

In light with the WCAG guidelines, it is now a challenge for organizations to improve the accessibility option, so that people with disability or with other limitations can participate in the learning process without too much additional work (Guenaga et al. 2004). The WCAG standard encourages course content developers, instructional designers, ICT professionals, and all other entities involved in the E-learning creation and delivery process to consider alternative tools, platforms, methodologies, and services.

Even though there is optimism in using E-learning system, currently available tools have accessibility barriers that make the creation of accessible E-learning environments difficult for learners and organizations (Calvo et al. 2014).

There is difficulty in utilizing the tools due to misconception using it or proper understanding of the system. While including this ICT in the training program, sometimes organization fails to understand that the people are the center of the system (Dinc et al. 2019).

There are challenges like the Internet or online connectivity, security, right hardware and software, etc. The IOT's are today part of infrastructures in many services. An app in the ICT is great as long as its cyber-physical aspect is known to the user or the creator of the system and proper measures taken to ensure security. It is required to have a "smart cyber-physical system" in the Internet of things to avoid harm in hostile environment like cyberwar (Izosimov and Törnngren 2019).

A system could be safely used as long as the password is kept contained within the secure circle and leak to opportunist people could cause harm or loss.

There is a concern that corporates are failing to identify the learner's interest or need (Anton and Shikov 2018). In traditional classroom training, teacher-student interaction allowed the quick identification of the learner's discomfort or weakness in gaining knowledge. In E-learning, absence of that interaction challenges the training organizers with the task to develop proper assessment task to accurately reflect the learner's knowledge gain and ability to reflect in workplace.

To gain from the learning process, corporates need tools to evaluate the appropriateness of the design of the training and identifying the effectiveness of the process to reflect the organizational perspective (Lee et al. 2005).

Introduction

One need not be an expert in information and communications technology (ICT) to realize the ever-increasing influence on and omnipresence of ICT applications in the society. It is therefore easily assumed that everyone possesses basic ICT skills and can use simple ICT applications. Especially university students, who are considered to be “digital natives” and who have had ample exposure to a variety of ICT applications and training, are often thought to be a homogeneous group with near-perfect basic ICT skills and highly frequent ICT use. This, however, is contradicted by research, and the current paper aims to provide some answers to the question why university students differ in their basic ICT skills and use.

Like in the social sciences at large, different data collection methods are available to study ICT skills and use (Nair and Das 2011). While direct

observation (e.g., Madigan et al. 2007) can yield high-quality data, it is often expensive and not practical for large samples. Survey questionnaires that collect self-reports of behavior are easier to use in large samples, but may not be fully reflective of the actual behavior or interest. While some have used mixed approaches (e.g., Hohlfeld et al. 2013), most research relies on self-reported data (Nair and Das 2011), as does this one.

While looking for predictors of ICT skills and use, some researchers kept it simple and limited the observation to variables that have quite often shown differences in social behavior, for instance, gender, age, education level, and status (Hargittai 2010; Salajan et al. 2010; Goldhammer et al. 2016; Mansur and Cakmak 2016).

Although these variables can be very useful to detect differences in the society, they leave a lot to be explained. Different theories are available to explain proficiency in ICT skills and frequency of ICT use. The *Technology Acceptance Model* (TAM) has been particularly influential. It was proposed by Davis (1989) in the context of the acceptance of computers. Davis constructed two explanatory indices: (1) the perceived usefulness of technology (will the use of this technology enhance my work?) and (2) the perceived ease of use of a technology (will it be easy to apply this technique?). In 2003, Venkatesh published an article in collaboration with Davis and others in which TAM was integrated into what was called the *Unified Theory of Acceptance and Use of Technology* (UTAUT) (Venkatesh et al. 2003). This theory included the two variables proposed by Davis and added social influence and facilitating conditions to the model. Social influence refers to the perception of an actor that an influential other believes that he should choose for the new technology. Facilitating conditions are expressed in the belief of an actor that there is an organizational and technical infrastructure supporting the use of the technology. Besides these four variables, three additional variables were introduced as indirect determinants mediated by perceived ease of use: self-efficacy, anxiety, and attitude. Self-efficacy is defined as the

degree to which an actor believes that he can do a job without the assistance of another actor. Anxiety refers to concerns in using a new technology. Attitude encloses the affective reaction of an actor toward the new technology. Besides this, Venkatesh et al. (2003) contend that also the usual variables such as gender, age, and experience may aid in predicting the use of new technology.

The success and limitations of the TAM have been documented by Marangunić and Granić (2015), for mobile learning by Al-Emran et al. (2018), and for UTAUT by Williams et al. (2015).

In this entry another path is followed. Former studies (for instance, Papanastasiou et al. 2005; McMahon 2009) have shown that at least ICT use might be positively related with achievement in science subjects and improved critical thinking among young students, but have not investigated this link at the level of university education. Accepting that the study of science familiarizes students with the procedures of scientific research, one can hypothesize that students interested in scientific research will also be interested in ICT. In this current research, based on theoretical considerations presented in the next section, it is expected to find an association between the level of ICT skills and use and the degree to which university students are research-oriented. As explained in the “[Methodology](#)” section, on the basis of a questionnaire filled out by bachelor’s students, the association between ICT use and skills and research orientation, taking into account the ICT learning experiences of the students and some important contextual variables is investigated. Section “[Short Overview of the Main Variables](#)” presents a short overview of students’ access to PCs and the Internet, their learning experiences, and their attitudes toward scientific research. In sections “[Learning Experience and Identity Commitment as Predictors for ICT Skills](#)”, and “[Learning Experience and Identity Commitment as Predictors for the Frequency of ICT Use](#),” both the learning experience model and the identity commitment model are tested as predictors of, respectively, ICT skills and the

frequency of ICT use. In the final section, some conclusions are drawn.

Theory

The Role of Experiential Learning

Learning is not limited to formal learning organizations such as schools, but takes place in all kinds of situations where people meet each other (Cox 2013). From a very young age, children experience pleasure when they can do what others do. They feel they belong to a group because they can act like the other group members, whether family members or playmates (Dewey 1933: 206, 257). Unmistakably, John Dewey (1933: 258; 1938: 236; Kolb and Kolb 2005) stressed the power of experience in this learning process. He emphasized the advantage of belonging to a group where the objective of learning is highly appreciated (Dewey 1933: 38; 1938: 25), and he underlined the capacity of this to stimulate the motivation to learn more about what people need in order to function in a group. These opinions are shared by other researchers. Jeffrey et al. (2011) refer to several other researchers in stressing the importance of the personal relevance of the learning content for a successful learning process. This also partly explains success in learning ICT. Although in many countries ICT is formally taught in schools, an important part of ICT knowledge is gained at home or among friends. In Western societies, ICT is widespread and computers and the Internet have a place in many families. Parents and siblings play an important role in making this technology accepted (Vekiri 2010; Zhao et al. 2010). Children discover how much fun it is to play games on the computer and, more importantly, feel that learning how to work with ICT instruments is also highly appreciated by parents and siblings.

Vekiri and Chronaki (2008; Vekiri 2010) mention research where the link between the socioeconomic position of the parents of the students and ICT use is supported in elementary schools and in secondary and higher education. However, using regression analysis, they

concluded that home computer access, frequency of use, variety of activity, and perceived parental and peer support were not or were just marginally related to students' self-efficacy and value beliefs. Similar critical observations were made by Verhoeven et al. (2010) and De Wit et al. (2012). In a regression model where in addition to social background (the socioeconomic position and education level of the parents of the students), the variables of usefulness and control of the computer, computer anxiety, and Internet competences were included in explaining the frequency of use of computers for study, chatting, and games by secondary school students, no substantial relationship was found with social background. The only relationship found was a lower frequency of computer use for recreation by working-class students compared with other students. The same phenomenon was observed by these authors among university freshmen. The socioeconomic position of the students in combination with other variables showed a minor influence on the ICT skills and the frequency of ICT use of university freshmen. This indicates that influences experienced at a very young age do not always have apparent consequences in secondary school and at university. Moreover, De Wit et al. (2012) also found that the effect of influence might change over the years. For example, they found that in 2005, students whose father or mother had completed higher education were less capable of installing a computer than other students were, but that this relationship was the opposite in 2009. In addition, in 2005 students whose father had completed higher education chatted more online than other students, and those whose mother had completed higher education chatted less. In 2009 both relationships were reversed. In other words, situational developments might change previous relationships.

Peers also play a role in learning about ICT and the Internet. Students mention friends as the second most important source of ICT knowledge (mean score = 3.29 on a scale of 1 to 5) (Verhoeven et al. 2010). Nevertheless, students overwhelmingly consider themselves as the most important instructors of ICT for themselves (mean

score = 4.02), thereby offering a good example of what J. Dewey would call agents, not simple receptors (Dewey 1917; Evans 2000).

This leads to the hypothesis that students whose families, peers, and teachers more intensely support contact with and instruction about ICT will possess more developed ICT skills and will use ICT more often than students who did not grow up in such an ICT-oriented environment. Nevertheless, based on relevant literature, this relationship is not expected to be very strong.

The Role of Students' Identity Commitment

Earlier research has indicated that the vocational orientation of university students significantly influences the use of ICT and the command of ICT skills (Verhoeven et al. 2010; De Wit et al. 2012). Vocational orientation could be called a form of commitment, as defined by Burke and Reitzes (1991) in the following way: "(it) refers to the sum of the forces, pressures, or drives that influence people to maintain congruity between their identity setting and the input of reflected appraisals from the social setting." The identity setting of a university student is, among other things, composed of a belief in his or her academic competence, a vocational orientation (studying for a particular profession), and an orientation toward becoming a scientific researcher or another professional. Interactions with others may support or blur this identity and can influence a student to pursue or abandon these intentions. If the identity commitment is strong, a student will adhere to the expectations of the group that link him or her to a particular identity setting. A student who benefits significantly from living close to this student setting will very probably be more committed to that identity than other students. Burke and Reitzes (1991) discerned two bases of commitment. First, cognitive bases refer to positive rewards coming from interacting with people as a result of maintaining the expected identity. Assuming that a student has an elementary knowledge of ICT, stimulating the appraisal of other students might motivate a student to work harder toward mastering ICT skills. Second, socio-emotional bases refer to ties between people who share

the same position and experience the recognition of others as supportive confirmation of the adequacy of their behavior. When a student experiences the acceptance of other students, he or she will most likely try to maintain interactions with these positive, rewarding colleagues.

A stronger commitment to a professional career in research or in another area, and a belief that ICT will be a necessary or inevitable component of a future career, might lead students to have a stronger commitment to using ICT and using it more frequently. Moreover, using ICT involves taking a number of steps that are also part of carrying out scientific research. This similarity might add (albeit not at a conscious level) to a stronger link between training in scientific research as a part of an identity setting and knowledge of ICT skills and the use of ICT.

Scientific research has characteristics similar to that of an information system, which Zwass (2019) defined as "an integrated set of components for collecting, storing, and processing data and for delivering information, knowledge, and digital products." Scientific research starts with the question of why a particular phenomenon is what it is or why it functions in the way that it does. Researchers start with some hypothetical explanations and collect data to test whether a hypothesis can be rejected or not. Observations, methodologies, and interpretations are stored, because there should always be an opportunity to check and recheck the research data and results. It is also important to have an instrument to rapidly retrieve any data that researchers might be interested in. The process of scientific research does not stop there. Results should be made available to colleagues and a wider audience; they should be publically displayed. Research is also expected to be useful. This all takes place in collaboration and in discussion with the wider scientific community. Researchers collaborate locally but also internationally. Datasets are transmitted from one continent to another, discussed by researchers who live far away from each other, but jointly publish in journals that are read throughout the world. They meet at international seminars and conferences, teach each other's

students, engage in common projects, etc. In other words, scientific research shares many characteristics of information systems as described by O'Brien and Marakas (2009: 4): "An information system can be any organized combination of people, hardware, software, communications networks, data resources, and policies and procedures that stores, retrieves, transforms, and disseminates information in an organization." Each information system comprises some basic activities. In order to obtain information that has to be processed, a worker needs instruments to capture this information (for instance, a keyboard or a scanner). This captured information has to be transmitted or processed to another device (for instance, another PC in a network) in order to work with it later. Therefore, it must be stored (for instance, on a hard disk or a USB stick). When needed in a later process, this information needs to be retrieved. This procedure takes the results of the storage process and uses them to elaborate the information. The old information (output information products) is used to create new information, to reorganize the information, and to recalculate what has been retrieved or for similar operations. At the end of this process, the results are shown to an observer who might be interested in the results of analyzing the information. At the end of the input, processing, output, and storage, a control of the system performance should be established.

This brings us to the hypothesis that students who are interested in scientific research and/or want to become researchers will be more open to mastering ICT skills and/or will make greater use of computers and the Internet for their studies than other students will. Indeed, ICT offers them useful instruments for attaining the targets that researchers have in mind and helps them to be rewarded for showing a commitment to their identity setting.

Methodology

Data for this project were gathered through an online questionnaire filled out by bachelor's students at the University of Leuven (KU Leuven),

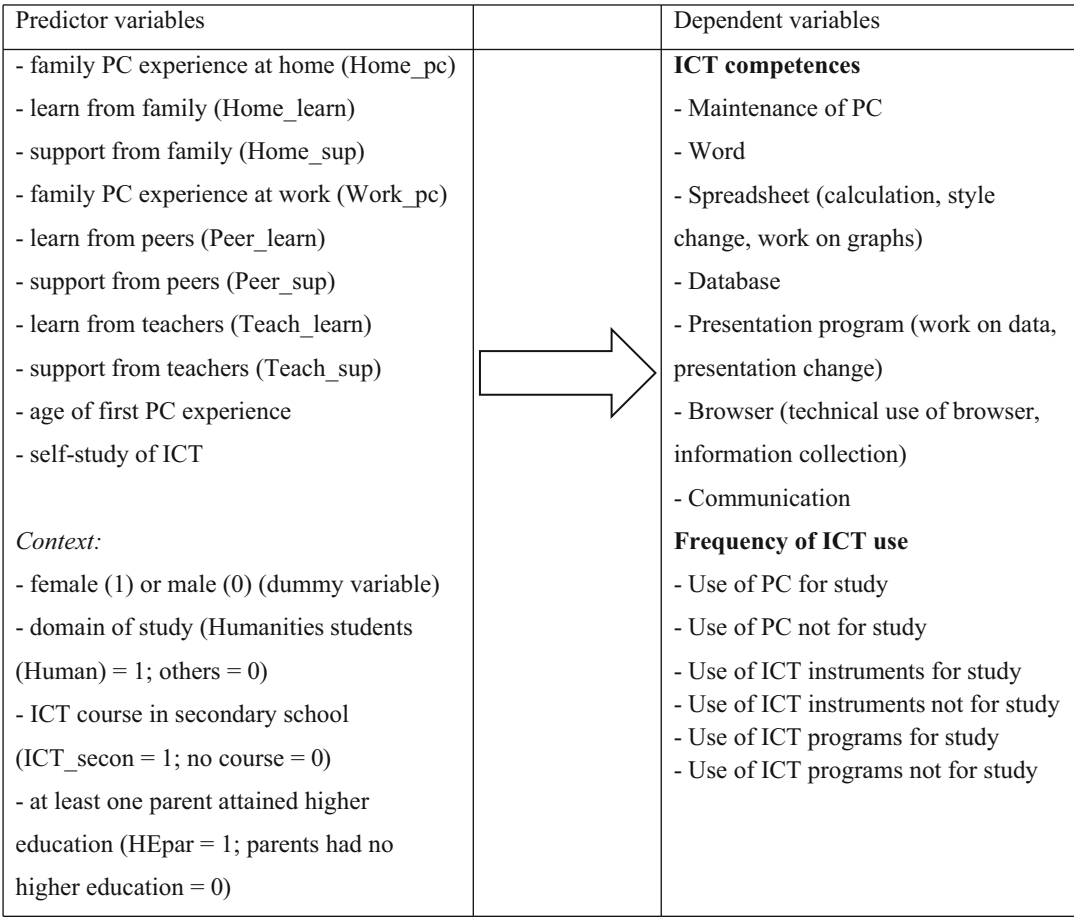

which is one of the largest Belgian universities. It is a comprehensive university with a wide range of scientific disciplines and domains of study. Although the university buildings are spread across the town, the university has a well-developed intranet system offering broadband Internet access to all students, even those in privately rented accommodation. In 2012, the university was attended by 40,257 students, among whom 45% were studying at bachelor's level and 31% at master's level and 11% were PhD students. In this project, research is focused on bachelor's students who had passed their first-year exams and would not take their final bachelor's exam in 2013. This is a population comprising 3,609 students. Most of them had been at the university for at least a year and were supposed to be familiar with the ICT equipment of the university and the expectations of the staff concerning ICT use in and outside classes. In total, 1,232 students answered an online questionnaire between 13 November 2012 and 18 December 2012. Students received up to two e-mail reminders after an initial e-mail invitation to participate in the survey. The analysis used here involves 1,180 students who responded to at least 75% of the questions and fell within the age range of up to 25. Because the multivariate sample distribution for gender, age, and faculty deviated to some extent from the population distribution, a weighting factor was calculated by iterative proportional fitting.

These hypotheses are tested using two models (see Figs. 1 and 2). The first model focuses on the learning experience of the students, and the second on their identity commitment. Both models are expected to contribute to the prediction of self-perceived ICT skills and self-reported frequency of ICT use.

Dependent Variables

ICT Competences

The seven ICT competences in Figs. 1 and 2 are measured using scales consisting of several items. These scales have been used in previous research and have been refined over the years to capture new types of ICT use (e.g., inclusion of references

Predicting ICT Skills and ICT Use of University Students, Fig. 1 Explanatory model 1: learning experience (Verhoeven et al. 2016, p. 78)

P

to social networking sites [SNS]; cf. Verhoeven et al. 2010; De Wit et al. 2012).

Based on a review of several instruments, in particular ECDL Syllabus 5.0 (ECDL 2010), new items were developed. A paper questionnaire containing the existing and new items (a total of 123 items) was tested in a nonrandom sample of 85 university students. The response format for all items was identical (a five-point Likert-type rating scale ranging from “totally not true for me” to “totally true for me” with the midpoint “more or less true for me”).

The resulting data were analyzed using exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) in Mplus version 4.0. The EFA was used to identify appropriate items, and the

CFA was conducted primarily to assess goodness of fit. The selection of the final items was based on the results of the factor analyses and an evaluation of the distribution of the individual items (items with strong ceiling or floor effects were deleted). In total, 49 items were included in the final questionnaire. The items were distributed over the seven ICT skill domains as follows: 7 for maintenance of the PC, 6 for word processing, 14 for spreadsheets, 6 for databases, 6 for presentation software, 7 for browsers, and 3 for communication. All items of the scales are published in Heerwegh et al. (2016). The data obtained from the main survey (1,180 students) were subjected to confirmatory factor analysis (CFA) in Mplus version 4.0.

Predictor variables		Dependent variables
- academic self-perception (Acadsc) - vocational or professional orientation (Profor) - attitude toward science (Attit_science) - intention to become a researcher (Intent_sc) - intention to become something other than a researcher (Intent_oth) - Scientific research needs ICT (ICT_science) <i>Context:</i> - female (1) or male (0) (dummy variable) - domain of study (Humanities students (Human) = 1; others = 0) - ICT course in secondary school (ICT_secon = 1; no course = 0) - at least one parent attained higher education (HEpar = 1; parents had no higher education = 0)		ICT competences - Maintenance of PC - Word - Spreadsheet (calculation, style change, work on graphs) - Database - Presentation program (work on data, presentation change) - Browser (technical use of browser, information collection) - Communication Frequency of ICT use - Use of PC for study - Use of PC not for study - Use of ICT instruments for study - Use of ICT instruments not for study - Use of ICT programs for study - Use of ICT programs not for study

Predicting ICT Skills and ICT Use of University Students, Fig. 2 Explanatory model 2: identity commitment (Verhoeven et al. 2016, p. 79)

Frequency of ICT Use

The frequency with which students use a computer, ICT instruments (hardware), and ICT programs (software) was measured separately for study purposes and for all other purposes. Students were asked how frequently they engaged in specific behavior (surfing the Internet, e-mailing, chatting, goal-oriented online searching, downloading movies or music, participating in newsgroups, writing blogs or wikis, and playing games – the last item was not asked when gauging ICT use for study purposes), how often they used ICT hardware (use of a PC or laptop, Internet, mobile, iPad or tablet, iPod, iPhone

or smartphone, digital camera, and e-reader), and how often they used specific software (word processing, spreadsheets, databases, SNS, Twitter, virtual learning environments, drawing software, statistical programs, qualitative data analysis programs, and specialized software). The response options were daily (score = 6), four to five times a week (score = 5), two or three times a week (score = 4), weekly (score = 3), monthly (score = 2), less than once a month (score = 1), and never (score = 0).

An average score was calculated across all items of each of the three variables separately for study and for non-study purposes (use of a

computer, use of ICT instruments, and use of ICT programs), for use in further analyses.

Independent Variables

Learning Experiences

Learning experience of ICT was measured using several indicators. The survey questionnaire included items on whether the student's father, mother, or siblings used a computer at home (Home_pc; score range = 0–3) and at work (Work_pc; score range = 0–3). Both situations might create a positive attitude toward using computers.

Three questions referred to how much students had learned about ICT from family members (father, mother, and siblings), peers, and teachers. The response options were “I did not learn anything from (e.g., my father)”; “I have learned a little, much, very much from (e.g., my father)”; and “not applicable.” All answers about the degree of learning from family members (Home_learn) were averaged to obtain a scale that ranged from 1 (learned nothing) to 4 (learned very much). An identical procedure was followed for learning from peers (Peer_learn) and from teachers (Teach_learn).

Three additional questions collected information about who might be able to provide support while working with ICT. Students were asked how often they could request help if they experienced problems with a computer or the Internet. A distinction was made between support from family (Home_sup), peers (Peer_sup), and teachers (Teach_sup), and the same response options were provided: never, seldom, mostly, always, and not applicable. The average scores were calculated for each source of support, with the scale ranging from 1 (no support at all) to 4 (maximum support).

Dewey's learning theory also points to the relevance of the learning content for a learner. If something is highly relevant for a learner, he or she will stress this by engaging in learning activities. To obtain a measurement of this, the survey asked how much respondents had learned about computers and the Internet by themselves

(score range = 1–4) and their age when they had first started using a computer.

Identity Commitment

Identity commitment is composed of four indicators. First, academic self-perception or academic self-concept (Acadsc) was measured with seven items such as “I rate myself highly in terms of my academic ability as an undergraduate,” “I have great self-confidence in my ability to succeed academically at the university,” etc. (based on Bennett 2009). The same response options as for the indicators for ICT skills were provided.

Second, a Likert scale to measure the extent to which a student is “vocation directed” was used (Profor) (Vermunt 1994). It contains five items such as “What I want to acquire above all through my studies is a professional skill,” “the main goal I pursue in my studies is to prepare myself for a profession,” etc. and could be answered with the same response options as the academic self-perception scale.

A CFA was conducted on the items intended to measure academic self-perception and being vocation directed.

Third, to measure the attitude toward scientific research, a Likert scale was developed with 12 items, such as “Scientific research is fun,” “I would enjoy school more if they did not bother us with scientific research,” etc. A scale used by Cheung (2009) concerning the appraisal of chemistry by secondary school students, was followed, but the items were adapted for the appraisal of scientific research (attit_science) (see Fig. 2).

Fourth, 13 survey items were included that gauged the students' intentions regarding their later professional life. Example items include “In my professional life I want to conduct scientific research,” “In my professional life I want to teach,” and “In my professional life I would prefer to work with people.” Factor analysis showed two scales: one refers to the intention of a student to become a researcher and the second to the intention to pursue a career other than research.

The hypothesis was that students who are more research-oriented will also have a higher level of ICT skills and use ICT more often than

other students. It was considered that this relationship might not be equally strong for all study disciplines, and therefore items to measure the extent to which students themselves are convinced that ICT is necessary for a scientific researcher were included. This information was collected with nine items such as “Today a scientific researcher cannot work properly without a computer,” “A scientific researcher should be capable of working properly with database software,” etc. (ICT_science). Factor analysis has revealed that these nine items form a good scale.

Contextual Variables

Research has shown that there are still factors that might create inequality of opportunities for some categories of the population (see section “[Introduction](#)”). Former research indicates the importance of gender, domain of study, taking an ICT course in secondary school, attending classes at university where a computer is used, and the education level of parents for the development of ICT skills and the frequency of ICT use by students (Verhoeven et al. 2010; De Wit et al. 2012).

Gender is included as dummy variable (female = 1, male = 0). With regard to the domain of study, it was expected that science and biomedical students (score = 0 for the dummy ‘Human’) will be more skilled in and more engaged in ICT activities than humanities students (score = 1 for the dummy Human). Having attended classes dedicated to ICT in secondary school and at university might also stimulate students’ ICT skills and frequency of ICT use. Two dummy variables (one for secondary school and one for university) are included in the models (0 = did not attend at least one ICT class, 1 = did attend at least one ICT class). At the university, this dummy refers to attending classes where a computer is used by the students.

Like many other opportunities in life, living in a well-to-do family creates more opportunities for easy and comprehensive access to ICT at home. Belonging to a particular social class creates or diminishes opportunities. While it is recognized that social class is a complex concept, the education level of the parents was chosen as a crude

indicator of social class. Students with at least one parent with a college or university degree were coded 1 on the dummy variable HEpar, while 0 refers to other students.

In the next sections, regression analyses are used to test the hypotheses.

Short Overview of the Main Variables

Before examining the results of the analyses, this section presents a short overview of the access of students to computers and the Internet, their learning experiences, and their attitudes toward scientific research.

A computer is a basic equipment for a student today: of the students surveyed, 99.5% of those living in rented accommodation and 99.7% of those living at home use a computer. Of the latter, 27% share this computer with another person, whereas among students living in rented rooms, only one student does. Of the computers that are at the disposal of the students most of the time, about 88% are laptops, 7% are desktops, 3% notebooks, and the rest netbooks or tablets. All the students, except one, have access to the Internet in their room and/or at home. Some 82% of the students living in rented accommodation have broadband Internet access both at home and in their rented accommodation, whereas the students living at home always have a broadband connection at home. It should also be noted that the student without a connection in his room or at home can use the Internet, as the university provides many places where students have free access to PCs and the Internet and all students receive an e-mail address from the university.

Knowing that 85% of the students have at least one parent with a higher education diploma, it can be expected that use of a computer and the Internet is self-evident for most of these families (see Fig. 3a). The use of a PC at home by parents and siblings gets an average score of 2.67 out of 3, and 89% of the parents of these students and 90% of their siblings use a computer at home. Some 77% of the fathers and 63% of the mothers of the students also utilize a PC at work (score 1.72 out of 3). This shows that the use of a PC belongs

Predicting ICT Skills and ICT Use of University Students, Fig. 3 (a, b) Average score of ICT learning experience scales (Verhoeven et al. 2016, p. 86)

to the daily life of most of these students and their families. Many of them started using a PC at a young age: the average age is 11.91 (std dev = 2.46); a quarter of them were 10 or younger.

Nevertheless, this does not mean that students believe they learned most about computers and the Internet from family members. They believe

that this knowledge is mainly the result of self-study. They consider the second most important informant about ICT is their peers and the third their teachers and their family. When students need support for solving PC or Internet problems, they first ask their peers, second their parents and/or siblings, and third all types of teachers in secondary school and at the university.

Predicting ICT Skills and ICT Use of University Students, Fig. 4 Average score of academic and scientific research orientation scales (Verhoeven et al. 2016, p. 86)

Most students attended an ICT course in secondary school – only 15% did not. At the university, some classes focus on special computer programs, but not on the basics of ICT. During the semester when the interviews were conducted, 53% of students attended one or more classes where students work on a PC. For 50% of these students, this happened weekly, for 20% several times a week, and for 30% monthly.

Scientific research is a positive factor, though a score of 3.27 out of 5 is not very high (see Fig. 4). To become a scientific researcher is not a priority for many students (score 2.56 out of 5). This might be the result of the knowledge among students that in order to become a researcher at the university a candidate should achieve higher than average. Moreover, at this stage of their education, students do not always have a clear picture of what a researcher is supposed to do. They are more interested in becoming a consultant, a teacher, a manager, or something else than a scientific researcher (score 3.17 out of 5). Nevertheless, most students are convinced that a scientific researcher cannot function properly without sufficient knowledge of the basic ICT skills (score 4.02 out of 5).

Learning Experience and Identity Commitment as Predictors for ICT Skills

It would seem safe to suppose that (at least some) ICT skills are widespread among students. After all, PCs are present in primary and secondary schools, and most students have already had to carry out tasks using a computer and the Internet at home. Writing papers, searching the Internet for a purpose, and making presentations are the daily practice in secondary schools.

Therefore, it is expected that most students at university would be convinced that they could work with a word processor, search the Internet, and make a presentation. Figure 5 confirms this expectation. It is clear that most students know how to work with a word processor (score 4.66 out of 5) and are convinced that they can do a search on the Internet (4.6 out of 5). A large proportion of the students are certain that they can maintain a computer (score 4.24 out of 5), change the style of presentations (score 4.16 out of 5), or work on the data of a presentation (score 4.12 out of 5). However, they feel they are less capable of making use of the technicalities of a browser (score 3.89 out of 5) or working with

Predicting ICT Skills and ICT Use of University Students, Fig. 5 Average scores of ICT skills (Verhoeven et al. 2016, p. 84)

digital spreadsheets. With regard to the latter, they believe that they are better at making calculations (score 3.91 out of 5) or working on graphs (score 3.89 out of 5) than making style changes (score 3.68 out of 5) in spreadsheets. In comparison with the former skills, most students are less familiar with the more special types of communication (score 2.93 out of 5). It should be stressed that communication skills are not about chatting or participating in SNS, because only 4% of the students did not chat on the Internet this academic year and only 8% did not use a SNS. The students are the least familiar with databases. Most students have only some vague knowledge of this subject, and 25% of them do not know anything at all about it.

Can learning experience and identity commitment explain some of the knowledge level of these eleven ICT skills? Neither model is very strong, but both show many significant predictors for ICT skills. Learning experience can explain 29% of the variance in the computer maintenance skills of students and 25% of the variance in the skills to use the technicalities of a browser. However, learning experience explains only 19% or less of the variance in all other ICT

skills, with the contribution being the weakest for word processing skills (6.2%) and the two skills linked with presentation programs (5.4% and 5.6%). These skills are widespread among the students (see Fig. 5).

Of the ten independent variables that are directly linked with the learning experience of the students, two contribute significantly to the explanation for all ICT skills. The strongest of the two is self-study, followed by age at the first experience of using a computer. The general pattern is that students who score high for self-study also score high for all ICT skills. However, the age when students first used a computer had negligible effects (although statistically very significant) on their ICT skills. The other forms of learning experience help little in better predicting ICT skills, except for the skills to use a spreadsheet, a browser, and a database. The more students have learned from their teachers, the higher they score for spreadsheet and database skills, although self-study is here also deemed more important than information from teachers. Some relationships are hard to understand. First, the more students have learned from their peers, the less they score on changing styles and working on graphs in

spreadsheets. Second, the more support students receive at home, the lower they score for the skills to work with a browser. These negative relationships need more research to understand why they develop in this way.

Contextual variables also play an important role. Except for word processing, female students score lower than male students for all ICT skills, a phenomenon that is often observed. Students who participated in an ICT course in secondary school score higher than other students for 9 of the 11 ICT skills. Humanities students score significantly lower on spreadsheet skills and word processing skills than science students do. Why students in the field of humanities score higher than science students for database skills is not immediately clear. This is also true for the relationship between higher education level of one of the parents and knowledge of ICT skills. Contrary to the expectation, students whose parents took higher education do not score higher for ICT skills. Additional research will be needed in order to explain this unexpected finding.

The second model, identity commitment, is weaker than the first. Nevertheless, it does unveil some interesting predictors for ICT skills. Some 20.3% of the variance in the technical use of a browser can be explained by this model, as can 17.6% of the variance in the maintenance skills of students. The model also explains between 16.3% and 15.1% of spreadsheet skills. Less variance is explained for the other skills (between 10.1% and 3.2%).

Regression analysis shows that the more students believe that a scientific researcher needs a good knowledge of ICT skills, the more they know about the different ICT skills. This is also true for students who place a high value on scientific research, but not for all ICT skills, notably style changes in and calculation skills with spreadsheets and working with databases. Contrary to the expectations, the intention to become a researcher only positively predicts competence with style changes in spreadsheets, and the intention to become something other than a researcher

only predicts the ability to work on data in a presentation program and in communications. The predictive power of these variables is below the expectations.

A positive academic self-perception and a high vocational orientation were expected to contribute to a better knowledge of ICT skills, because ICT might be helpful for study and research. This is shown to be only partly true. The higher the academic self-perception of students, the better knowledge they have of the skills to work with a word processor, to do calculations or work on graphs in spreadsheets, and to collect information with the help of a browser. When students are more vocationally orientated, they think they are more capable of making style changes in spreadsheets or working with databases or with presentation programs.

Again, similar to the first model, contextual variables provide important predictors for the ICT skills of students. Gender is the strongest predictor of all the variables in this model, except for word processing. Female students are less acquainted with ICT skills than male students. Students who attended an ICT course in secondary school score higher for ICT skills (except for information collection and communication) than other students. Humanities students seem to know less about working with spreadsheets or a word processor than science students, but have a better understanding of databases. For other ICT skills, there is no difference between the two groups.

Students whose parents did not graduate in higher education believe they have a better knowledge of how to handle some of the technical aspects of a browser than other students do, but this is the only skill where a difference between these two groups can be found. The ICT head start that students of the more privileged families might have had does not show at the university. In addition, no differences are found with regard to the knowledge of ICT skills for students who did or did not attend an ICT course at the university during the semester when the survey was conducted.

Learning Experience and Identity Commitment as Predictors for the Frequency of ICT Use

Turning to the frequency of ICT use instead of ICT skills, both models were tested again as predictors. Figure 6 reveals that computers are more frequently used for purposes other than study (score 2.91 out of 6) than for study (score 2.61 out of 6). This is also true with regard to the use of ICT instruments (respectively, scores of 3.05 and 2.05). However, students do use ICT presentation programs more frequently for study (score 1.7 out of 6) than for non-study purposes (score 1.34 out of 6).

Figures 7 and 8 show in more detail that the majority of students uses computers daily, but mainly for non-study purposes. More than four fifths of the students surf the Internet daily for fun, and about three quarters send e-mails to friends daily. Chatting is also popular: six tenths do this daily for fun. These figures are much lower when they are in connection with study: respectively, 54%, 51%, and 29%. Other activities, such as downloading music or films, participating in newsgroups, writing blogs or wikis, and

playing games, are less popular, even when they are not related to study purposes.

A similar varied picture is found for the frequency of use of ICT instruments and programs (not shown in the figures). For instance, computers and the Internet are used daily by 93% of the students, but an e-reader was never used by 92% of the students during this academic year, and an iPad or tablet by only 76%. Most students used the local virtual learning environment (98%), a word processor (95%), SNS (86%), or a presentation program (81%) in this academic year for study; the figures for non-study purposes are, respectively, 22%, 81%, 82%, and 34%.

Given this varied picture of the frequency of use of computers, ICT instruments, and ICT programs, the question is whether the two models can help to predict the variation. The learning experience model does not explain a large proportion of the variance of the frequency of use, but as was the case with ICT skills, it provides some significant variables that allow a better prediction of the dependent variable, namely, PC use for non-study purposes (17.5%) and the use of ICT programs for study (11.5%). For all other dependent variables, the proportion of explained variance is 6.3% or lower.

Predicting ICT Skills and ICT Use of University Students, Fig. 6 Average frequency of ICT use by bachelor's students (Verhoeven et al. 2016, p. 85)

Predicting ICT Skills and ICT Use of University Students, Fig. 7 Frequency of computer use for study (Verhoeven et al. 2016, p. 91)

Predicting ICT Skills and ICT Use of University Students, Fig. 8 Frequency of computer use not for study (Verhoeven et al. 2016, p. 91)

With regard to the frequency of PC use, it is remarkable that the age at the time of first using a computer and self-study are significant predictors for frequency of use for non-study purposes, but not for study. The younger the students were when they started using a computer or the more they

invested in self-study, the more they use a PC for non-study purposes. Peers also play an important role, both for study and for non-study purposes: when students learned from peers and/or are supported by peers, they spend more time on a PC. Two of the contextual factors have some

meaning for computer use (both for study and non-study purposes): women use a PC less than men do, and humanities students use a PC more frequently than science students do. ICT courses in secondary school and the education level of parents, however, do not contribute to a better prediction of PC use.

The prediction of the frequency of using ICT instruments for both study and non-study purposes can be significantly improved by two variables. Again, these are the starting age of computer use and peer learning. For non-study purposes, the domain of study and peer support can be added: students in the humanities and those who enjoy more support from peers have a higher chance of more frequently using ICT instruments for non-study purposes. Other variables do not seem to have a significant meaning for the frequency of use of different ICT instruments.

The frequency of use of ICT programs for study and non-study purposes is more sensitive to the variables of the learning experience model. A young age of first using a PC, support from peers, and self-study allow better predictions for the frequency of use of ICT programs. In addition, the domain of study of the student creates better predictions: ICT programs will be used more by science students than by humanities students for study purposes, but for non-study purposes, the reverse is true. It is also shown that women use ICT programs less frequently for study than men do and that students who learned more from teachers and peers about ICT will use ICT programs for study more often. Although attending university courses in which a computer is used does not explain significantly the mastering of ICT skills (see section “[Learning Experience and Identity Commitment as Predictors for ICT Skills](#)”), this variable is a significant predictor of the frequency of the use of ICT programs for study. Moreover, regression analysis shows that it lets the difference between male and female students disappear, which implies that the study situation contributes to a more frequent and more gender-equal use of ICT programs.

The second model expresses the relevance of identity commitment for the frequency of the use

of a PC, ICT instruments, or ICT programs by students. Here, two important factors of identity commitment are the students’ professional orientation (Profor) and their belief in their own academic capacities (Acadsc). However, it turns out that this model does not have much explanatory value for either the frequency of use of a computer, ICT instruments, or ICT programs.

The identity commitment model explains 5.3% of the variance in frequency of PC use for study and 10% for non-study purposes. All other R^2 values are smaller or almost equal to zero.

In the identity commitment model, the best predictor for the frequency of use of a PC is the conviction of students that a researcher needs sufficient ICT knowledge. The more they believe this, the more frequently PCs are used, both for study and non-study purposes. Frequent use of a PC for study is also supported – and this is not what was expected – by a stronger intention of the student to become something other than a researcher and by a stronger orientation toward a profession. Frequent use of a PC for non-study purposes, in turn, is supported by the belief of a student that ICT is needed to carry out scientific research. In addition, the contextual factors are good predictors for PC use. Female students spend less time on a PC than men, and science students less time than humanities students.

Students who think that researchers need appropriate ICT knowledge will use all kinds of ICT instruments more often for both non-study and study purposes than those who do not hold this opinion as strongly. This is also true for students (as far as they need the instruments for study purposes) who are more vocationally orientated. Moreover, students with a positive attitude toward research will more frequently use these ICT instruments for study than other students will. However, unexpectedly, students who are more inclined toward becoming a researcher will use all these ICT instruments less often. With regard to non-study purposes, the more positive students are about their academic capabilities, the more they use ICT instruments; humanities students will use ICT instruments more frequently than science students. It should

be noted that gender and having attended an ICT course in secondary school are not adequate predictors here.

The use of ICT programs for both study and non-study purposes can be predicted by ICT_science and gender. Students who believe that researchers need a good knowledge of ICT will use ICT programs more than other students will. When programs are used for study or non-study purposes, the scores for male students are higher than for female students. Students who are aiming for an occupation other than a researcher also use ICT programs more frequently for non-study tasks than other students. It should be noted that ICT course experience in secondary school and the education level of the parents do not contribute to making better predictions for the frequency of using ICT programs.

Conclusion

In this article, two hypotheses regarding the ICT skills and the frequency of ICT use by university students were presented. In line with Dewey's learning theory, the first hypothesis is that a positive ICT learning experience at home, in school, and with peers will contribute to a higher level of mastering ICT skills and a more frequent use of ICT among bachelor's students (the learning experience hypothesis). The second hypothesis is based on the use of ICT in research and the similarity between the structure of information systems and scientific research. From this, it was hypothesized that students who strive for an identity commitment that is directed toward scientific research will be more inclined to learn ICT skills and show a higher frequency of ICT use. Both hypotheses are tested with the inclusion of some important contextual variables: gender, domain of study, ICT course in secondary school or at the university, and the education level of parents.

The explanation of different levels of ICT skills provided by the learning experience model is confirmed, but not very strongly overall and not equally for all types of ICT skills. The model can explain the largest proportion of the variance

in maintenance of a computer and the technical use of a browser. In descending proportion of explained variance, these two skills are followed by the three of working with a spreadsheet, communication skills, information collection with a browser, working with databases, two forms of working with a presentation program, and working with a word processor.

The best predictors for most of the skills are the age of the students when they first started using a PC (the lower the age, the higher the scores), self-study, gender (men score higher than women), and having attended an ICT course in secondary school. Instruction from teachers is important for working with spreadsheets and databases. It is also noteworthy here that the use of a PC at home and at work by parents and siblings, what the student learned of ICT at home, and the support of peers and teachers do not play a significant role, although research has shown that these factors are important in primary and secondary schools (Vekiri 2010; Aslanidou and Menexes 2008; Barron et al. 2010; Zhao et al. 2010).

The learning experience model also explains some of the variance in the frequency of ICT use. It explains 17.5% of the variance in the frequency of PC use for non-study-oriented tasks, but for all other frequency-related dependent variables, the proportion of explained variance is much smaller.

Predictions of the frequency of ICT use can be improved taking into account the age when students started to use a PC (the lower the age, the higher the use), self-study (only for non-study purposes), domain of study (humanities students mostly score higher than science students), and gender (women score lower than men). Peer support is a significant predictor for the frequency of computer use and of ICT programs, and this applies to both study and non-study purposes. What had been learned at home is not recognized as a factor that could predict the frequency of ICT use by the students. This is the same for ICT courses attended in secondary school and at the university or the education level of the parents.

The identity commitment model also explains parts of the variance in the ICT skills of students. The explained proportion of the variance,

however, is very different for each of the ICT skills. This model explains two fifths of the variance in the technical use of a browser, but for all other ICT skills, the results are lower, sometimes substantially so. The most important predictors of this model are the belief of students that researchers need an appropriate knowledge of ICT, a positive attitude toward scientific research, gender (lower scores for women than for men), and having attended an ICT course in secondary school. The other explanatory variables have very diverse impacts. Each of them improves the prediction, but for very different ICT skills. The reasons why these differences occur are unclear and require more research. It should also be mentioned that the intention to become a researcher is not a strong predictor: only the skill to perform style changes in spreadsheets seems to be better developed among research-oriented students.

The identity commitment model is less successful in explaining the frequency of ICT use. Only one explanatory factor plays a significant role in the explanation of the six dependent variables, i.e., the belief of the students that researchers need ICT. The more students think that a researcher needs a good knowledge of ICT, the more frequently they use a PC, ICT instruments, and ICT programs – and this applies to both study and non-study purposes. The other factors do not have the same predictive value, and their value differs for each of the dependent variables. In other words, the hypothesis that students who want to become a researcher will score higher for using ICT is not supported by the data. On the contrary, students who want to become a researcher do not show more frequent use of a computer or ICT programs, and they actually use ICT instruments for study less frequently than other students do.

In short, the learning experience hypothesis and the identity commitment hypothesis are both only partially confirmed by this research. In general, however, it can be concluded that a relationship does exist between the ICT learning experience, the research-oriented identity commitment of bachelor's students, and their command of ICT skills on the one hand and the frequency of use of a computer, ICT instruments,

and ICT programs on the other. However, this is a very diversified relationship, which is not always equally strong for all aspects of ICT skills and ICT use. To better understand these differences, future research will have to dig deeper into the particularities of divergent ICT skills and ICT uses.

Introduction

Primary school classrooms are filled with diversity that constantly challenges the teacher's role as facilitator of the development of children's writing process skills. However, many teachers feel unable to help their students overcome

their writing problems and feel that students don't like these activities (Graham et al. 2007). As a result, the reasons for these difficulties, presented by teachers, highlight the lack of training, time, or skills to respond to the current literacy needs of children, where writing communication can occur in analog or digital formats (Araújo 2017; Graham and Harris 2013).

In recent years we have witnessed rapid changes and advances both in the writing process and in the resources used for writing, strongly marked by the present and dynamic role of ICT. These have created opportunities and challenges for the development of children's writing, whether through social networks, facilitating access to information, or by diverse forms of writing (Buckingham 2013; CAST 2011; Edwards-Groves 2011; Tavares and Barbeiro 2011).

Today, children are becoming experienced users of digital communication and are increasingly familiar with digital and online writing in a variety of contexts (smartphones, tablets, PCs). This form of writing began by using different channels (phone, email, and Internet) and has assumed different modalities (sounds, gestures, iconographic symbols, animations or even the abbreviation of words or phrases) that are accessible to students at an earlier age (Kilpatrick et al. 2014; Graham and Hall 2016). Thus, writing appears more and more as a social act in a network that has become a necessity in our world today (Graham and Rijlaarsdam 2016; Moore and MacArthur 2016; Prensky 2005; Selywn et al. 2010).

In this context, writing implies the in-depth knowledge of the various contexts and situations of written communication, including the use of technologies (Bazerman et al. 2017). Currently, in a semiotic perspective and multiliteracies, writing assumes a multidimensional and dynamic nature that integrates the use of linguistic, visual, spatial, gestural, and audio characteristics, as well as emphasizes the role of design (in production and presentation) in the construction of textual meaning, where visual representations of ideas gain space (CAST 2011; Campbell and Ballast 2011; Cope and Kalantzis 2012; Rose et al. 2005; Rose and Meyer 2006; Wolf et al. 2016).

Technologies can also help the teaching-learning process by promoting motivation; facilitating the access; monitoring and evaluation of knowledge by the student and teacher; and differentiation and pedagogical alternatives to allow the involvement of the school community with the world and also to facilitate administrative work in the school context (Araújo 2017; MacArthur 2009).

The use of technological web resources in writing can, for example, facilitate immediate access to information; the possibility of exploiting individual interests and/or clarifying real-time doubts and exploiting various communicative spaces (e.g., interpersonal, virtual, digital, and textual) or acquisition and collective intelligence. However, they also present some constraints, such as: difficulty in analyzing, selecting, and processing information that can lead to cognitive overload and disorientation. Therefore, students need to learn (e.g., how to locate, evaluate, and select or synthesize relevant information) (Leu et al. 2004; Jenkins 2006). Also the use of digital resources (e.g., multimedia) can facilitate access to multiple forms of communication (e.g., text, image, audio narration, and animations/videos) (MacArthur 2009; Prensky 2005) and reduce the cognitive load in working memory and improve information processing, which enhances the understanding of the transmitted message together with the tools and applications that facilitate the construction of knowledge and reflection (e.g., semantic networks, search engines, visual representation tools) (Mayer 2005; Vue et al. 2015).

The fundamental and powerful role of ICT in classrooms is no longer questioned, regardless of the many different forms of action. In the light of the research, we know and recognize the benefits of several technological resources such as word processor, word predictors, grammatical or speech synthesizers, digital books, or blogs (Thompson et al. 2016). Thus, it has a set of facilities that ICTs provide, in particular, immediate feedback, the presentation of information through a variety of multimedia formats [that can favor the visual and aural view], allow the sharing of activities and the development of collaborative and interactive practices, enable visually attractive writing, allow for the

reorganization of the text, contribute to the dissemination of information and develop audiences in the process of writing texts and writing self-esteem (Araújo 2017; Thompson et al. 2016; Smedt and Keer 2014).

Thus, since the process of writing is a constantly changing act of communication, the use of ICT is not only limited to its use as a tool but to a change in the way we understand writing and its learning in a constantly changing social context. Despite this, there is, on the one hand, a resistance or a lack of focus on the use of ICT in education (MacArthur 2009); on the contrary, there is a very strong relationship established between ICT and school or professional writing (Tavares and Barbeiro 2011). However, many teachers feel insecure in teaching the writing process using technology (Araújo 2011, 2017; BECTA 2004, 2007). The impact of writing interventions using technologies in the inclusive primary classroom context, where teachers try to adapt the teaching process to the characteristics and needs of all students, has also been lightly studied. Technologies in writing can have a positive or negative effect on learning depending on how well teachers and students take advantage of their abilities, often influenced by the type of instruction in the learning activities with the technologies and using these resources (MacArthur 2009).

Several authors have referred to the need for more research on writing, both digital and handwriting, by children and using ICT (Peterson-Karlan 2011). For the above reasons and because we recognize the need to carry out studies that explore and exemplify how to take advantage of the potential of using ICT in writing practices in inclusive primary education classrooms, a practical example is presented below explaining possible steps, processes, and activities that can be performed by teachers in the classroom.

Strengths and Challenges of Using ICT in Classroom Writing Contexts

It is relevant to know the strengths and challenges of using these resources in the classroom before using ICT in classroom teaching interventions

(Bazerman et al. 2017). In this way, it will be possible to make more informed decisions and anticipate procedures to deal with the possible challenges of the difficulties that can be encountered.

Considering the inclusion of ICT in writing practices in the primary school classroom context and the new environments and formats of written communication, an exploratory study was carried out with a proposal for the exploration of classroom writing intervention in opinion essays (linear and multimodal, using, i.e., images, sounds, and text) by 4th grade Portuguese students considering the implementation of an inclusive curriculum, which will be presented as an example of how to operate the use of ICT in classroom writing interventions, and the articulation of theoretical recommendations for the learning process of writing in the classroom context using the ICT potentialities to promote improvement of writing quality, particularly of opinion essays.

Phase I – Definition of Theoretical Foundations

The planning of classroom-based interventions using ICT to improve writing skills should involve addressing three key areas: *The pedagogical area* represents the options regarding the strategies and methodologies to adopt, i.e., setting goals, authentic writing contexts, dictation of students' texts, writing-reading relationships; active or expositive methodologies; use of strategies that promote the management of behaviors and thoughts by the student to reach a certain goal – self-regulation, or learning by trial and error; individual and/or collaborative teaching. The *knowledge area* represents the knowledge about the subjects involved in the students' learning processes, i.e., linear and multimodal writing process; explore multiple means of representation such as visual or auditory; and the process of teaching writing. And the *ICT area* represents the possibilities of using ICT resources and the knowledge of the potentialities in the process of teaching learning, i.e., word processor; spell checker; mental maps; speech synthesizers; and others (Araújo 2017; CAST 2011; Mishra and Koehler 2006). The articulation between these

three areas will guarantee the previous knowledge of the teacher on the subject to address the way to operationalize learning to promote the learning process of the students and the options of the resources at their disposal, while being aware of the necessary care according to the various available options. The anticipation of possible difficulties or constraints will allow the teacher to plan possible alternative solutions to deal with situations that may arise (Araújo 2017). For example, if a specific program is going to be used in the classroom, it is important that the email and password that allow for the installation of applications or programs on the devices is safe which is especially important when using devices from families.

As previously mentioned, the learning process of writing, linear and multimodal, in the twenty-first century is more complex and challenging than the different forms of writing, with multi-literacies (Cope and Kalantzis 2012; Kress 2003), and writing contexts such as the need to change the “traditional” pedagogical practices of a society lacking in ICT resources for innovative practices that create new learning opportunities (Kilpatrick et al. 2014). It is, therefore, advisable to include in the current practices, the approach so that the teacher can create new opportunities of essential aspects such as: creativity, communication, and collaboration (Bazerman et al. 2017; Buckingham 2007; Graham et al. 2012; Jonassen 2007).

Universal Design Learning (UDL) suggests that it is essential to provide access to multiple means of representation (perceptions, language and symbols, and comprehension), multiple means of action and expression (physical action, expressive skills and fluency, and executive functions), and multiple means of engagement (recruiting interest, sustaining effort and persistence, self-regulation) (CAST 2011), for more information see: <http://www.cast.org/>.

Currently, intervention with the greatest scientific evidence for the promotion of writing is the Self-Regulated Strategy Development model (Harris 1982). This specific framework for an instructional strategy promotes explicit teaching and guides students in the writing process through self-regulation strategies such as: goals-

settings, self-monitoring, self-talks, and self-reinforcement. SRSD is composed of six stages: active background knowledge, discuss it, model it, memorize it (mnemonic and practice the strategy), support it, and independent performance. These steps are not linear, and a step can be returned to whenever necessary. Over time there is a progressive and gradual transfer, according to the competences and abilities demonstrated by the student, of the responsibility of the learning process of the teacher to the student (Harris et al. 2008). For more information about SRSD, please consult <http://www.thinksrsd.com/>, <https://course.srsdonline.com/cart/>, for example.

Finally, it is also recommended to promote a teaching process that promotes the development of actions in students that stimulate their learning, gradually increasing its complexity in order to make them autonomous in the application of acquired knowledge and skills, suggesting the use of Revised Blooms' Taxonomy (Anderson and Krathwohl 2001), namely, the promotion of activities that include remembering (recalling relevant knowledge), understanding (making sense), applying (using the knowledge), analyzing (breaking the concepts into parts), evaluating (making judgments based on a set of guidelines), and creating (innovating).

Phase II – Profile Identification of Students and Contexts

There are some factors that influence writing classroom intervention using ICT identified by researchers such as: (a) previous experience and knowledge; (b) involved community elements; (c) resources and conditions (i.e., teaching environment, methods, and strategies); (d) group management (i.e., group organization, time, individual differences, individual and group dynamics); and (e) proposed activities (i.e., proposal, implementation, and pedagogical evaluation) (Araújo 2017; MacArthur 2009; Tavares and Barbeiro 2011; Kilpatrick et al. 2014). Furthermore, researchers have reiterated the need to create explicit and context-specific responses (Harris and Graham 2016).

Gathering information on some of these factors will help in the use of strategies, methodologies,

and resources tailored to the needs, abilities, and potentials of the students and contexts in which the classroom writing intervention is developed.

The use of surveys, scales, interviews, and/or written productions to student, family, and colleagues can help in obtaining important information (e.g., Bruning et al. 2013; Graham et al. 2012). It is advisable, for example, to collect information on *students' profiles*: (a) perceptions about writing knowledge, attitudes, and self-efficacy, (b) writing performance, (c) writing practices, (d) academic course, and (e) learning profile; and *learning contexts*: (a) pedagogical practices in the classroom and at home, (b) facilitating or hindering elements, (c) interpersonal relationships, and (d) personal characteristics of group elements (Araújo 2017).

Some resources such as the following can help gathering information about the students' profiles and context, namely: Scale about students' Approach to Writing; Scale about students' attitudes and motivation, and Scale about students' self-efficacy in writing; Scale about structural elements in opinion essays (e.g., one point for the presence of each topic sentence, reasons, arguments, examples, and final sentence); writing survey instrument about writing practices; scales about approach to writing with ICT, writing attitudes with ICT, and writing self-efficacy with ICT; and essay length by word count and number of connectors. For information on the authors of these instruments, please consult Araújo (2017).

This information may be helpful, for example, for students with low perceptions of self-efficacy who generally tend to give up on tasks more easily (Araújo 2017). Therefore, knowing in advance the characteristics of learners can help define ways of approaching writing using ICT with these students (i.e., use greater enthusiasm, reinforce student successes). Also, students with reduced experience of using ICT resources may present some difficulties or need practice in writing with a keyboard or to understand the different communication spaces. Another possible example may be the observation of possible discrepancies between students' perceptions and their actual performance in writing,

since it should be approached with greater care in presenting the aspects to be improved among those who present more misconceptions (Araújo 2017).

Phase II – Goals Setting

Goal setting is an evidence-based practice in writing (Harris and Graham 2016). Thus, before the beginning of the intervention, it may be important to clearly define each student's goals to reach at the end of the intervention, which should be individualized (Araújo 2017; Graham et al. 2013). Therefore, it is possible to define a general objective: to improve the writing of opinion essays, for example, and a specific objective: the use of more diverse words, better organization of essays, or making fewer errors when essays are written, for example.

The goals selection criteria may consider the results obtained in the student's performance in the evaluation, considering the area that the students presented more difficulties in writing quality essays (Araújo 2017). However, this process must involve each student through the students' obtained feedback from the evaluation obtained in the pretest and according to the results defining the specific objective. If the student and the teacher have considered other pertinent goals, they can readjust them. The students were informed that at the end of the intervention they would have achieved their goals, looking for a commitment of the student to strive for the desired results and achieve the initial objectives. These goals can and should be adjusted and increase in complexity whenever they are achieved. This phase will help the student to think about what is intended and to anticipate behavior that will help them achieve their goals.

The students had the opportunity to observe the results obtained in the pretest, where they were asked to write an opinion text based on a question, regarding the quality of the texts produced (e.g., theme and typology; information coherence and adequacy; structure and cohesion; morphology and syntax; vocabulary repertoire; spelling) (source: Scale from Portuguese National Jury of Examinations of the Ministry of Education, 2011) and the structure of the text (number of elements

present in the text: opinion, reasons, counter-reasons, examples, and final sentence) (for more information's about these resources, please, see Araújo 2017). They also observed their perception of knowledge and attitudes in the writing of texts with and without recourse to technologies (1 = strongly disagree and 5 = strongly agree), as well as the perception of self-efficacy with and without recourse to ICT (percentage scale between 25%, 50%, 75%, and 100%), adapted from Pajares and Valiante 2006). After identifying the areas in which the students presented greater difficulties, two objectives were defined for each student, which included a general objective: improving the quality of the text and a specific objective (Araújo 2017).

Phase III – Classroom Writing Intervention

This classroom writing intervention, called SRSD + ICT model (Araújo 2017), was based on multi-based theories, especially the SRSD model, and involves evidence-based practices (defined in phase I). In interventions in a large group, attention should be given to the multiple agents involved in the classroom writing activities (considering the information collected in phase II) which is intended to be adaptable to individual and group characteristics of students.

In the same way, and whenever possible, we will seek to promote early detection and intervention in writing problems. In this way the classroom writing intervention will integrate the regulated use of ICT in the learning process of writing, both in terms of resources with potentials in the learning process of writing, using twenty-first century writing tools as defended by Graham et al. (2015).

This intervention lasted 12 weeks, with 1 weekly session of 90 min. Each session had a specific objective which will be described below:

Session 1: Exploration of knowledge about the writing process and contexts of writing, as well as textual genre and associated characteristics (classroom group).

Session 2: Discussion about what good or bad opinion texts are by observing and analyzing examples (classroom group).

Primary School Classroom Writing Interventions Using Technologies, Fig. 1 Mnemonic “DUCK” + “Structure”

Session 3: Modeling of the writing process of an opinion text by the teacher with the participation of the students from the idealization to the publication of the text. Including the use of self-talks, self-monitoring, self-assessment, and self-reinforcement (classroom group);

Session 4: Memorization of the Mnemonic “DUCK” + “Structure” (Araújo 2011) in order to facilitate the recall of key information used to remember the steps that must follow in the writing of all texts, “DUCK,” and opinion essays, “Structure,” visible in Fig. 1 (classroom group);

Session 5: Exploration and discussion of knowledge about writing (linear and multimodal) and the potentials and contexts of ICT use in writing (classroom group);

Session 6: Modeling the use of ICT in writing opinion texts, exploring tools such as: word processor; spelling checker; mental maps; speech synthesizers; and others, as well as ways of conducting research to assist in the preparation of an opinion essay (Classroom groups involved in the components of classroom writing intervention using ICT (please see, Fig. 2));

Session 7: Support practice for writing opinion essays using the ICT tools previously addressed. Reflection on the utilities, potentials, and constraints in the use of ICT resources (small groups: 3–4 students);

Session 8: Support practices for writing opinion texts, with or without recourse to ICTs,

according to the opinions of the students and the teacher (small groups: 3–4 students);

Session 9: Modeling the use of ICT in the writing of multimodal opinion texts, using rainbow mnemonic (Araújo et al. 2019), exploring programs that involve image, sound, and video editing and multimodal opinion essay writing practices, using image, video, and sound editing programs (small groups);

Session 10: Specific work in the area related to the specific objective: (a) theme and typology – identification of different types of text and characteristics; (b) information coherence and adequacy – identification of gender, grade or tense concordance, synthesis of ideas, and correction of ideas in sentences; (c) structure and cohesion – identification of the essential aspects of texts (e.g., introduction, development, and completion), reinforcement of the learning process stages, and variations, as well as the exploration of the distinction between sentences and paragraphs in a text; (d) morphology and syntax – identification of syntactic and no synthetic sentences; (e) vocabulary repertoire – construction of word families, vocabulary areas, and identification of simple and compound words; and (f) spelling – rules explanation and training/group play: identifying the rules and the correct spelling (small group/individual);

Session 11: Sharing experiences with colleagues, e.g., explanation of what they did and what they learned and reading produced texts (if

Primary School Classroom Writing Interventions Using Technologies,

Fig. 2 Components of classroom writing intervention using ICT

any). Writing practice of opinion essays in pairs (pairs); and.

Session 12: Independent practice of writing an opinion essay (individual).

It is also fundamental that, throughout the intervention, students should talk to other students in a language which is accessible and according to the language they normally use, facilitating the input of the strategies, steps, and information presented. This includes explicit thinking and communicating with students to reflect on how the strategies they have learned throughout the intervention can be transferred to other contexts. Lastly, whenever possible, the student and the teacher must focus on specific goals through the individualization of pedagogical practices (Araújo 2017).

Phase IV – Intervention Assessment

After the intervention, it is advised that students write an opinion text based on a question, which should be then evaluated in terms of quality, text structure, length, and number of argumentative connectors (posttest). It is further advised that students complete questionnaires with their opinions of the intervention and specific components

addressed in the intervention. After 6 weeks of the end of the intervention, the students should write other opinion texts that will be later evaluated in the same categories as pretest and posttest (follow-up). Subsequently, the students can compare the results obtained before, after, and 6 weeks after the intervention and verify whether they were able to meet the goals set out at the beginning of the intervention (Araújo 2017).

Students' Writing Performance

It was verified in the results of this exploratory study (Araújo 2017) with five 4th school grade classrooms in Portugal (87 students), definite improvements in students' writing performance and students' self-efficacy perceptions in writing, an increase in students' knowledge of writing, and students' knowledge of the potentials of ICT in the writing process. Similar results from previous studies confirmed that instructional writing practices promote improvements in students' writing performance (e.g., Graham et al. 2012, 2013; Prata et al. 2015; Festas et al. 2015) and ICT approaches in the writing process can produce improvements in writing performance (e.g., Tanimoto et al. 2015; Santangelo and Graham 2016). Also, the positive relationship between

the perceptions of writing self-efficacy and writing performance had already been verified by other authors (e.g., Bruning and Kauffman 2016; Pajares 2003).

The students' performance obtained in this example of ICT implementation in classroom writing intervention indicates that most of the students improved their results regarding the structure, quality, and number of linking words used in the essay opinion, resulting in improvements with greater effects than expected, exceeding those observed with the most effective interventions in writing (Araújo 2017). From the above, part of the intervention success can be attributed to the compilation of various evidence-based writing practices highlighted by Harris and Graham (2016) among other researchers (e.g., prewriting activities, explicit and direct teaching, modeling, feedback, authentic learning, peer support and review, use of self-regulation and metacognition processes, promotion of independence, reinforcement of the relationship between reading and writing).

These results reinforce the positive effect of ICT in students' writing process, already evidenced in previous studies, and self-regulated use of ICT in the process of learning to write.

Also, students' goals were able to improve their performance in writing opinion essays (98.9%) and 96.6% of students were able to improve their specific goals (Araújo 2017). In addition, the ability for students to regulate and control their learning process and to choose various writing tools and formats, as well as listening and respect for choices, previous knowledge, and individual characteristics may have contributed to their meaningful attribution, regarding their writing learning process.

In the final survey, the students identified some of the programs they liked most during the intervention. The use of writing programs (82.8% of students) and Internet use (71% of students). Among the resources used, those which presented a lower percentage were dictionaries and similar courses (28%). However, there were very different perceptions of the students according to the usefulness in ICT for writing (Araújo 2017). These differences between students are expected,

and it is consequently essential to observe and record them in the context of educational investigations, serving as a basis for further study in order to provide indicators of different forms of action by education professionals (Bazerman et al. 2017).

Therefore, the intervention allows students to control their learning, that is, regulate the use of ICT and writing strategies for the learning process allowing, reinforcing the importance of self-regulation as indicated in several previous studies (e.g., Hattie 2009; Graham et al. 2007, 2012; Graham and Perin 2007; Graham and Rijlaarsdam 2016; Harris and Graham 2016), to produce better results than when it is the teacher who performs this role. In this way, all the students experimented with different tools and had the possibility to choose whether to use a certain tool during the writing process. The possibility of being able to respect the students' perceptions of the usefulness of ICT throughout the writing process, or whether or not to use them like any other tool, was considered very positive by the students.

Reinforcing students' critical thinking about the most appropriate tools and strategies for each student present in this intervention operationalized the importance of developing this competence and building collaborative networks defended by Jonassen (2007), among others, which may have assumed with a positive aspect that contributed to the results achieved.

Finally, the students' independence in writing was stimulated and, together with the teacher, each student decided if and when to use ICT for their writing process, as well as using other forms of writing to help their writing process (e.g., auditory, visual), as advocated by several researchers (e.g., Campbell and Ballast 2011; Cope and Kalantzis 2012; Edwards-Groves 2011). It should also be noted that the ICT resources of the students' families, including computers, tablets, and mobile phones were used and that the introduction of these technologies in the classroom for writing promoted more active and proactive dynamics among students. This intervention followed the recommendations of Boyle et al. (2015) who advocates pedagogical practices guided by clear, explicit, practical,

scientifically validated, and teacher-oriented instructions according to the individual needs of the students in the class and the educational goals to be achieved.

Conclusions and Implications

It was possible to include the use of ICT in the classroom writing intervention, following the guidelines of the scientific community, which sought to respond to the profile of the student and the context, as well as to articulate methodologies and strategies of pedagogical intervention with the aim of promoting adjusted responses to all students, taking into account the individualization and personalization of learning in the classroom context. Although not all pupils were able to achieve improved writing quality of opinion texts, the results of about 99% of pupils who achieved their goals after the intervention proved superior to previously undertaken and promising interventions; however, more research is needed to articulate the modification of teaching methodologies and strategies in writing appropriate to the new resources and contexts of writing, including the possibilities of the use of ICT and multimodal writing.

As previously identified, ICT was considered as a possibility highlighting the importance of students having the knowledge and experience to help them make effective decisions to improve their skills, knowledge, and performance in writing. At the same time, the use of self-regulation strategies proved to be an asset in the progressive development of students' autonomy in the writing process, exploring the different contexts and potentialities and adjusting the school reality to the surrounding social reality. Given the promising result obtained, it is considered relevant to carry out more studies in several contexts, in order to understand the implications of interventions as suggested by the students. Finally, it was also possible to promote early detection and intervention of writing problems both individually and in groups, focusing on the individual and is adjustable to the characteristics and needs of students.

Introduction

Historically programming has not been a subject studied at second level in Ireland, and degree programs in Irish third-level institutions have assumed students have no prior experience when approaching the teaching of programming. It has become apparent that increasing numbers of students arriving into undergraduate computing and engineering degree programs in Irish third-level institutions have previous exposure to computer programming, and the situation regarding the teaching of programming in the Irish school system is currently changing. This entry describes the current state of programming experience of Irish undergraduate students on entry to third level, exploring its sources and impact and presenting some comparative international context.

Irish School System

What follows is a brief overview of the structure of the Irish school system in order to provide a context for the following discussion. The Irish school system is made up of primary and second-level education. Primary education consists of an 8-year cycle: junior infants, senior infants, and first to sixth classes. Pupils normally transfer to second-level education at the age of 12. Second-level education begins with a 3-year junior cycle after which students take the Junior Certificate examination. This is followed by a 2-year or 3-year senior cycle depending on whether an optional Transition Year is taken following the Junior Certificate examination. Transition Year is free from formal examinations and allows students to experience a wide range of educational inputs, including work experience. Following their final 2 years in the senior cycle, students take the terminal state exam known as the Leaving Certificate.

Programming Opportunities for Irish School Students

Historically the standard introductory programming course at third level in Ireland assumes no prior knowledge of programming, as it has not been taught as part of a formal subject in the Irish school system. Although a module in

Computer Studies was made available in the 1980s as an optional component of the Mathematics Leaving Certificate subject, it lacked a clear syllabus, and nationally uptake was low. Limited resourcing due to the prevailing economic conditions in the 1980s and early 1990s together with a lack of a clear national policy restricted the ability of schools to develop the teaching of programming.

However, this situation is currently evolving, largely in response to industry demands in the face of a perceived skills gap. This is in line with an international resurgence of Computer Science education in schools. In 2014 an optional short course in Coding was introduced which can be taken during the junior cycle of second-level schooling and Computer Science is being introduced as an optional Leaving Certificate subject in September 2018. Furthermore, the National Council for Curriculum and Assessment (NCCA) is actively considering approaches to introducing the teaching of programming to all students in primary schools through its *Coding in Primary Schools Initiative*. It is clear that third-level institutions will need to adapt to cater for this new generation of students with prior programming experience.

In addition, outside of formal educational settings, recent years have seen a surge of interest in learning to program as evidenced by the phenomenal success of the CoderDojo network of after-school programming clubs. Since its foundation in 2011, the CoderDojo network has grown exponentially to include over 200 clubs across Ireland in January 2017, and the academic community in Ireland has become aware that many students arriving at third level to commence computer science and engineering degree programs already do so with some prior exposure to programming.

Prior Programming Experience of Third-Level Students

Overview

A repeated cross-sectional study using an annual survey of third-level students is currently

underway in Ireland (Strong et al. 2017). It provides empirical data on what programming knowledge and experience students have before commencing undergraduate degree programs with a programming component in Irish third-level institutions and explores how this exposure affects their experience of programming during their freshman year. Data from the 2015/2016 and 2016/2017 academic years of this survey give a view of the Irish student experience and are suggestive of emerging changes. The survey population is freshman students undertaking a third-level, undergraduate degree program in Ireland which involves the studying of programming in first year. Such programs are typically computer science and engineering programs. Students are targeted in the latter part of the second semester of their freshman year, so they can make a judgment with regard to the impact of their prior experience on their current studies.

While the overwhelming majority of the survey population would have undergone their second-level education in Ireland, it should be noted that as of the 2014/2015 academic year, approximately 10% of students in Irish third-level education are “international” students and a number of these students would have experienced some level of formal exposure to programming in their previous education.

From 2016, the survey was circulated to freshman students of eight institutions. The survey collected demographic data such as third-level institution attended, age, gender, and degree program. It then asked if respondents have prior experience. For those that do the remaining questions explored the nature of that experience and its impact on their current study of programming. It should be noted that as students self-assessed their level of confidence and ability, rather than an objective test being applied, this may have introduced some bias, though it is not clear in which direction this may lie.

The early results of this study, while limited in their scope, provide the only indication of the current situation as well as a baseline from which to evaluate the inevitable further changes in the Irish student profile. They are therefore discussed in detail below.

Participants

The sample size for 2016 was $n = 321$ respondents and for 2015 was $n = 122$. Currently in Ireland, female enrolment figures for full-time honors degrees are approximately a mere 15% for computing degrees and 18% for engineering degrees (<http://hea.ie/statistics/>). In the survey there is therefore a slight overrepresentation of female respondents over the 2 years at 25% across the 2 years. Mature students range between 8% (universities) and 20% (institutes of technology) of the student population; the survey participants are generally in line with this.

Programming Experience

Two thirds of Irish students in the survey indicated that they had *no* prior exposure to programming with 34.2% indicating they had some experience prior to the start of their third-level course. These figures are not significantly different from those of the 2015 survey where 63% of freshman students ($n = 120$) indicated they had no prior experience.

Students were also self-reported their prior level of fluency in programming. The 2016 cohort reported having a much stronger level of fluency than the 2015 respondents (see Fig. 1 for figures and an explanation of fluency levels).

The proportion of Irish students reporting programming experience prior to third level highlights the relatively low level of experience the Irish students have at the outset of their third-level study. This is most likely due to the majority of students coming directly from Irish second-level schools where programming is not yet widely taught. It is notable that the level of fluency reported suggests that for the students who did have experience their previous studies were often deep and considered.

Programming Languages

Students have clearly engaged with a wide variety of languages which is an indicator of the diversity and range of the sources of prior experience. They are outlined in Table 1.

Differences in the survey format between the years are believed to be responsible for the stark difference between the reported exposure to the popular “Scratch” educational language.

Prior Programming Experience of Undergraduate Computing and Engineering Students in Ireland, Fig. 1 Level of fluency from 2015 and 2016

Helpfulness of Experience

10–15% of students reported that their prior experience was not helpful in their freshman year. The responses from the remaining students who did report an impact fell into the following broad categories:

- A head start boosted confidence helping students transition to third level.
- Not struggling with the basic concepts allowed for deeper learning to occur.
- Understanding fundamental concepts helped in adapting to new languages.
- More receptive to understanding complex concepts.
- More time could be spent on studying other modules.

As we might expect, prior exposure to programming concepts is considered helpful when dealing with introductory programming modules. Interestingly, this doesn’t necessarily relate directly to the conceptual knowledge and skills gained from prior experience but instead is on the affective impact of having such knowledge particularly in the area of confidence levels and receptiveness to new learning. This underlines the importance of educators adopting pedagogical approaches that support the growth of confidence in learners. Given the diversity of programming tools and skills encountered, it’s perhaps not surprising that familiarity with the core concepts of

Prior Programming Experience of Undergraduate Computing and Engineering Students in Ireland, Table 1 Programming languages experienced prior to third level

Language	2015 freshmen (n = 48) (%)	2016 (n = 106) (%)
C, C++, C#	33	40
HTML	60	28
Java	44	59
JavaScript	23	17
Other	0	22
PHP	0	12
Python	25	33
Scratch	38	1
Basic variants	4	14

programming had a significant positive impact. Since many introductory programming modules focus on trying to impart these core skills, students who have a head start reported that they can focus purely on advanced constructs or even on other modules.

When students were asked if any specific aspects of their experience were helpful to them, one third indicated that there was nothing specific that was useful.

With the remaining responses, the most frequently cited helpful activities were time spent on projects or practice (19%) and specific online or print resources (15%) notably Codecademy and YouTube.

The fact that a substantial number of students were unwilling (or unable) to identify individual sources of their experience as being helpful could indicate that nothing at all, or no single specific aspect was helpful. However, alternative readings could suggest that they either had difficulty in reflecting on its effect or that their overall experience – rather than specific experiences – was helpful.

Origins of Experience

A particularly interesting question in the Irish context, where programming has not been widely available as a formal school subject and grassroots organizations like CoderDojo report considerable activity, is where students are gaining their experience. Multiple sources for their experience have been reported.

School Activities: 27% indicated that they had participated in programming activities through school. These activities were identified as short summer classes, Transition Year courses (a 1-year program in Irish second-level schools with no formal exams prior to beginning the 2-year terminal examination), elective classes, preparation for programming competitions, and a formal part of school curriculum (international students). The duration of these activities ranged from 1 day to 2 years.

Club Activities: 13% of students reported participation in clubs or groups outside of school. These included CoderDojo and other computer clubs, third-level access and youth programs, as well as adult education courses.

Online Activities: Reported participation in online courses (including courses that they may not have finished) was 42%. The most common sites used were Codecademy, other unspecified tutorial sites, and YouTube and a small number of other specific sites.

Self-Directed Learning: Most students have engaged with any self-directed learning such as books or building projects, with the majority of them designing and developing their own projects, including games, websites, web applications, Arduino/Raspberry Pi projects, and general business applications. The time spent on these

projects varied significantly from a couple of hours to a couple of years with the average amount reported as approximately 40 h.

Other Sources of Experience: 30% of students indicated they had other sources of experience. These included post-second-level school courses that were not diplomas or degrees, previous third-level courses, and previous employment.

When examining the origins of prior experience, it was not unexpected, given the lack of formal inclusion of programming in Irish schools' curricula, that most students had gained their experience outside of school. Indeed, what was surprising was the extent and range of extra courses run by some schools both as part of their day-to-day curriculum and as extra short courses after school.

The low number of students who participated in clubs/groups compared to the proportion participating in school-based activities may seem surprising given the high profile of CoderDojo. However, this may be due to the relative infancy of this club, founded in 2011. This number might be expected to increase in the future in line with the increasing participation and growth of dojos in Ireland. However, it is clear that most non-online computing activities undertaken by students have been via schools.

Not unexpectedly, there is a relatively high number of students undertaking online courses, with Codecademy being the clear leader. The most popular languages being learned online are the web development scripting languages and Python.

Comparative International Perspective

There is a shortage of comparable national studies to place the Irish situation in full context, but some comparisons with international standards can be made. While prior knowledge of programming has generally not been the primary focus of research, some studies have investigated the effects of prior knowledge on such things as confidence levels (Macleod and Patterson 2012), problem-solving (Chen et al. 2007), and

gender balance (Wilson 2002) with previous programming experience often being cited as a predictor of programming success (Madigan et al. 2007; Hagan and Markham 2000). Interestingly, studies have shown that it is not prior knowledge of programming concepts alone but student self-efficacy, or their self-perception of their programming ability that has the strongest correlation with programming performance (Wilson 2001). Krpan et al.'s investigation into the correlation between students' success in introductory programming and mathematical courses included an analysis of student expectations and success rates in introductory programming courses at the Faculty of Science, University of Split, over 3 years. They found that early failure to understand basic programming concepts affects students' confidence and leads to increased drop-out rates (Krpan et al. 2015).

The background of Computer Science freshmen across two Finnish universities was investigated in 2011 and 2012 (Kinnunen et al. 2013). Differing levels of prior programming experience were found between the two institutions (62% and 38%), with the university with the more selective entrance criteria having the higher percentage. It is worth noting that between 43% and 63% of those with experience gained it through formal studies, an opportunity not currently available to most Irish undergraduates.

Data relating to the prior experience of over 900 students at the Eidgenössische Technische Hochschule (ETH) Zurich was collected over 7 years from 2003 and gathered from 77 students from University of York in 2008 (Pedroni et al. 2011). During this time Computer Science was an optional subject not universally available in either Switzerland or the UK at primary or second level, yet in both institutions, prior experience was high, running at a stable level of 78–84% across the 7 years. Interestingly, only 16–25% gained their experience at school, with most reporting self-study as the source.

Conclusion

Currently, roughly a third of freshman students studying computing in Ireland have had some

exposure to programming. To date, a lot of that experience is, necessarily, from self-directed and online study, but a surprising amount stems from schools which emerged as an important driver and facilitator for encouraging students into their first steps in programming. Nonschool clubs such as CoderDojo have grown in numbers and popularity since their foundation in 2011; however their effect in Ireland cannot be seen as yet in the third-level population. Together with the mooted introduction of programming at primary level and the introduction of Computer Science as a Leaving Certificate subject from September 2018, it is clear that the nature and extent of the prior programming experience of incoming undergraduates will be subject to enormous change over the coming decade.

When examining the profile of freshman students in any discipline, there is always diversity in terms of age, background, and general experience. This is a factor that third-level educators have always had to take into consideration when designing courses and choosing appropriate pedagogical approaches. With computer science primary degrees having the highest rate of non-progression in Ireland (varying between universities (15%) and institutes of technology (26%)), it is clearly important that the nature and impact of that previous experience be used as an evidence-base for decisions about future curriculum design and teaching practice, so that introductory courses be made more relevant and appealing to students consequently providing some contribution to student retention and competency levels.

Point of Departure

Problem- and project-based learning (PBL) was originally developed for collaboration between physically present students and teachers, but political decisions at many universities also require that collaboration, dialogues, and other PBL activities take place online. Teachers design learning situations with the intention of supporting the students. This study investigates how technology influenced the interaction between teachers and students and between students in two different online modules for master's students at Aalborg University, Denmark. The study aims to answer the research question “How do two online learning designs affect student engagement in the PBL online modules?” The empirical data were collected and analyzed using a netnographic approach. The study finds that concepts such as self-directed learning and active involvement may be perceived very differently from the students' and the teachers' perspective.

This study explores two online modules from two different human computer science education programs at Aalborg University: (1) “Proactive Review – A Design for Organizational Learning” from the Master in Information Technology and Learning (MIL) program and (2) “Development of Competences and Education in a Global

Perspective” from the IT, Learning, and Organizational Change (ILOO) program.

The pedagogical foundation of Aalborg University is the Aalborg Model (<http://www.en.aau.dk/about-aau/aalborg-model-problem-based-learning>), which entails problem-based and project-based learning (PBL). The curriculum of a course frames the problem definition and analysis. The students recognize a dilemma or a forked-road situation and formulate it as a question; this is the problem definition. They comprehend theories from the curriculum to understand the problem, and they utilize relevant methods to gather data. Their analysis is supposed to lead to suggested solutions to the problem (Kolbaek and Nortvig 2018). To stimulate thinking and learning, the students are required to work in groups (Dewey 1916); they complete the course by writing a project report, which is often defended orally in an exam.

PBL is the pedagogical expression of the theory that learning is context based and collaboratively constructed, in opposition to the theory that learning is context independent and individual. PBL requires certain behaviors and responsibilities of the students and the teachers. The students need to be curious (Dewey 1916), capable of identifying relevant research problems, and able to reflect on theories and on their experience from practice (Dewey 1916). They must possess the ability to study in groups and the willingness to take responsibility for running and finalizing projects in due time and with high quality (Tambouris et al. 2014; Kolbaek and Nortvig 2018). According to Tawfik and Lilly (2015), these may be difficult tasks for students who come to the university from other traditions. The Aalborg Model requires certain attitudes and behaviors of the teachers as well. For example, the teachers present fewer lectures and spend more time on supervising group work and scaffolding self-directed learning (Barrows 1996; Hmelo-Silver 2012). The teachers exert less control over the content because the students may define the literature, but the teachers still suggest relevant literature. Thus, the teachers need to be willing to change their role from that of a “boss” to that of a “facilitator” who supervises the students

in all phases of their project work and suggests content related to the course description and the problem formulated by the students (De Graaf and Kolmos 2003; Kolbaek and Nortvig 2018). The teacher leads the final assessment, which is the students’ oral defense of their project or the evaluation of a written report. Therefore, PBL requires students’ engagement independent of the teachers, as well as teachers who both support this independence and support the students in learning the curriculum in order to pass the exam.

This study explores the design *for* and the design *in* learning for two different master’s programs at Aalborg University. The design *for* learning is the learning design that the teacher creates and shares with the students, while the design *in* learning refers to the activities that actually take place when the learning design is in use (i.e., the students’ reactions to the design *for* learning) (Kolbaek and Nortvig 2018; Kress and Selander 2012).

In PBL, the students need to grasp theory according to the curriculum. This study digs into the design *for* and the design *in* learning theory as the foundation for the later project work. Both the design *for* and the design *in* learning are based online (Lajoie et al. 2014). Since the students participating in the study are completing their master’s degree, they possess a bachelor’s degree from various universities or university colleges and are familiar with the processes and responsibilities of PBL from their previous year at Aalborg University. The teachers encourage the students to become involved individually and in groups even though they are geographically dispersed, so the teachers create learning designs that include accessible technology. However, the intention and the response may not be equivalent, and the teachers may realize that the students respond unpredictably to the learning design. Consequently, the design *for* and the design *in* learning may be quite different (Kress and Selander 2012).

This study explores designs *for* learning in two online modules created by the teachers. The designs *in* learning, on the other hand, are the students’ reactions. The designs *for* learning

provide a dilemma: On the one hand, the teachers offer online lessons and scaffolds that are supposed to help the students understand important theories and find relevant resources; on the other hand, the teachers hand over the responsibility for the students' learning to the students.

A Netnographic Case Study

This study is based on online fieldwork in which the students' activities were observed by gathering data from the Internet, mainly from the following sources: Moodle (the learning management system at Aalborg University), Adobe Connect (the university's videoconference system), YouTube, and Google Groups. The study looks into the students' utilization of certain online resources provided by the teachers, as well as online communication between the students and between the teachers and students (Gill et al. 2005). As the collected data and the participant observation research originate in data shared on the Internet, this research practice may be classified as netnography (Kozinets 2015). In this method, the researchers are able to see the same screens and online interactions as the students, but the researchers have access to logged data to which the students do not have access (Jin et al. 2015). In general, netnographers do not know the informants personally but observe them at a "distance" on the Internet. In this case, the researcher was acquainted with the students because they had met face to face in previous lectures. The researcher in this study possesses a double role as a teacher first and as a researcher second. Bias was reduced by using only online data (Kozinets 2015), which prevented the researcher from influencing the students' behavior or feedback through her role as teacher.

The aim of this study is to understand differences between design for learning (the teachers' planning) and design in learning (the students' actions and reactions) when the design is accessible online and requires online participation. Consequently, it seems appropriate to look for traces that the students left behind online to investigate the students' actions and reactions, which

means that learning analytics could be an appropriate approach to this study (Duval and Verbert 2012).

According to Elias (2011, p. 5), learning analytics involves "(1) the development of new processes and tools aimed at improving learning and teaching for individual students and instructors, and (2) the integration of these tools and processes into the practice of teaching and learning." Learning analytics is a relatively new field of research, as "design for learning online" is relatively new compared to "design for learning face-to-face" (Merceron et al. 2016; Schwendimann et al. 2016). The Society of Learning Analytics defined learning analytics as "the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs" (Siemens and de Baker 2012, p. 252). The data may be gathered from the Internet or from mobile devices.

The point of learning analytics is to retrieve data that the teachers leave behind from designs to look into designs for learning, as well as to retrieve data that the students and teachers leave behind to study design in learning (Duval and Verbert 2012). The intention of learning analytics is to improve education (Siemens and de Baker 2012; Vatrappu et al. 2011). The data may identify differences between design for and design in learning that could support efforts to change the design for learning to improve student success (Elias 2011). Traditionally, data from design for learning stem from teachers' and students' evaluations gathered at the end of the lectures or at the end of the semester; in both cases, the data are self-reported, retrospective, and sometimes quite delayed. By contrast, learning analytics provides data gathered simultaneously with the activities without the interference of a researcher or teacher (Elias 2011).

Empirical Data from Aalborg University, Denmark

This section describes two different programs related to human computer science at Aalborg

University. Both programs consist of 120 ECTS (European Credit Transfer System) that should be completed within 2 years. This study looks into a module of 5 ECTS points from the MIL program and a module of 10 ECTS points from the ILOO program. The designs for learning cover a period of 6 or 7 weeks, during which the teachers present or suggest different themes that the students are supposed to work with (named “student activities”) on different IT platforms. The designs for learning are described in detail for the reader to understand how the teachers planned the students’ engagement in the online PBL modules. The students’ reactions - the design IN learning, is described in the section “Students’ Behavior”.

MIL: A Blended Learning Module

The MIL program is offered by the Faculty of Social Science. MIL requires 20 h of study per week for 2 years. The students must possess a bachelor’s degree and at least 2 years of work experience based on their university degree, including experience with IT development or implementation. MIL students work as professionals in private or public organizations and study part time.

MIL includes the module “Proactive Review – A Design for Organizational Learning,” herein referred to as “Proactive Review.” The aim of this module is to enable the students to learn about organizational learning from theory and practice by grasping organizational learning theories and by experimenting with a design for organizational learning (Kolbaek 2014). This module lasts for 7 weeks, with an accumulated student workload of 137.5 h.

This study looks into the design for and the design in learning for the years 2013 and 2015, during which the students were situated in Denmark and Norway, respectively. The first lecture took place face to face, whereas the rest of the course consisted of only online activities; thus, this module can be classified as “blended learning” (Garrison and Kanuka 2004). The final assessment of the students was based on two elements: participation and a report. The Proactive Review module was planned by one teacher

who was assisted by another teacher during the seminar and the online interactions. Table 1 gives an overview of the design for learning of the module for 2013 and 2015. Both years are included because the number of students was small – only 12 students in 2013 and 17 students in 2015. The design for learning is described in detail in Table 1.

The Proactive Review module started with a face-to-face introduction lasting 4.5 h, in which the students were introduced to theory about organizational learning and the specific design for organizational learning named Proactive Review (Kolbaek 2014). During this introduction, the students were asked to form groups of three to four that they would work with during the course. They were told to decide on the workplace in which to try out at least one Proactive Review. The students had tasks that they had to achieve as a group even though they were geographically dispersed with limited options for meeting face to face. In addition, the students had individual tasks to deliver online.

After the introduction, the students were occupied with other tasks for 5 weeks before they returned to this module. In the meantime, each group of students was supposed to practice at least one Proactive Review in a student’s workplace to get practical experience with this learning design for organizational learning. In week 2, the students had to read the theoretical texts in the curriculum suggested by the teacher, discuss a certain text in their group, and present it for the other groups as a brief text in a discussion forum (i.e., Google Groups in 2013 and Moodle in 2015). These texts served as an introduction to the individual online discussions in week 3, during which the students were obliged to deliver at least two comments on the other groups’ presentations. In week 4, the groups replied to the criticism received in the discussion forum in week 3 and concluded the discussion. At the end of week 4, the students and the teacher met in an Adobe Connect videoconference, and the groups presented their experiment with a Proactive Review and highlighted an obstacle or a problem they had faced. These issues became the starting point for

Problem-Based Learning Online, Table 1 The design for learning for the Proactive Review module

Time	Theme	Students' Activity	IT platform in 2013	IT platform in 2015
Week 1 4 h	Theoretical approach to Proactive Review - a desai for learning in organizations	Listen Roleplays Reflection Feedback Forming groups of 3–4 students	Face-to-face In Class	
Exercise period of x weeks	Practice approach to Proactive Review	Try out a Proactive Review in a students' work place	Face-to-face without teacher at a students' workplace	
Week 2	Theories of organizational learning	Reading and presenting theories	Google groups	Moodle Discussion Forum
Week 3	Theories of organizational learning	Individual reflection and criticizing another theory from the students' basic theory. Minimum 2 comments required	Google groups	Moodle Discussion Forum
Week 4	Theories of organizational learning	Reply to the criticism Conclusion on the discussion	Google Groups	Moodle Discussion Forum
	Proactive Review in practice	Present experience from the Proactive Review including at least one challenge	Adobe Connect video conference 105 min, Challenge described in Google Groups	Adobe Connect video conference. Question asked on in Moodle discussion forum
Week 5	Connecting organizational learning theories and practices of Proactive Review	Discuss the questions raised in the videoconference in week 4 by 3 comments at least	Google groups	Moodle Discussion Forum
Week 6	Connecting organizational learning theories and practices of Proactive Review	Conclude on the discussion and present suggestions for solutions by the end of the week	Google groups	Moodle Discussion Forum
Week 7	Synthesizing	Writing an essay on Proactive Review. 10 pages per group	LMS	LMS

the discussions in weeks 5 and 6, during which each student had to comment on at least two of the problems defined by the other groups. By the end of week 6, the group had to conclude the discussion, and the teacher's intention was for the group to formulate a suggested solution to the problem they had identified. In week 7, the groups were asked to write an essay of ten pages reflecting the learning processes and the results they had achieved from the module. The essays were to be delivered in the learning management system.

ILOO: An Online Module

The ILOO program is offered by the Faculty of Humanity. ILOO requires 37.5 h of study per week for 2 years. The students possess a professional bachelor's degree (e.g., teaching or nursing) or hold a bachelor's degree in the humanities or social sciences. Some of the students work part time. ILOO includes the online module "Development of Competences and Education in a Global Perspective," which lasts for 6 weeks. This includes 24 h of online training in which

the students' participation is optional, but they must pass the exam. During this module, some of the students exchange the lectures for internships in relevant organizations in Denmark or abroad; thus, the lectures are designed for online presence during work hours from 14:15 to 18:15 (CET, Central European Time Zone). The aim of this module is to enable the students to work with learning, training, and IT-related changes, including global perspectives in organizations. Eight teachers share the six 4-hour online lectures. The exam consists of an essay of 10–12 pages per student; if up to 4 students work together, each additional student extends the essay by 2–3 pages (Kolbaek and Nortvig 2018). In 2016, the teachers decided that the essay would be a literature review. To give the reader an overview, Table 2 shows the design for learning of the module “Development of Competences and Education in a Global Perspective” in 2016. These details are necessary to shed light on the huge difference between the students' engagement in the MIL module and in the ILOO module – the design in learning, which is presented in the section “Students' Behavior”.

In 2016, 72 students signed up for the module “Development of Competences and Education in a Global Perspective” which includes six themes that will be described in more detail below. The six themes are divided into the six lectures of the module. The students' activities vary from individual tasks such as individual exercises and listening to the teacher's presentation to online group work. Eight teachers share the six lectures between them. Sometimes three teachers are present during the online sessions, and sometimes only two teachers share the 4-h lectures. No teacher is present during all six lectures. The module utilizes mainly two online platforms: Moodle and Adobe Connect. Moodle provides information about the module, such as schedules, lesson plans, materials to read or watch, links to Adobe Connect videoconference rooms, Google Docs, and links to TED Talks and YouTube video recordings. All the lectures are provided through Adobe Connect videoconferences.

The first lecture is an introduction to the module; the three teachers in charge (BM, DK, and

RB) focus on different concepts of globalization and on the literature review as a genre. Seven teachers participate in all 4 h of this lecture. The students are supposed to prepare for the lecture by reading articles suggested by the teachers in Moodle. Students and teachers meet in a common videoconference room in Adobe Connect. After the introduction to the module, the teacher lectures on different concepts of globalization. At the end of the 4-h session, the students work in groups in Adobe Connect videoconference rooms to identify the topics and issues they want to learn more about during the module. They place their suggestions in a Google Doc. The students are then asked to do an individual literature search, and they place their results in another Google Doc. Finally, the teachers wrap up and close the session. Based on the schedule of the session, the teachers should speak for 195 min, and the students should do something other than listening for 45 min (breaks are not included).

The second lecture covers inclusion as a topic and is run by three teachers (AT, BM, and EK). As preparation for the lecture, the students are supposed to watch two videos (lasting 3.39 min and 22 min) and read two articles about the topic. After the teacher's introduction, the students are invited to reflect upon the term “globalization” as a continuation of the lecture from the week before. This is an individual task; the students write their reflections in a discussion forum in Moodle. A teacher lectures about inclusion and exclusion from a global perspective; this is followed by a discussion between the students in groups in videoconference rooms and the groups' presentations of their views in the common videoconference. Next, another teacher lectures on inclusion in Danish schools; at the end of the lecture, the students are invited to discuss this topic in a videoconference. According to the plan, the teachers are supposed to lecture for 95 min, and the students are supposed to participate in something other than listening for 145 min (breaks not included).

The third lecture is on culture and intercultural communication. As preparation for the lecture, the students are supposed to read three articles suggested by the teachers (BM, DK, and HH);

Problem-Based Learning Online, Table 2 Design for learning in the ILOO module “Development of Competences and Education in a Global Perspective”

Time	Theme	Students' Activity	Teachers	IT platforms
Week 1	Introduction to Concepts of globalization Literature review as a genre	Listen to teacher's presentation in videoconference Group discussions in Adobe Connect group rooms, to identify topics and issues they wanted to know more about during the module stated in a google doc Individual literature search Teachers' wrap up	BM DK RB	Videconferencein Adobe Connect Moodle Google docs

the students can watch two videos that cover two of the texts if they prefer Danish spoken videos over English written texts. After the teacher's introduction, the students are given time to watch the first 14-min video produced by one of the teachers. The video is followed by two exercises in which the groups exemplify the theory; half of the students work on one exercise, while the other half work on the other exercise. The groups collaborate in Adobe Connect videoconference rooms and present their results in a discussion forum in Moodle. The teacher comments on their results. The students are then asked to watch a teacher-produced video on an alternative conception of culture. The video lasts for 15 min and is followed by three exercises that the students do individually. The students put the answers in a Moodle discussion forum, and the teacher comments on their contributions before she wraps up and encourages the students to write their feedback on the lecture in Moodle. According to the

plan, the teacher should lecture for 90 min (including the two videos), and the students should be active in tasks other than listening/watching for 150 min.

The fourth lecture, presented by two teachers (AN and CW), is on IT and the understanding of technology in global education. As preparation for the lecture, the students are supposed to read two articles and prepare a 5-min presentation on a relevant article. The students try out the website www.learningdesigner.org to plan an online lecture. After the teachers' introduction, the students are divided into groups that meet in Adobe Connect videoconference rooms, where they present the article to fellow students. The group identifies challenges in online learning design according to the presentations. Everybody meets in the common videoconference, where the teachers conclude the exercise before the students go back to their groups to create a learning design for online teaching that addresses the challenge they

identified in the first exercise. Later, every group tries out their design on another group and receives feedback. Finally, the students share their reflections on this lecture in the common videoconference. According to the schedule, the teachers are supposed to talk for 95 min, whereas the students are supposed to interact with each other for 145 min.

The fifth lecture addresses the topic of citizenship and fieldwork in online settings and is presented by two teachers (AN and BM). The students are supposed to prepare for this lecture by watching a 10-min video accessible via the university library and by reading two articles. After a brief introduction in the common videoconference, the students are asked to watch a 13-min video produced by one of the teachers before they meet in groups in Adobe Connect videoconference rooms. The groups discuss the term “citizenship” and formulate two questions, which they place in a Moodle discussion forum. Individually, the students read, choose, and reply to two questions asked by another group. The subject then changes to netnography, and the students are asked to watch a 19-min teacher-produced video. Next, the students are asked to contribute to a blog (discussion forum in Moodle). Finally, the teacher concludes the videoconference before wrapping up. According to the plan, the teachers are supposed to talk for 105 min, whereas the students are supposed to do something other than listening to the teacher for 120 min.

The sixth and final lecture in this module includes the topics of participatory culture and makerspace, which are presented by two teachers (DK and HH). As preparation for this lecture, the students are supposed to watch a 20-min teacher-produced video about makerspaces; they then reply to two questions asked at the end of the video and place the answers in a Google Doc. The students are also asked to read three articles. The Google Doc serves as a way for the students to brainstorm on their understanding of and approach to makerspaces, which they discuss from the beginning of the lecture in the common videoconference. The students are then asked to watch another 22-min teacher-produced video on

makerspaces. The students and teachers meet again in the common videoconference, and the students are divided into groups that apply the theory to different makerspaces and prepare a presentation. As this is the final lecture in the module, the students are invited to give thorough feedback in a Google Doc on an individual and anonymous basis. The next activity is the students’ presentations. The students are split into two groups that go to two Adobe Connect videoconference rooms with a teacher who facilitates the session. The students then return to an individual activity, namely, watching a 14-min teacher-produced video presentation on literature reviews. They then suggest “search words” for a literature review and place them in a Google Doc. According to the plan, the students should listen to the teachers for 55 min and do other activities for 185 min.

Students’ Behavior

This section explores the students’ reactions to the design for learning being the design in learning. More specifically, the analysis looks into how the two learning designs affected student engagement in the modules. MIL had only 2 teachers, 12 assigned students in 2013, and 17 assigned students in 2015, whereas ILOO had 8 teachers and 72 assigned students in 2016. The expected workload for the students was 20 h a week for the MIL students and 37.5 h a week for the ILOO students. The MIL students met face to face for 4 h in the introduction, while the ILOO students met only online during the module. MIL included only one theme, namely, Proactive Review, while ILOO included six different themes. Table 11 in Appendix A shows the students’ activities week by week according to the data gathered from the online sources. Data from Table 11 are presented below by theme.

Preparation: Heroes and Villains

This section looks into the students’ preparation for attending the online classes (Table 3).

To gain experience with a design for organizational learning, 100% of the MIL students in both

years prepared and practiced a Proactive Review in a student's workplace and identified the challenges involved. They had to engage and make it happen without further teacher support; since they were geographically dispersed, they prepared online on IT platforms of their choice. The MIL students also had to read texts as preparation for their group work. The data show that all the students in both years presented the theories as required (Table 3).

To understand the theme of the day, the ILOO students were supposed to read texts and/or watch video presentations before attending the lectures in Adobe Connect videoconferences. The data do not show the extent to which the students actually read the texts, but the log uncovers that the first video in week 3 had 61 clicks, and in average the video was watched 68%. The second video in

week 3 had only 53 clicks and was viewed 60% in average. The first video in week 5 had only 32 clicks, and in average these clicks made the watchers view only 39% of the video. In week 6 the video was clicked upon 32 times, and in average it was watched 62%. The few clicks and the small portion of videos viewed show that the students hardly watched the video presentations (Table 4).

The teachers had handed over the responsibility for learning to the students, and the MIL students embraced this responsibility both for reading texts and for practicing a design for organizational learning in "real life." By contrast, the ILOO students did not take responsibility for watching the videos in full; unfortunately the data do not show the extent to which they read the texts.

Videoconferences: Lusting or Lurking, Listening, and Leaving

The lectures were placed in Adobe Connect videoconferences to ensure accessibility for all students despite their geographical distance to the university and to fellow students (Table 5).

The MIL students only participated in a single videoconference lasting for 105 min. All students participated from beginning to end (in both years), presenting and discussing their experience with the design for organizational learning. It seems as if the MIL students “lusted” to collaborate in the videoconference (Table 5).

Only 59% of the ILOO students participated in the first of six videoconferences; this number declined over the 6 weeks to 31%. With each 4-h online lecture, student participation declined, becoming worse over the 6 weeks. In the first week, 50 students attended the introduction, but only 21 students (42%) participated in the wrap up. In the second week, 41 students (51%) attended the introduction, but only 18 students made it to the wrap up. In the third week, 40 students (56%) followed the start of the lecture, but only 11 students completed it. In the fourth week, 22 students (31%) connected to the videoconference, but the data do not show how many stayed up to the end. In the fifth week, 26 students

(36%) attended the introduction, but only 7 students made it to the end. In the sixth week, 22 students (31%) participated in the introduction, and 9 students kept on until the wrap up. The ILOO students seemed to mainly lurk in the videoconferences with very poor engagement, so they missed the opportunity to learn from the teacher or to collaborate with fellow students (Wilkerson 2016). The students were familiar with the technology and with each other from previous semesters, so a lack of technological knowledge or unfamiliarity with the other participants could not be the reasons for not showing up or leaving early (Table 6).

Online Group Work: Barking Up the Wrong (or Right) Tree

PBL is founded on group work; thus, group work is an integrated part of the design for learning in both MIL and ILOO. The group work is supposed to enhance engagement, learning, and reflection (Dewey 1910; Kolmos et al. 2004) (Table 7).

In both years, all MIL students attended the group work. In the first year, the 12 students decided to form 3 groups instead of 4 because they wanted to engage with more fellow students in the group work. The MIL students worked in groups according to the schedule and IT platforms

Source: Table 11, Appendix

they had decided on, and the teacher was only involved occasionally. These groups decided on the workplace in which the design for organizational learning should be tested. They tested and reflected upon the experience in the groups, and the groups presented their experience in a video-conference. The groups also presented a relevant theory in a discussion forum in Moodle, which other students criticized. The MIL students engaged in the group work independently of the teacher, as the group members met online to solve the tasks required in the module. The students interacted with the teacher when convenient, when they wanted to clarify the requirements, or when they were in doubt. We may say that the teacher “delivered on demand.” (Table 7).

The teachers had prepared 11 groups for the ILOO students, but the first lecture included 10 groups due to the declining number of attending students. The number of participating students varied over the weeks; the number of groups declined to three in week 2, increased to five in week 3, disappeared in week 4, increased to six in week 5, and decreased to five in week 6. Looking into student engagement within the group work, it appears that out of the ten groups, only eight groups contributed to the Google Doc in week 1. In week 2, only eight students delivered nine comments in the Google Doc; the data indicate that the comments were written on an individual basis. In week 3, all five groups presented their group work in a Moodle discussion forum, but in week 4, no students engaged in

group work, and only one comment was delivered by a single student. In week 5, the 6 groups were supposed to deliver 12 questions to be answered by other groups, but the 6 groups only delivered 7 questions. In week 6, only three groups out of five presented an example of a makerspace. The students were supposed to do the group work throughout the online lectures, and the teachers were available for questions or comments. But the students did not utilize the teachers even though they were accessible, which may indicate that the students engaged only briefly in the module. Although the teachers were present throughout the online group work, the students did not interact with them and did not take the opportunity to get help to achieve the requirements. The design for learning at ILOO included online group work during the online class and excluded group work between classes. We may say that the teachers “delivered on time” in opposition to the design for learning at MIL that excluded online group work during the video conference and included online group work before and after classes. The fact that the ILOO students engaged only briefly indicates a lack of interest despite the teachers' efforts to make an engaging design for learning. Perhaps the ILOO students were trying to reveal that the teachers were barking up the wrong tree. The lack of engagement and the lack of feedback gave the clue “something must be changed,” but did not indicate what “something” should be (Table 8).

Individual Contributions: Why Bother?

The students were asked to reflect upon theories and personal experience to enhance their learning (Table 9).

The MIL students engaged in individual contributions in weeks 3 and 5. They engaged in the discussion in both years by delivering more comments on average than required, as indicated by the 150% and 154% participation rates in 2013 and 2015, respectively (Table 9).

The ILOO students’ level of engagement in individual contributions varied over the 6 weeks. In the first week, no data was available. The percentage of attending students who contributed individually to the discussion forum as required was 22% in week 2, 20% in week 3, 77% in week 4, 38% in week 5, and 50% in week 6. The ILOO students did not seem to feel obliged to contribute their reflections to the collaboration in the discussion forums, which prevented them from learning by putting their experiences, concerns, or doubts

into words. This hindered them from learning from each other (Table 10).

Video Presentation: Snooping and Sneaking

The video presentations of content should make it easier for the students to grasp theories or understand terms. Some of the video presentations were produced by TED Talks or other professional providers, while others were produced by the teachers. The videos were available before, during, and after the lectures. The MIL students had no video presentations in the curriculum.

The ILOO students were expected to watch eight videos over the 6 weeks. In weeks 3, 5, and 6, the design for learning allotted time for watching the videos during the lectures, but most of the students ignored this resource, and very few students watched a video from beginning to end (Table 5). The statistics indicate that the videos were mainly watched during the lectures, and no videos were watched all the way through after the

lecture. Students who did not attend the lectures did not watch the videos either. The first video in week 3 had 61 clicks, which suggests that 85% of the students had accessed the video. But the teachers also took the opportunity to watch the video, and an average of only 68% of the video was watched; this means that although a number of people saw the video all the way through, a substantial number only watched portions of it. The second video in week 3 had 53 clicks, and only 60% of it was viewed, so very few viewers saw all of it. In week 5, the first video had 31 views, which is more than one click per attending student. On average, 39% of the video was watched, so only a few minutes were shown to the 31 viewers. The second video had 29 clicks, which is more than one click per attending student. However, only bits and pieces were watched, as an average of just 53% of the video was viewed. In week 6, the students were supposed to watch the video as preparation for the lecture. Twenty-two students attended this lecture, and the video had 22 clicks, but an average of only 32% of it was viewed. This means that some students just clicked on the video and watched no more than a few minutes. The design for learning allowed the students to watch the second video during the lecture; the video got 32 clicks, and an average of 62% of it was viewed. Some students may have watched most of or even the full video.

Conclusion

This entry explored the research question “How do two online learning designs affect student engagement in the PBL online modules?” The analysis raises the question of why students in

one program engage intensively in the module while students in another program hardly engage in the module at all. The latter caused frustration among the teachers, who looked for explanations in order to change the design for learning and engage the students in the future.

Did the technology affect student engagement negatively? The MIL students experimented with Google Groups in 2013, and the “new” technology did not seem to scare them away. In 2015, the MIL students utilized Moodle, which they knew from the previous semester. The technology did not seem to affect MIL student engagement negatively. The ILOO students were familiar with Moodle from previous semesters, but the videoconference was new to them. Utterances in the video recordings make it clear that the students found it hard to switch between Moodle and the videoconference and hard to access the group videoconference rooms. This may be a reason for dropping out (Amichai-Hamburger et al. 2016). Another reason may be that the technology makes it easy to access the lecture and seemingly be present even though the student has left the room or is mentally absent—they can sneak out without getting disapproving looks from the teacher.

The duration of the videoconferences may affect student engagement (Ravitz and Blazeovski 2014). The MIL students met only once in a videoconference for 105 min, while the ILOO students met every week for 240 min. The MIL students were engaged from the beginning to the end of the videoconference, but only a few of the ILOO students stayed for the 4-h lecture – if they showed up at all. A 4-h videoconference seems to be too long even if the students are invited to interact with each other in smaller groups or individually in

discussion forums for half the time (in weeks 1 and 3) or more than half the time (in weeks 4–6).

The formal requirements may also affect student engagement. The required student competences differed between the programs. The MIL students had already worked full time for at least 2 years, they studied part time while working in full-time jobs, and they were more than 30 years old. The ILOO students were young, full-time students. The MIL students needed to be highly motivated to take up this huge extra task of studying, whereas the ILOO students did not study as an extra task but as their “full-time work”; perhaps their motivation was not so clear to them. The requirements of participation also differed. The MIL students could pass the exam by participating in the activities and writing a short essay, or they could deliver a bigger report if they did not engage in the training. The ILOO students participated in the online lectures on a “voluntary” basis, as these lectures could be perceived as resources the students could choose when convenient. In the end, they had to deliver a literature review independently of their participation in the lectures. These different requirements for the two modules may have had a positive impact on the MIL students’ engagement, whereas the ILOO students could pick and choose, and they chose to engage quite superficially.

Teachers’ involvement is another factor that may affect student engagement. Only two teachers maintained the MIL module, whereas eight teachers were involved in the ILOO module. The two MIL teachers interacted with the students several times a week in the discussion forums. The small number of students enabled the teachers to know each student by name; this fact and the continuous interaction seem to have enhanced the personal relations between teachers and students, which supported student engagement over the 7 weeks. The ILOO students met the teachers only online and just once or twice for 4 h; in between the weekly lectures, they were on their own. The lack of continuity combined with the high number of students prevented the teachers from getting acquainted with the students. The teachers stayed at a distance, and the students never overcame the screen to develop personal ties with the teachers. This lack of personal

relations between teachers and students may have had a negative impact on student engagement.

It is not fair to call the MIL students “heroes” and the ILOO students “villains,” as the preconditions for their studies are so different, but it expresses the teachers’ emotions. The MIL students are older and possibly more self-aware, and they have the opportunity to form personal ties with the teachers, which is more than difficult for the ILOO students. In addition, the ILOO students’ participation did not have an influence on the final requirements of the assessment, whereas the MIL students’ participation was mandatory – unless they preferred to deliver an extended final report.

The teachers’ accessibility may also influence the students’ engagement. The teacher “delivered on demand” for the MIL students, so they interacted with the teacher when they felt the need to during their group work, which took place independently of the teacher’s presence. The teacher “delivered on time” during the ILOO online lectures, and the ILOO students were highly reluctant to interact with the teacher; the data do not provide reasons for this, but perhaps they had snuck out of the online lecture.

PBL requires students’ engagement independently of the teachers, as well as teachers who both support this independence and support the students in learning the curriculum in order to pass the exam. The data showed that teachers’ “delivery on demand” supported the students’ independence to a higher extent than “delivery on time.” Besides, the study shows that the independence enhances the students’ engagement in class and outside class, as the MIL students engaged to a higher extent than the ILOO students.

The students’ engagement affects the result. Only one MIL student dropped out, consequently 90% of the students passed the exam in 2013, and 100% passed the exam in 2015. Only 61 out of the 71 ILOO students signed up for the exam, and 59 ILOO students passed, which is 82% of the ILOO students. Unfortunately the ILOO students did not comment the lack of engagement in any feedback, which the teachers will miss when they change the design for learning to improve student success.

The data identified huge differences between design for and design in learning. The study finds that the teachers and the MIL students seem to share the perception of self-directed learning and active involvement, whereas the teachers and the ILOO students seem to perceive these concepts quite differently.

Problem-Solving in Computer Science, Learning from a Gifted Peer

Bertold Kujath and Andreas Schwill
Institute of Computer Science, University of
Potsdam, Potsdam, Germany

Introduction

How does the problem-solving process of high performers differ from that of low performers and what are the different strategies used in the work phase? These questions were examined at the beginning of the video project in a *think-aloud* study. For this comparative study, two groups of eight participants each were asked to solve typical problems of computer science (CS) in individual sessions and to verbalize their thoughts aloud. The first group, which will be referred to as the group of high performers in the following, was composed of the winners of the annual national competitions in computer science of 2 years. The participants were between 17 and 19 years old. For all of the eight participants, an IQ higher than 130 was determined, which is considered as the threshold to psychometric intellectual giftedness (Waldmann and Weinert 1990). The participants of the contrast group, which will be referred to as the group of low performers in the following, were recruited from students studying CS at the University of Potsdam. They were aged 22–30 years, showed predominantly medium to low academic performance in subjects with a theoretical-formal focus, and described themselves as weak problem-solvers in a survey.

The verbalizations as well as the sketches produced by the test persons while solving the task were recorded by video camera. Subsequently the data were evaluated using qualitative content

analysis as described by Mayring (2014). A detailed description of the test procedure and the evaluation method can be found in Kujath (2006, 2007). Based on the results of a graph coloring problem used in the study, fundamental differences of high and low performers' approaches in problem-solving will be discussed in part A of this paper. The graph coloring problem is outlined in Kujath (2008) including an extensive discussion of the solution.

Considering the significantly different approaches in the two comparison groups and the noticeably higher success rate among the high performers, the next logical step was to identify the more efficient problem-solving methods in order to impart them to the weak problem-solvers with the help of didactic concepts. As for the question of teaching aid, the form of an educational video was chosen since it gained support in the educational community recently not least because of its easy distribution possibilities over the Internet. Despite the known weaknesses of the medium due to its one-dimensionality, the educational video offers an added didactic value through high vividness and the possibility to present complex procedures dynamically (Kittelberger and Freisleben 1994). Paivio (1986) and Berk (2009) see benefits of this audiovisual medium from the perspective of the psychology of learning as well, as contents of instruction can simultaneously be presented in different forms of presentation (picture vs. text), which increases the attention and learning performance. An educational video can offer an even greater learning effect, if it is not used in isolation, but in the context of a suitable teaching concept (Sailer and Figas 2015), e.g., as an introductory learning tool to a new subject. The resulting educational video shows a fictional high performer working on a comparatively difficult graph coloring problem. The video is available in a German (Kujath 2011a) and an English version (Kujath 2011b). Just as it was done in the study, the high performer speaks out loud his considerations; his continuously created solution sketches on paper are shown in top view and are clarified in sections with animated movie sequences and verbal explanations. The video covers the computational problem-solving techniques "trees" and "recursion," and its content is primarily dedicated to those CS

students who are aware of these methods but are unable to apply them in the context of problem-solving. In part B of this paper, the didactic concept of the video will be outlined, and the filmic implementation of the high performers' strategies will be explained in detail.

Finally, in another comparative study, the learning effectiveness of the final educational video about computational problem-solving strategies was analyzed. We examined whether the didactically prepared findings of the *think-aloud* study actually evoke a learning effect for weak problem-solvers and, if so, to what extent. For this purpose, two separate groups of weak problem-solvers were formed, each consisting of low-skilled first semester CS students of the University of Potsdam. The participants of both groups were asked to solve a graph coloring problem similar to the one shown in the video under the conditions of a written examination: one group after watching the video and the other group without seeing it in advance. The experimental procedure and the results are discussed in part C of this paper.

Results of the *Think-Aloud* Study

The difference between the behavior of high- and low-performing problem-solvers became particularly obvious with a 3-coloring problem (see Appendix). Generally speaking, the problem-solving process of the high performers could be clearly divided into *comprehension* and *analysis* of the problem, followed by the *solution* and its *evaluation* – the phases commonly described in the relevant literature. Already in the first phase, the comprehension of the task, high performers showed notable strengths. Usually, they understood the task completely and correctly already after it was read out by the examiner only once and turned to the task immediately after the starting signal. Consequently, we have no findings about the high performers' techniques of problem and text comprehension due to the lack of verbalizations during this phase. Many of the low-performing problem-solvers started their process by asking the examiner comprehension questions without first looking for an explanation on

their own. Furthermore, misinterpretations of the task among some of the participants in the group of low performers were not corrected during the entire work process and consequently led to wrong results. Two participants of this group did not understand the task at all.

The first activities shown by the high performers aimed at a detailed analysis of the conditions of the task. In this group, key findings established in this phase were applied exceedingly efficient and purposeful later in the process. This enabled the test persons to construct the answer to the question of the maximum number of color combinations instead of searching for it by unspecific trial of every possible combination. Those key findings were missing to the low performers, who started without exception working on the solution immediately and without a prior problem analysis.

Evident differences were also found in the approaches during the concrete process of problem-solving. Here, low performers were predominantly enactive, trying out all possible color

combinations more or less purposefully, in order to generate generalized statements about the solution from the set of noted color sequences. Even though some solutions were at least partly correct, this approach of problem-solving required intensive writing and was time-consuming as well and thereby also more prone to random mistakes. In the high performers' problem-solving processes, in contrast, distinct fundamental ideas of computer science as described, for example, in Schubert and Schwill (2004) were visible. In the specific context, these were tree structures and recursion, which in combination with the key findings of the analysis phase were purposefully applied.

The perspective on the task was not static, as with the low performers, who considered multiple individual cases, but can be regarded as abstract and dynamic, which is evident in the way they investigated the peculiarities of coloring a rectangle from left to right. As a consequence, the group of high performers mostly showed much shorter and, in addition to that, error-free problem-solving processes. As an example, Fig. 1 shows the original

Problem-Solving in Computer Science, Learning from a Gifted Peer, Fig. 1 Worksheets of participants. Left: participant T10 (high performer group). Right: participant T53 (contrast group)

sketches of two participants, which are typical for the different approaches of the two groups. The left image shows the sole worksheet used by the high-performer T10, clearly indicating the CS methods of tree structures and recursion. The right image shows one out of three worksheets used by participant T53 from the group of low performers. The only apparent strategy here was the creation of complex and ever-growing tables with all possible color combinations.

After the completion of the task, the participants were interrogated about their course of actions and thoughts during their work. All of them were aware of methods specific to computer science like tree structures and recursion in order to solve problems. However, most of the subjects from the low-performer group did not even consider using any of them. Two subjects from that group expressed thoughts like “I shortly thought of it, but then dismissed the idea.” They claimed that the fundamental ideas of CS had been imparted to them merely in theory and without any problem-related examples. Furthermore, many of the low performers tried to avoid dealing with CS tasks as much as possible or gave up very early in the process. This was obvious due to expressions in the interviews like “I know I usually don’t find the right answer, so I don’t even start trying.” The following table outlines the differences between the approaches of the high and low performers, which have been identified through the verbal protocols (Table 1).

Concept of an Instructional Video for Teaching Informatic Problem-Solving Strategies of High Performers

Motivation

Many weak problem-solvers avoid the confrontation with CS problems because of the reasons stated above resulting in tedious working time and the anticipated failure. However, working on such problems is indeed what creates a deeper understanding of the matter and leads to a growing fundus of schemata on how to solve problems which results in the ability to explore even more complex contexts (Fuchs 2006; Friege 2001). The didactic and multimedia preparation of the study’s

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 1 Different phenomena of the participants during the work process

High performer	Low performer
Quick comprehension of the problem	Often immediate questions to the examiner
Intensive analysis of the problem ⇒ focused use of key findings	No analysis of the problem ⇒ key findings either found by chance or disregarded
Clear division into subproblems	Rare division into subproblems
High level of abstraction, concretion as needed	Enactive approach, only concrete data
Strong idea about the fundamental ideas of computer science	Unspecific approaches through trial and error
Question: What happens at the transition from n to $n + 1$?	Question: How many possibilities are there with $n = 1, 2, 3$, etc.

findings is intended to close the obvious gap between teaching of declarative contents in the lectures, where the fundamental ideas are mostly presented without any concrete examples, and training of procedural skills. It is intended to help learners discover how to use the principles of the fundamental ideas of computer science to solve problem-related contexts. With the help of an audiovisual representation of the high-skilled problem-solvers’ approaches – that is, by teaching the “tricks of high performers” with a video – the learner without practical experience is supposed to see how the theory of the lecture can be put into practice. The strategies of the high performers shown in the video point out typical beginners’ mistakes and their problems, such as deficient comprehension of the problem, subject-unrelated approaches, or the trial-and-error method. Learners are supposed to achieve a general ability to use common CS specific problem-solving techniques to effectively deal with exemplary tasks.

Justification for the Choice of Using the Medium “Film”

There is a variety of views on the medium “instructional video” in literature. Kittelberger and Freisleben (1994), for example, refer to the comparatively high familiarity of the medium “film.” However, this entails the danger of watching the movie or a short clip rather as an

entertaining medium and missing the educational message behind it. Lippert (1987), on the other hand, sees a big advantage in the medium “film,” since the audience is more likely to decode the message of the movie due to a higher amount of experience in film-visual perception. Another point of criticism is the linearity of a movie and the lack of feedback and alternative sequences. On the other hand, movies have a high density of information as well as a high vividness through visualizations and dynamic picture sequences (higher perceptive input). This leads to the possibility to teach even complex contexts with just a few means of expression, which otherwise can be difficult to be explained and less vivid. Image, sound, and sequences of actions address more perceptual categories, which leads to an additional didactic value of the medium “film” (Kittelberger and Freisleben 1994). Additionally, Paivio (1971) reports an increase of the viewer’s memorizing performance of learned material, if relevant points are presented with verbal as well as visual information. If used appropriately, a movie creates a realistic environment, which increases the amount of involvement and the possibility of identification and thereby also increases the learning effect of the viewers.

The cinematic presentation of results from an *Aloud* session is outlined in Heller et al. (1993). Projects in the USA are portrayed, in which the original tapes of the sessions with highflyers or experts are shown to low performers. In some sessions, the high performers worked live and *aloud* in front of a group of low performers. However, from the authors’ point of view, this approach seems problematic. Firstly, experience shows that the verbalizations are hard to understand at times. The voice of the participants is often too quiet, the formulations sometimes just consist of small clauses, or the whole thinking process is discarded by the problem-solver. Secondly, due to missing clarifications, the observer is left alone with the entire process. Consequently, the concept presented here follows an alternative approach. First of all, the verbalizations of the participants were linguistically smoothed. Afterward, strategies and typical elements commonly used by the high performers were chosen. Finally,

everything was put together into an optimized problem-solving process. The high performers’ sketches were processed in a similar way. The resulting edited process was acted out in the style of a *think-aloud* session by a professional actor in proper voice and audio quality. The individual activities were contrasted with animated comments in the fashion of an instructional video. The aim is to enable the viewer to reach a complete understanding and a continuous comprehension of the presented problem-solving steps. Educational experts recently discussed a further advantage of educational videos. Thanks to the possibility of the dissemination via the Internet, they can contribute to time and location independent learning and facilitate to review the material again later at home. Consequently, the medium “film” offers an additional possibility of visualization and represents an appropriate and valuable course material. However, the authors argue that the medium should not be used isolated but always as an additional tool in an educational framework.

Concept Description

Definition of the Target Groups

The intended audience of the video are those students of computer science who are aware of the theoretical concepts like tree structures and recursion, but lack the corresponding procedural abilities and experiences to use these instruments. This concerns students who recently learned these structures as well as those students who have been aware of them for quite a long time but have not been able to apply them in a problem-solving context. Also included in the target group are students of the secondary education level who participate in school IT classes and fulfill the same knowledge requirements.

Differentiation, Restrictions, and Didactic Reduction

The original task consisted of four subtasks: finding a formula for the amount of color combinations for the upper row and in compliance with the combinations below for each maximum and minimum case. The final video was reduced to only finding the

maximum case. For solving the maximum case, tree structures and recursions are needed. The comparatively easier minimum case is presented at the end of the video as a task for the audience to practice and as a means of achievement test.

It is not the aim of this video to convey the principles and effects of the fundamental ideas of CS. Hence, an explanation of the presented principles is omitted deliberately. They are assumed to be familiar and understood. Furthermore, the video does not intend to focus on every single aspect and fact of the high performers' approaches. Some of the problem-solving processes of the high-performer group were highly individual and also very effective, but they are not appropriate to teach to novices. From all eight approaches, just those that represented a clear problem-solving structure and involved the principles of the fundamental ideas were included in the video. To be precise, the video contains approaches from the participants T10, T31, and T38 and focuses on "problem analysis," "problem-solving process," and "solution evaluation." Since the high performers did not comment the comprehension of the problem or the text, the video begins with analyzing the problem.

The video was didactically reduced especially at one section of the high performer's approaches in order to keep the complexity low. The derivation of the recursion formula, which is used to calculate the maximum amount of color combinations of the length n of the rectangle, was replaced by two mathematical conversions. In the problem-solving approach chosen for the video, two high performers developed the recursive base equations shown in Kujath (2008) by means of a tree structure. Afterward, the high performers set up a numerical series from the respective numbers of color combinations depending on the length n of the rectangle. These were then either calculated by counting the nodes of the tree structure, or they were calculated using one of their equations. Finally, the series of numbers made the high performers realize the underlying Fibonacci sequence. This process of inductive reasoning is needed to develop the generating scheme of the sequence of numbers. However, in the current example, it requires knowledge of the Fibonacci

sequence, yet for many low-performer students, this is not the case. Since the needed formula can also be developed by mathematical conversion of the recursive base equations, the video deviates from the actual approach of the high performers in this section. Thus, the formula can be found without any explicit knowledge about the Fibonacci numbers.

The Movie Script

Background Story From a media-didactic point of view, cinematic actions in which teaching content is embedded support the comprehension if used adequately. The educational core, which is presented below, is embedded in a story which presents the character of Tom – a high performer. The opening of the video, which is set up to look like a television report, starts by showing a group of students working on an exam task during a lecture. A short comment roughly explains the task, whereas an explicit explanation is put at the beginning of the educational part of the video. Afterward, some students are interviewed individually about their experiences with the given task. The students describe similar problems like the ones of the participants of the low-performer group. This aims at sensitizing the viewers to the topic and reconsidering their own problem-solving processes. Figure 2 shows four so-called scribbles in which scenes of the story are illustrated. Such scribbles help to visualize film scenes in the early planning stages. Typically, they are reduced to hand drawings with a pen just showing essential points of the scene with stick figures (Mair 2005).

Educational Core With Tom starting to solve the problem, the actual didactic part is initiated. The high performers' videos were analyzed with the focus in mind of finding distinctive and didactic helpful problem-solving activities. Afterward, those strategies were put together to one fictive, coherent, and optimized problem-solving process, which is depicted as a real situation in the video. One of the most important parts of the concept is to simulate the authentic work on the task. The viewer is supposed to be under the impression of sitting

Problem-Solving in Computer Science, Learning from a Gifted Peer, Fig. 2 Scene scribbles of the story. Group of contrast participants, top-left; explanation of the

problem by the investigator, top-right; individual interview after the exam, bottom-left; welcoming of the high-performer Tom in the lab, bottom right

right next to the high performer solving the problem.

The educational part is divided in two levels. On the first level, there is the specific problem-solving process showing Tom trying to find an answer to the given task. On the other level, an abstract comment level, Tom's preceding solving techniques are shown and explained. Both levels are shown alternately during the entire movie. At first, the task is presented. Afterward, the problem-solving process of Tom is shown on the problem-solving level. Just as done in the study, only his sketches and his corresponding verbalizations are shown. The original phrases were taken word-by-word as far as possible and smoothened and paraphrased if required. Additionally, verbalization from three different successful high

performers was put together coherently to create a comprehensive and complete overview of the succeeding problem-solving activities. If there were synonyms used to describe the same object – like the 1×1 -square was denoted by the subjects as “square,” “box,” or “field” – those terms have been linguistically harmonized.

At particular points, the display of the problem-solving level is interrupted to summarize preceding activities and explain them on the commentary level. All comments were written according to the recommendations for text comprehension given in Mair (2005) and Märtin (2005). In order to indicate the different levels, a clearly different layout and a shift between the speakers was used. During the animation, relevant parts of the original sketches as well as significant

formulations of the fictive problem were incorporated with the original voice. Afterward, the simulated problem-solving process continues at the problem-solving level. The dual presentation of the same content from two different perspectives – on the one hand the verbalizations during the process by Tom and on the other hand the animated explanation – ensures the necessary redundancies of the shown content. This supports the comprehension and the viewer's willingness to learn (Kittelberger and Freisleben 1994).

The Sequence in Detail In the following, the individual sections of the educational part are shortly introduced. A summarizing representation can be found in Table 2.

Explanation of the Problem For the reasons stated above, there are no verbal comments of the high performers about their problem and text comprehension techniques. Hence, the first module of the educational part provides an explicit explanation of the task of solving for the maximum case. It is important to make the viewers completely understand the problem task, since

otherwise they will not be able to follow the subsequent steps. This is accomplished by two things. First, little prior knowledge is assumed during the explanation. Second, the complex correlations are presented in simple consecutive animated graphics, which build on each other. The solution will not be provided, so that the viewer is able to create his own chain of thoughts during the video.

Analysis of the Problem The first activities of Tom shown in the material are supposed to provide an intensive analysis of the problem, in which the viewers can participate through Tom's verbalized line of thoughts. This essential phase of the problem-solving process was omitted completely by the low performers of the study. Tom considers the problem as a sequential coloring process and starts to draw a sketch which corresponds to the original papers of participant T38 of the study. Just like this participant, he scrutinizes how many possibilities exist to color the second upper box from the left. At the end of this phase, Tom comes up with the key finding of the diagonal relationship discussed in Kujath (2008).

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 2 Summary of the single stages in the educational part of the movie

Phase	Activities	Minutes
PC	T: Completed by the beginning of the educational part	0
	C: Full explanation of the task of finding the maximum case	3:00
PA	T: Preparation of a sketch to analyze the problem – considering the problem as a coloring process – recognition of significance of the color of the diagonally arranged squares – conclusion for next steps	2:30
	C: Animated original sketch of Tom – indication of importance of intensive problem analysis – explanation of key finding and its value for the problem	3:00
PSC	T: Successive development of a tree structure using the key finding – construction of the lower color sequence sought for – statement about the first part of the solution	5:00
	C: Transformation of entire tree sketch into an animated graphic – reference to the tree structure as an informatic problem-solving tool – explanation of construction principle of the tree – establishing relation between parameters of the tree and objects of the problem space	4:30
PSF	T: Analysis of completed tree sketch with focus on the recursive relationship of the number of nodes on each level – devising three base equations – mathematical conversion of base equation to formula sought for	4:00
	C: Transformation of Tom's sketch into animated graphic – explanation of Tom's thoughts during the analysis – reference to recursion as another informatic problem-solving tool – derivation of the three base equations – conversion of base equation into final solution	4:30
	Total time	26:30

PC problem comprehension, *T* Tom's activity, *C* commentary level with animated sequences, *PA* problem analysis, *PSC* problem-solving of lower color configuration, *PSF* problem-solving formula

In the following commentary part, advantages and motives of the preceding activities of Tom are discussed. The learners were taught that an intensive analysis of the problem leads to important insights for an efficient and successful work on the task. Furthermore, the key finding used later during the course of the video was presented to the audience.

Problem-Solving of the Lower Color Combination Now, Tom works on the lower color sequence, which leads to the maximum amount of possibilities of different color sequences in the upper half of the rectangle. It is demonstrated to the audience how Tom uses the findings from the analytical phase and thus, within just a few minutes, is able to create a continuously expanding tree structure to realize the maximum case.

This procedure is clarified in the corresponding commentary part afterward by deducting the tree structure gradually and with additional explanations. In this phase, the fundamental idea of structured dissection by trees as an informatic problem-solving tool is illustrated and explained using a concrete example. The commentary part explains how the single objects of the problem space can be modeled by a tree structure. For example, it is demonstrated that the height of the tree equals the length of the rectangle and the number of nodes on every level equals the amount of upper color sequences.

Problem-Solving of the Formula In the last part of the educational core, Tom turns toward the question about the formula for calculating the number of possibilities in relation to the length n of the rectangle. He develops a recursive formula by analyzing the tree structure created in the previous step. He does so by asking himself how he can derive the number of nodes on one layer of the tree from the number of nodes on the layer above. Finally, Tom quickly specifies the correct formula, and hence, the problem is entirely solved. Next to the idea of structured dissection, a second idea, namely, recursion, is demonstrated as a tool in this part of the movie.

Evaluation

Immediately after the development of the concept, a low-quality demo version was produced using Windows standard tools. The film sequences of the background story had been replaced by a picture story, which consisted of drawings made from photographs from the crucial scenes – like the interview or Tom's greeting in the lab. The animations were simulated in PowerPoint and screenshots of it were embedded in the video. This demo version was presented at a symposium and discussed in the department. The resulted proposed amendments were included in the consequently produced professional cinematic production at the audiovisual center of the University of Potsdam. In the final version of the video, only the presentation of the picture story was kept due to reasons of time and cost reduction. The comments were acted out by professional speakers (a male and female voice alternating). Furthermore, the animations of the explanation part were done in professional quality. As a result, we produced an instructional video in high quality of 33 min in German as well as in English language.

First Evaluations Through Surveys

In the first step of the evaluation, the finished video was assessed through a survey. Sixty first semester students of computer science and business informatics watched the video and afterward filled out a questionnaire. The form included questions about prior knowledge in informatics, self-assessment about problem-solving, comprehension questions about the context, and questions about the personal opinion on the video concerning understandability and appropriateness of the video as a teaching tool. Eighty-five percent estimated their ability to solve a problem as "weak" or "rather weak." Consequently, those students belong to the target group of the video. The results of the questionnaire showed a high acceptance of the concept of the video, and furthermore they signaled the demand of systematic teaching of specific techniques to solve problems. Most of the respondents stated that the video helped them to get

deeper knowledge on how to deal with problems of CS. Fifty-eight percent expressed higher motivation on working on informatic problems because of the video. More than 70% of the students would approve of also learning other methods with the same concept. The comprehension of the video as well as the length of 33 min was evaluated as “very good” on average.

First Study on Learning Effectiveness

While the questionnaire was aimed on the subjective opinion of the students, Schütze (2013) examined in his study whether the video material was indeed effective for the learning outcome. The study is specified in Kujath and Schütze (2015). The evaluation of the study was based on two hypotheses. The first hypothesis claims that subjects of the group “with video” are more likely to find a solution than the ones of the group “without video.” From the group “with video,” 25% of the test students provided a correct solution – random mistakes were adjusted – whereas just 18% of the students of the group “without video” could solve the problem. This confirms hypothesis 1 in Schütze (2013), however, with an insufficient level of significance. According to hypothesis 2, subjects from the group “with video” used at least one method shown in the video, resulting in higher-quality solutions. The analysis of the solution showed that 17% of the group “with video” used at least one tool provided in the video, whereas no student of the group “without video” used such techniques. Based on these results, the second hypothesis is not significantly confirmed but at least not refuted.

Summary of the First Results of the Previous Evaluations

The prior analysis verifies a didactic relevance of the video. Even though the personal perception of the participants of the questionnaire is subjective, the authors see the high acceptance of the target group toward the teaching tool as an important precondition for learning motivation. The study of Schütze (2013) indicates a high effect on learning as well. However, this should be confirmed by further studies.

Extended Study on Learning Effectiveness and Analysis of the Target Group

Design of the Study

Due to the small number of participants and the lack of significance of the results presented in section “[First Study on Learning Effectiveness](#),” a second study with considerably more participants was designed. The subjects were recruited in their first semester with an online application form. Similar to the previous evaluation, the students were asked about their prior informatic knowledge and their self-assessment about their ability to solve problems. For quantifying reasons, different informatic contexts (coding, algorithms and data structures, automata theory, tree structures, graph theory, and recursion) were listed and required to be judged by the degree of comprehension on a five-tier scale from 1 (not at all) to 5 (completely). The topics of “tree structures” and “recursion” were relevant for the study. The self-report of the ability to solve problems included the options “strong,” “rather strong,” “rather weak,” and “weak.” To identify the possible reasons for unspecific work on the task and lack of informatic problem-solving methods, the students were asked to put themselves in one of the following four categories of problem-solvers:

- A** = “I master informatic problem-solving methods completely and I am able to use them” – in the following called category “**A_{all}**.”
- B** = “I know informatic problem-solving methods and I know how to use them. However, I don’t know when to use them” – in the following called category “**B_{when}**.”
- C** = “I do know informatic problem-solving methods, but I don’t know how to use them properly” – in the following called category “**C_{how}**.”
- D** = “I don’t know any informatic problem-solving methods” – in the following called category “**D_{nothing}**.”

Composition of the Participants After eliminating invalidly answered online surveys, 66 participants had been invited to the study. They were

divided into 2 groups with 33 students each. Based on their answers in the categories “prior experience in informatics,” “ability to solve problems,” and “problem-solving categories,” the subjects had been divided pre-selectively to establish a parity composition regarding the (assumed) problem-solving competence.

In terms of the selection of questions stated above, the answers resulted from the single sub-groups and the overall group are shown in Tables 3, 4 and 5.

Discussion of the Tasks The first task contained a relatively challenging 3-coloring problem. In order to solve the problem, a tree structure could have been constructed. Based on that, a recursion

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 3 Informatic prior experience of the participants regarding tree structures and recursions

Frequency in the	Degree of prior knowledge regarding tree structures				
	5	4	3	2	1
Group “with video” ^a	0	11	14	5	2
Group “without video”	4	9	12	5	3
Total sample	4	20	26	10	5
Frequency in the	Degree of prior knowledge regarding recursions				
	5	4	3	2	1
Group “with video” ^a	1	10	13	7	1
Group “without video”	2	7	9	8	7
Total sample	3	17	22	15	8

^aIn the table based on the results of the questionnaire, the total number in the group “with video” is only 32 and not 33, because participant T133 from this group did not answer the survey

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 4 Estimation of own ability to solve problems

Frequency in the	Self-assessment of ability to solve problems			
	Strong	Rather strong	Rather weak	Weak
Group “with video”	0	15	17	0
Group “without video”	3	14	16	0
Total sample	3	29	33	0

would have helped to derive the formula to find the amount of possibilities to color the graph for an arbitrary n . This part of the test was supposed to show how the single participants of the different types would solve such problem without any further advice. The second task – a coloring problem, too – was solvable with the methods demonstrated in the video. However, a transfer of knowledge needed to take place to some degree. For example, the number sought for in this task could not be deduced directly from the tree structure and the recursion, but rather by adding another sub-tree. Hence, the direct use of the methods shown was not enough, and therefore, a simple memorizing of the solution example in the video did not lead to the solution of this task. Additionally, both groups were given an additional condition: “Solve the problem with the aid of tree structures and recursion.” This was supposed to establish an equality of chances between the problem-solvers of the category B_{when} (don’t know when) from the group “without video” and the group “with video” by providing them with a hint about possible problem-solving methods. Furthermore, the hint was to encourage the participants from the group “with video” to actually use the methods presented in the video.

Procedure of the Tests

Both groups had been invited simultaneously in two separated lecture halls. The aim was to investigate the change of the problem-solving behavior after the presentation of the video in a comparative study. Two different coloring problems were presented to each group. Both groups were provided with the problem which was solved in the video by the fictive high-performer

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 5 Distribution of the problem-solving types

Frequency in the	Problem-solving type			
	A_{all}	B_{when}	C_{how}	D_{nothing}
Group “with video”	1	10	16	5
Group “without video”	2	9	18	4
Total sample	3	19	34	9

“Tom” as the first task. The group that had not seen the video solved the second task directly after the first one. Both tasks and a short discussion of the solution can be found in the appendix. The second group, the group “with video,” watched the video after solving the first problem, however, without any didactic comments. Since the task shown in the video was identical to the one the students just solved, the authors hoped for a higher motivation and attention performance. Directly after the video presentation, the group “with video” was asked to solve the second problem (For the sake of completeness, it must be added that the group “without video” also watched the video. However, they have seen it just after the test and after handing in their solutions.). Additionally, the test persons were requested to comment shortly on their work. The students had 35 min for each task.

Evaluation of the Solutions

Both authors independently evaluated all of the 132 solutions. They had no knowledge of the participants’ group belongings while evaluating. For the analysis, the pages with the solutions and the short comments of the participants were used. During the analysis it turned out to be problematic that subjects only gave very brief comments. Furthermore, the work on the solutions was not in chronological or textual order. To allow a significant as well as a secure evaluation, the analysis was restricted to explicit and evident structures.

Assessment Scheme and Discussion The solution drafts were examined separately and were classified into the following scheme:

- 1. Tree structure and recursion used completely, correctly, and employed to lead to the solution
- 2. Tree structure and recursion used just partially to some extent
- 3. Every other approach including “empty page”

Thanks to this method, the assessment could be performed comparatively fast and reliable based on the graphical sketches. The evaluation from both experts was mostly identical. In some cases,

different evaluations were unified in a subsequent discussion. Solutions unrelated to the context of the video were not considered in the study even though possibly leading to a solution. The evaluation resulted in two numerical values for each participant ranging from 1 to 3 for the work on the first problem and from 1 to 3 for the second problem. Hence, a qualitative improvement for the second problem existed, if the difference between the two problems was either +1 or + 2. If such an improvement occurred with a participant of the group “with video,” a learning effect is assumed. Since it is possible that improvements occur in the group “without video” as well (especially because of the additional hint), learning effectiveness caused by the video is only given, if improvements of the solution of the second problem are significantly higher in the group “with video.”

Results

Only 12 out of 66 participants (18.2%) used tree structures and recursion from the very beginning, that is, without any clues about the methods. Five of them (7.6%) solved the problem completely and correctly. Despite a few exceptions, the remaining 54 solutions did not involve any specific informatic methods. They were mostly worked on by simply trying every color combination and did not lead to a quantifiable success. Hence, these problem-solvers correspond to the target group of the video.

For the second problem, many improvements were noticeable in the assessment scheme explained above. In the group “with video,” 19 out of 33 participants (57.6%) showed an improvement in their approach as well as 11 out of 33 participants (33.3%) within the group “without video” (see Table 6):

These findings equal a significance level of 5%. If one takes the degree of the solution

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 6 Improvements of the solution w.r.t. groups

Group	Participants	Improvements	Percentage
“With video”	33	19	57.6%
“Without video”	33	11	33.3%

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 7 Degree of improvement

Frequency in the	Degree of the solution improvements (dosi)				
	-2	-1	0	1	2
Group with video	1	2	11	15	4
Group without video	0	1	21	11	0

improvements (dosi) into account, that is, to which extent the solution improved, an improvement by the value of 2 occurred for 4 out of 33 participants (12.1%). There are no occurrences of this type in the group “without video” (0.0%). In both groups, a small number of deteriorating solution approaches were noticed which shall not be commented here. These observations are summarized in Table 7.

Who Benefits Most from the Video?

In the following chapter, we aim to investigate how those participants who improved their approaches in the second coloring problem can be divided using the selection criteria described in section “[Composition of the Participants](#),” i.e., “informatic prior experience,” “ability to solve problems,” and “problem-solving types.” The following tables include the percentages of subjects who improved in every single answer category. This is supposed to verify and specify the target group definition.

Prior Experience in Informatics By using prior experience with tree structures as an example, it shall be demonstrated how prior experience in CS affects the individual’s learning success. Table 8 shows how many participants out of the total number of the respective criterion per group improved their approach during the second coloring task. For clarity reasons, the values explained in section “[Composition of the Participants](#)” regarding the prior knowledge were combined in the following manner: the values 5 and 4 equal to “high,” 2 and 1 equal to “low,” and the value 3 corresponds to the attribute “intermediate.”

The group “with video” includes the most participants with an intermediate degree of prior knowledge about tree structures. 64.3% of the

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 8 Percentage of improvement by prior knowledge about tree structures

Who has improved? Distribution by prior knowledge about tree structures			
Group	“High”	“Intermediate”	“Low”
“With video”	63.4% (7/11)	64.3% (9/14)	42.9% (3/7)
“Without video”	46.2% (6/13)	25.0% (3/12)	25.0% (2/8)

participants (9 out of 14) showed an improvement after watching the video. In the group “without video,” it was only 25% (3 out of 12). Furthermore, the other participants of the group “with video” performed better as well. 63.4% of the participants of the group “with video” with a high degree of prior knowledge improved their approach in the second task compared to only 46.2% of the group “without video.” Concerning the participants with a low degree of prior knowledge, 42.9% of the group “with video” were able to improve in contrast to just 25.0% of the group “without video.”

In the group “with video,” participants with a high or intermediate level of prior experiences benefitted most according to these results. Participants with low prior experiences performed significantly worse in comparison. In the group “without video,” a high degree of prior experience about tree structures seemed to be inevitable in order to deal with the given problem.

Self-Assessment None of the participants considered his or her skills in problem-solving as “weak.” Table 9 shows how many participants of the respective criterion of each group improved their approach in their second task. Most of them belong to the categories “rather strong” and “rather weak.” Since there was no participant of the group “with video” who considered himself “strong” or “weak,” a statement cannot be made here.

Regarding the group “with video,” 60% of the “rather strong” category and 58.8% of the “rather weak” participants improved their approach after watching the video. According to the present data, the “rather strong” problem-solvers improved slightly more. In the group “without video,” the participants who consider themselves as “rather

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 9 Percentage of improvement by self-assessment

Who has improved? Distribution by self-assessment				
Group	Strong	Rather strong	Rather weak	Weak
“With video”	0.0% (0/0)	60.0% (9/15)	58.8% (10 /17)	0.0% (0/0)
“Without video”	33.3% (1/3)	21.4% (3/14)	43.8% (7/16)	0.0% (0/0)

Problem-Solving in Computer Science, Learning from a Gifted Peer, Table 10 Percentage of improvement by problem-solving categories

Who has improved? Distribution by PS categories				
Group	A _{all}	B _{when}	C _{how}	D _{nothing}
“With video”	0.0% (0/1)	80.0% (8/10)	56.3% (9/16)	40.0% (2/5)
“Without video”	50.0% (1/2)	44.4% (4/9)	27.8% (5/18)	25.0% (1/4)

weak” improved the most. With 43.8% it is significantly higher than in the section of the strong problem-solvers.

Problem-Solving Categories For didactic implications, it is of high importance to be able to assign the problem-solver to one of the problem-solving types mentioned above. We are going to investigate how the problem-solving types distribute among the participants who have improved in the second task (Table 10).

In the group “with video,” there were ten participants of the problem-solving type “B_{when}” (don’t know when), which means, according to them, they are able to use informatic problem-solving methods, but they are uncertain about when to use them. 80% of these participants showed an improvement after the presentation of the video compared to just 44.4% of the group “without video,” which is less than half of that group. A similar ratio is found in the category “C_{how}” containing those participants who, according to their statement, are aware of certain methods but do not know how to use them properly. Sixteen participants belonged to this category and watched the video. 56.3% out of them improved their work in the second part. The group “without video” included 18 participants from this category of whom 27.8% improved their approach. The present data suggests that participants from the problem-solving type B_{when} benefit most from the video material.

Summary and Perspective

There is a high demand for targeted teaching of problem-solving competences especially for weak problem-solvers. The isolated presentation of informatic problem-solving methods on an abstract level (like “a graph is a 2-tuple ...”) is not regarded as sufficient, most notably by first-year students. To close this gap, a learning tutorial was produced, which illustrates the approach to informatic problems by a very strong problem-solver dealing with a coloring problem. The chosen form of presentation with a fictive high performer who thinks aloud while solving this problem was considered as positive and motivating by most of the test persons. The results of the present analysis of the learning effectiveness are very likely to not be random considering the significance level of 5%. They prove the learning effect of the tested video. Furthermore, it should be considered that the video was shown without any further comments and the participants were asked to solve the second coloring problem directly afterward. With appropriate didactical preparation before and after the presentation, the video is expected to be even more effective. Hence, a teaching unit about tree structures and recursion in a specific problem-solving context is going to be constructed, during which the video will be used as an introductory example. During the course of the unit, the video content will be further consolidated.

Furthermore, the question which type of problem-solver benefits most of this kind of video, and thereby the question of further clarifying the target group description, was investigated in this study. For the interpretation of the data, the participants' self-assessment statements were assumed to be sufficiently valid. As expected, the group which estimated their prior experience about tree structures as "high" or "intermediate" performed best after watching the video – the ones with an intermediate level even slightly better. For learners with low and no pre-knowledge, the video is rather unsuitable. The "rather weak" and "rather strong" problem-solvers performed equally well. However, a statement about the "weak" and "strong" problem-solvers cannot be made as there were no participants present in the group "with video." It can be said though that learners with a certain ability of problem-solving strategies are more likely to have a positive benefit from watching the video. Contrary to expectations, there was a high degree of improvement of the problem-solving type B_{when} from the group "with video" (compare Table 10). The percentage in this category is almost twice as high in comparison to the same problem-solving type in the group "without video," even though those participants were provided with the hint about tree structures and recursion as well. This suggests that the self-assessment was not sufficient enough, meaning that many participants did not know how to use informatic problem-solving methods and had to be taught first via video. Consequently, in future studies the self-assessment and the question about the problem-solving type in particular should be replaced by valid test data.

Appendix

Task 1 (35 min)

A horizontally lying rectangle of length n is divided into two rows and n -columns of 1×1 -squares:

Each of these 1×1 squares is supposed to be colored in one of the following colors: white, gray,

and black. Squares which meet at one of their edges cannot have the same color.

Another condition applies: The lower half of the horizontal rectangle is already colored in an arbitrary color sequence. How many different options to color the upper half correctly are possible?

Answer: The amount depends on the length n of the rectangle and the texture of the color sequence in the lower half.

- (a) How does the lower color sequence need to be colored to achieve the highest amount of coloring possibilities?
- (b) How can one always achieve the highest amount for every n ?

(Hint to solution (not for participants): The approach in the video is as follows: first, there is an in-depth analysis of the task. This leads to the awareness that the maximum amount of coloring possibilities can only be achieved if two colors appear alternatingly in the lower row. Thus, a decision tree can be constructed, which displays the color options of the upper row with growing length. Based on this tree, the formula of the maximum amount of possibilities can be derived:
 $A_n = F_n + F_{n-1}$)

Task 2 (35 min), after presentation of the video:

We encode positive integers 1, 2, 3, 4, etc. with the digits 1 and 0.

The common rules for binary numbers apply and there is no leading zero. Additional rule: In the 0–1 sequences, two 1s cannot be directly in a row.

Allowed: 1, 10, 100, 101, 10000, 1001, ..., 10010100010100010101010001, etc.

Not allowed: 1011

These sequences of numbers represent the natural numbers in the order of appearance. Consequently, 1 encodes 1, 10 encodes 2, 100 encodes 3, 101 encodes 4, 1000 encodes 5, etc. The digit sequences are sorted first by length and then by lexicographical order.

(Hint to solution (not for participants):

Again, a tree structure can be used to model the possibilities for the first numbers. The tree structure also helps to recognize the Fibonacci numbers. Fibonacci numbers always occur by adding a new digit, $1 = 1$, $10 = 2$, $100 = 3$, $1000 = 5$, $10,000 = 8$, etc. Similar to the first problem, the formula for the number sought for can be derived from the tree structure. However, on the lowest level the addition of a sub-tree is necessary. The correct number is **2000.**)

What Is Programming?

Programming, also referred to as coding, is the process of writing, testing, debugging/troubleshooting, and maintaining the source of code of computer programs. This source code typically consists of a list of instructions that can be compiled into an executable computer program. The source code is written using a programming language, often with the aid of an integrated development environment (IDE). The target platform on which a specific program can be executed, as well as many of the features or behaviors that can be encoded, is often dependent on the specific programming language and IDE used.

Programming Languages

A wide variety of programming languages are used in secondary schools worldwide. Many different factors play a role in determining the choice of language used. These include the familiarity of teachers with a particular language, the available hardware and/or software, whether the focus of the curriculum is on information

technology competencies or on computational thinking, and many other factors. Popular choices could include (Kemp 2014):

- Visual languages – Languages like Scratch or Kodu are often used at both primary and secondary school level to introduce pupils to programming concepts.
- General-purpose textual languages – Languages like C# or Java are popular options and allow a very wide range of possible applications to be developed.
- Declarative textual languages (markup) – HTML and CSS are languages used extensively for Web development. These languages do not support computational problem-solving directly; however, they are often used in combination with languages such as JavaScript to provide computational abilities.

Outcomes in Secondary Schools

There have been many attempts to make some form of programming education ubiquitous among school learners. Projects such as “Hour of Code” (hourof-code.com) have introduced millions of learners from more than 180 countries to basic coding in efforts to “demystify” the concept of programming. However, for most secondary school learners worldwide, formal programming education is, at best, an optional subject.

The primary aim of programming education in school is usually not to teach technologies, since these technologies change rapidly, but rather to teach problem-solving skills and the ability to think computationally. When students program, they have to firstly construct a solution to a given problem in the form of an algorithm. This solution then, secondly, has to be communicated in the syntax of a chosen programming language in a way that is perfectly unambiguous (Saali 2012; Szlávi and Zsakó 2006). This aids in the development of both logical thinking and the means to communicate clearly (Hromkovič 2006).

Computing at school (computingatschool.org.uk) breaks the process of computational thinking into the following components (Kemp 2014):

- Decomposition – breaking a problem up into smaller subproblems
- Pattern recognition – finding similarities in the behaviors and states you are modeling
- Abstraction – reducing the functionality/actions taken to the absolute minimum required
- Pattern generalization – defining concepts in their simplest form in order to reuse these in future problems
- Algorithm design – constructing a solution to the specific problem

International Trends

In the past, many national curriculum statements for secondary school programming education focused on the technology aspects related to programming. In recent years there has been an increased focus on the aspects related to the development of computational thinking and less focus on technology-specific aspects. There is also an increased international recognition of the need for most learners to possess basic programming skills in order to be considered digitally literate.

Definition

Programming language selection refers to the process of choosing a language for use in the initial programming courses in an academic curriculum.

Introduction

The choice of pedagogical programming languages for introductory or advanced computer science, information systems, or informatics courses is a major decision that requires considerable thought because the programming language used in a teaching environment can significantly impact not only how courses are taught but also their effectiveness.

An ideal situation would be a single language that could be used to cover all needed paradigms and topics in at least the first one or two programming courses rather than using different languages

in each course. Kummerfeld and Kay (2003, p. 105) note that “students using an unfamiliar or new programming language waste considerable time correcting syntax errors.” In the authors’ experience, it can take 4 or more weeks of lectures and coding exercises to teach students a second programming language, course time that could be used to cover other essential topics.

This entry examines aspects of academic programming language selection with the goal of aiding academics in choosing a language that will meet the needs of their curriculum. A sound choice will both provide a solid introduction to basic programming skills and quickly elevate those skills to a level at which informatics, software engineering, and computer science majors can be more effective in subsequent computing courses.

We start by considering the language selection decision-making process that an academic program needs to conduct, detailing a number of factors and external pressures that faculty might need to consider. Finally, we touch on some emerging trends that may affect choices and changes in coming years.

The History of Language Selection

In 1978 the ACM Special Interest Group on Programming Languages (SIGPLAN) sponsored a conference on the History of Programming Languages (HOPL), during which it was proposed that language importance should be assessed based on the following criteria: (1) the language has been in use for at least 10 years, (2) the language has significant influence, and (3) the language is still in use (Bergin and Gibson 1996). A study by Soloway et al. (1989) attempted to find a better match between a language and an individual’s natural skills and abilities, exploring the relationship between the preferred cognitive strategies of individuals and programming language constructs.

Howatt (1995) proposed an evaluation approach for programming languages, with criteria that included the broad categories of language design and implementation, human

factors, software engineering, and application domain. Howland (1997), too, presented an extensive list of criteria that the author considered to be important in choosing a language for introductory computer science instruction but concluded that the selection of a programming language should be made primarily on the basis of how well key programming concepts may be expressed in the language.

The Computing Curricula 1991 recommendations for the introductory programming course were examined by King (1992), and he reviewed the creation of several important languages as well as the emergence of various programming paradigms during the 1980s before going on to propose his own set of criteria for the selection of programming languages.

By the turn of the century, both the object-oriented (OO) paradigm and the recognition of the importance of information security were greatly impacting language choice. In a study of language selection for CS1 and CS2 classes, the Ad Hoc Advanced Placement Computer Science (AP CS) Committee (2000) noted three main requirements: emphasis on object orientation, need for safety in the language and environment, and a desire for simplicity. Wile (2002) pointed out that programming language choice is subject to both technical and social pressures, including those of the problem domains the languages are intended to address, the conceptual and computing models that underlie the designs of the languages themselves, independent of their particular problem domains, and the social and physical contexts in which the languages are used. Roberts (2004a) observed that an increasing number of universities were adopting Java as the programming language for their introductory course, not only because of the growth in the popularity of the OO paradigm but also due to the decision by the College Board to use Java in the AP CS program. Roberts (2004b) went on to reflect that two additional challenges were negatively impacting pedagogy: (1) the number of programming details that students must master had grown, and (2) the languages, libraries, and tools on which introductory courses depend were undergoing more rapid

change than in the past. Finally, Gee et al. (2005) noted a divergent trend toward the use of scripting languages to teach programming concepts because they provide not only a proper programming environment but also a tool for the formation of active web pages.

Selection Approaches

Some languages were developed with the intent of solving problems, while others were designed to make teaching algorithms easier (Parker and Davey 2012). This has led to two often conflicting alternatives about which languages should be used in university courses: should academics choose a language that is commonly used in industry, or should they choose a language that best supports concept development in students? Thus, throughout the history of language education, there have been two distinct arguments for language selection: pragmatic versus pedagogical.

Pragmatic Approach

The pragmatic approach favors choosing a language that will assist students in getting a job upon graduation. This approach views the language selection approach's most important consideration to be a language's industry acceptance as well as the marketability of individuals proficient in its use.

Industry Acceptance

Industry acceptance refers to a language's market penetration in industry (Riehle 2003), i.e., the extent to which a language is used in business and industry. Sometimes referred to as industrial relevance, this can be determined based on current and projected usage, as well as the number of current and projected positions. Stephenson (2000) rates this factor as the greatest influence in language selection, as indicated by 23.5% of schools participating in his study. Lee and Stroud (1996) note that real-world acceptability once had little weight, as indicated by the earlier use of ALGOL and Pascal, but that attitude seems to be changing. Their opinion is that students

having an industrially accepted language on their resume is a significant consideration. A 2001 survey of all Australian universities indicated that perceived industry demand was the major factor in their selection of an introductory language (de Raadt et al. 2003). King (1992) concurs that many language decisions are made on the basis of current or projected future popularity, noting that there are a number of practical benefits to choosing a popular language including greater student motivation to study a language that they have heard is in demand, as well as a good selection of books and language implementations available for more popular languages.

Marketability

Marketability refers to high employability of graduates. This may include regional, national, or international marketability, depending on the placement of a program's graduates. When language selection is driven by demand in the workplace, i.e., what employers want, not only can that factor into improving the likelihood of quality future employability, but it can also increase student enthusiasm when studying a language if they feel it may improve their employability (de Raadt et al. 2003).

Language marketability is considered in several studies. In the census of introductory programming courses conducted by de Raadt et al. (2003), the most commonly listed factor in language selection (by 56% of the participants) was the desire to teach a language that equips graduates with marketable skills. Watt (2000) notes the need for transferable skills that will be useful in the students' future careers, while Emigh (2001) contends that the primary concern in language evaluation must be the demand in the workplace and employers' expectations of graduates. In fact, graduates' marketability can be further enhanced by exposing them to multiple languages (de Raadt et al. 2003). For example, a progression from C to C++ to Java will provide graduates with the qualifications for more advertised positions than exposure to any single language in isolation. Extrinsically motivated students aspiring to a lucrative career may

demand to be taught those tools that are currently in vogue in the industry, and in such cases, universities may have to accept that pedagogical issues in the choice of platform and language must be secondary to marketability concerns (Jenkins 2001).

Pedagogical Selection

Many academics question whether industry trends should drive changes in curriculum and programming courses as they often seem to (Smolarski 2003; McIver and Conway 1996; Howland 1997). Their stance is that decisions regarding the language used in an introductory course should be based on how well it underscores fundamental skills that help to make any student-developed software well-written and error-free as well as to prepare students for ensuing courses, rather than on what language is currently favored by employers (Smolarski 2003).

Avoiding the Complexities of Industrial Environments

These arguments also bring to the forefront the possibility that attempting to teach problem solving while simultaneously introducing a professional grade language into the first course conflict because students are distracted by difficulties associated with that language and its environment (Johnson 1995; Jenkins 2002; Gee et al. 2005; Allison et al. 2002; Kelleher and Pausch 2005). A language that requires significant overhead to address even trivial problems forces the language, rather than the techniques of problem-solving, to become the object of study (Zelle 1999).

Clear Problem-Solving Principles

A teaching language should be designed in such a way that it enhances teaching the fundamentals of basic programming tasks. This is the argument espoused by Wirth (1993), Kölling et al. (1995) and many other developers of teaching languages and is commonly invoked by proponents of the various "pure" teaching languages. The argument generally concludes that it is better to adopt a language not commonly used in industry.

Those sharing this viewpoint favor adopting a teaching language that promotes conceptual cleanness and efficiency as well as other instructional goals, rather than using a real-world production language whose rich feature set can introduce unnecessary complexity (Kölling et al. 1995).

Language Selection Process

Common problems that may be faced when designing an introductory course range from interdepartmental political squabbles if the course is a service course to logistical challenges if the course must accommodate a substantial number of students (Solntseff 1978). Clearly, strife surrounding the introductory programming language course and the language appropriate for that course has been ongoing for decades (Smolarski 2003). With no generally accepted approach for performing the evaluation, the selection of a programming language for instructional purposes is often a contentious task. The process often takes the form of an informal faculty discussion, with various faculty members championing their preferred language. The process continues until an eventual consensus is reached or the dominant faction wears down the opposition. As the number of faculty, students, and language options increases, this process becomes increasingly daunting. As it stands, the language selection process lacks structure and is seldom replicable (Parker et al. 2006a).

Many of the factors influencing the selection of a programming language for an introductory course at one US university is ably discussed in Smith and Rickman (1976), a study praised for its “comparable thoroughness” (Solntseff 1978). Parker et al. (2006a, b) examined over 60 papers relevant to language selection in academia and presented their criteria to be used when selecting a language for programming courses. Their study resulted in a selection approach that involves weighting each of those selection criteria based on its relative importance in each unique selection process.

Selection Criteria

Several factors should be considered when selecting a programming language. While different curricula place greater emphasis on different factors, generally all must be considered.

Parker et al. (2006a) compiled an extensive set of selection criteria and proposed a process for the application of those criteria to evaluate various languages to be used in programming classes. The selection criteria take into account the programming features of each language under consideration, the appropriateness of each of these features for teaching beginning (and perhaps advanced) programming concepts, the current and future industry acceptance of each language, the availability of quality textbooks, the costs associated with adopting each language, the infrastructure and support implications of each language, and the impact of the decision on the tactical and strategic direction of the department and curriculum. Parker et al. (2006b) carefully analyzed the preceding selection criteria. Those with commonalities were grouped together to produce the programming language selection criteria shown in Table 1, with a few enhancements added.

Reasonable Financial Cost

Reasonable financial cost refers to the price to acquire the programming language software and/or the development environment. While this may involve individual packages or a site license for a network version, educators should inquire about academic discounts for educational institutions, an alliance in which the university or department can enroll, or even a free, downloadable version.

Availability of Student/Academic Version

If a student version or academic version is available, students can install the development environment on their personal machine, making it convenient for them to work on their assignments even if the computer lab is not accessible. However, if the department has no option other than to use a network-based version because a student version is unavailable, students may

Programming Language Selection for University Courses, Table 1 Higher-order selection criteria

Availability of support
Instructor and staff training
Student experience
Anticipated experience level for incoming students

be forced to work on their assignments in campus labs, restricted by hours of operation, availability of transportation, etc. If an academic version has a limited feature set, then the benefit to the students may be considerably reduced, but a student version should at least be considered.

Academic Acceptance

Academic acceptance refers to the popularity of a language at other academic institutions. This can be gauged by assessing current or projected use at other institutions. For example, as OO programming increased in popularity and the College Board decided to emphasize Java in

the AP CS program, a number of universities, colleges, and secondary schools adopted Java as the programming language for their introductory programming courses (Roberts 2004a).

Availability of Quality Textbooks

The availability of quality textbooks is impacted by many factors. The life cycle stage of the language affects the availability of textbooks, because while it is often difficult to find a quality textbook for a newly released language, more textbooks become available over the time it takes for a language to mature. The academic acceptance of a language also plays a significant role in the availability of textbooks because the more widespread the use of a language in academia, the greater the textbook market for related textbooks. Publishers service that market by offering a larger selection of textbooks. Finally, textbook availability may also be affected by the teaching approach used. For example, functions-first, objects-first, or objects-early are all approaches used to teach OO languages, but fewer recent texts present the material from a functions-first perspective. Availability of reference books should also be taken into account (Lee and Stroud 1996).

Stage in Life Cycle

A language's stage in the programming language life cycle affects not only textbook availability, as discussed earlier, but it may also impact the widespread use of a language in both industry and academia. Universities generally prefer a language that is still in its earlier stages, rather than one like FORTRAN that is in its declining years. The programming language life cycle as described by Sharp (2002) is based on the natural principles of growth, maturation, and decay. The processes of natural advantage and evolution operate in the world of programming languages just as they operate in the biological domain, but in the case of languages, the main forces are efficiency of expression versus profitable adoption.

Industry Acceptance

As discussed earlier, industry acceptance is the market penetration of a particular language in industry (Riehle 2003). While many academic

programs place great emphasis on this factor, Howland (1997) objects that too many languages are chosen simply because of their current popularity instead of on a sound pedagogical basis.

Marketability

Marketability refers to the employability of graduates and was discussed earlier when pragmatic concerns were considered. Language selection is often driven by workplace demand because marketable skills influence future employability. Emigh (2001) cautions, however, that 2 or 3 years may lapse between when a student takes an introductory programming course and when he or she enters the workforce. Even curricula that adopt newer programming languages can make no guarantee that employers will still be using those languages when the students are hired.

System Requirements

The system requirements associated with a programming language or its development environment should be considered in the selection process. The amount of hard disk space needed for software installation, operating system compatibility, and the memory requirements for optimal software performance all factor into the decision. Both student and lab computers must meet the minimum requirements of the selected language.

Operating System Platform Dependence

Some languages are platform dependent, meaning that they will only run on systems using certain operating systems. For example, the Swift programming language can only be used on macOS, iOS, watchOS, tvOS, OS X, and Linux platforms. Other languages, such as Java, are platform independent, meaning that Java development environments are available for a variety of operating systems. Platform dependence may be a deal breaker for faculty members who are fanatic about a particular operating system.

Source Code Availability

Source code availability refers to whether a language and its associated development environment are open source or proprietary. Open-

source software allows users to modify, change, and share the source code. For example, PHP is an open-source language and can be easily modified by any member of the open-source community. On the opposite end of the spectrum, Microsoft is responsible for additions, deletions, or modifications in any of the languages supported by the .Net framework, while Sun is responsible for the ongoing evolution of the Java language.

Development Environment

Development environments range from simple text editors and command-line compilers to fully interactive and integrated development environments (IDE) (McIver 2002). The development environment can improve or impair productivity (Jensen 2004). Unless an IDE is easy to use, students may be distracted by the environment rather than concentrating on learning programming concepts (Kölling et al. 1995). However, well-designed programming environments assist students in learning to program (Eisenstadt and Lewis 1992).

Debugging Facilities

Although debugging facilities may be considered part of the IDE, when assessing a programming language, one should specifically evaluate the diagnostic aids associated with the language (Tharp 1982). Programming environments must contain extensive tools for tracing and debugging (Ad Hoc AP CS Committee 2000). Error diagnostics should be clear and meaningful (McIver and Conway 1996), and the language should not only be robust but must also be graceful in failure (Conway 1993).

Ease of Learning Fundamental Concepts

The learning curve differs greatly between languages or IDEs. For example, Python is widely considered to be simpler to learn than a .Net language like C#. Basic concepts include sequence, selection, and iteration, as well as arrays, procedures, basic input/output, and file manipulation. In addition to ease of learning, the language must have a concise syntax and straightforward semantics (Conway 1993).

Coding Safety and Support for Secure Code

Coding safety is assessed by whether the language offers features like strong type checking and array bounds checking while avoiding features like variants and pointers in unsafe mode. Kölling et al. (1995) note that a language should have a safe, statically checked type system, with no undetectable uninitialized variables and no explicit pointers. Support for secure code involves the inclusion of security-related features like Java's sandbox, which limits the memory addresses that a Java program can access.

Advanced Features for Subsequent Courses

Some academic programs use a single language to introduce basic programming concepts in an introductory course and then to progress to advanced concepts, like multithreading, in a subsequent course. In such scenarios, it is critical that the programming language includes sufficient advanced features to support an advanced programming course.

Scripting or Full-Featured Language

Educators may also want to consider scripting languages in addition to full-featured languages. Scripting languages like Python offer sufficient richness to cover most of the requirements of an introductory course while avoiding many implementation issues and reducing the complexity of the development environment. Full-featured languages, on the other hand, may offer a more complete set of language features that an instructor may want to address.

Web Development Support

Given the prevalence of web-based systems, it is essential that today's students have the skills to develop web-based applications. Programming languages offer varying levels of web development support. Web development capabilities are not limited to scripting languages, discussed above, but are offered by full-featured languages like ASP.Net that provide a high level of support for web development.

Mobile App Development Support

Today's students make extensive use of cell phone apps. The choice to consider mobile application

development limits the selection of languages that can be considered due to platform considerations. App development languages for Android are not the same as those used for Apple iOS app development. For example, two languages that have recently emerged are Kotlin and Swift. Kotlin is one of the official languages for Android development, while Swift was created by Apple to work with primarily iOS and a few additional platforms. More mainstream languages like Java, C#, and Objective-C can also be used for app development, but the field of language options is still narrowed considerably. Emulators and simulators for mobile design and development may help alleviate the platform issue.

Target Application Domain Support

Target application domain support could also be referred to as "problem domain." If the programming course is serving a particular problem domain, the extent to which a language supports programming for specific applications must be considered (Howatt 1995). Examples of application domains include FORTRAN's support for scientific programming, COBOL's support for business data processing, and RPG's support for report generation. If a programming course is being developed to serve Electrical Engineering, C or C++ may be the preferred language. If a programming course is designed to serve a data science program, languages known to support data analysis, like Python, should be considered.

Methodology or Paradigm Support

Methodology or paradigm support assesses how well a programming language supports the paradigm under consideration. For example, if the OO paradigm is being taught, then the language must support integral OO concepts like abstraction, polymorphism, inheritance, and encapsulation. Similarly, if the aim is to teach event-driven programming, then IDE support for a graphical user interface (GUI) and ease of implementing graphical components is essential.

Teaching Approach Support

Teaching approach support refers to how well a language supports the teaching approach

preferred by the faculty. For example, the intent of the course may be to teach programming concepts with the language simply serving as a vehicle through which those concepts are reinforced, or it may be to teach the features of a particular language, such as using C# to develop an advanced user interface.

Availability of Support

This refers to the availability of support staff, including tutors, computer lab staff, and network administrators, to support the teaching and administration of a language. Language evaluators must consider the likelihood that their language questions, as well as those of the students, will be answered (Cunningham 2004). This should also take into account the availability of support through forums or listservs on the Internet, as well as vendor support (Tharp 1982). The availability of other resources like teachers' guides, example programs, student workbooks, and programming assignments should also be evaluated. Support may also involve something as basic as someone who can install a language and its IDE on a server, so it is accessible to all students. It may also include the availability of student tutors who have previous experience with the language.

Instructor and Staff Training

The training required for instructors and support staff, the time needed to learn a language or its IDE, and the availability of qualified instructors to teach a particular language must also be taken into consideration. Adopting a new language requires a willingness on the part of the department to invest in training its instructors because they “must continuously enrich their qualifications and implement new training methods and techniques supplemented with practical methods and techniques supplemented with practical experience while teaching a new language that is as new to them as it is to their class” (Emigh 2001, p. 2).

Anticipated Experience Level for Incoming Students

The anticipated programming experience level for incoming students is important because students' previous experience and training can

positively or negatively impact their grasp of new programming paradigms and languages (Traxler 1994). If students coming into a program have been previously exposed to a particular language, then it may influence language selection. If a program consistently sees incoming students with little or no programming experience, it may be necessary to adjust its requirements and its programming language selection accordingly.

Developing Trends

Those performing programming language selection must be aware of trends that may require changes in course content. Educators must, however, take care not to be overly influenced by trends, because they are just that. Trends change from year to year, and educators must provide students with a firm grasp of the fundamentals of programming even at the risk of ignoring trends. That said, increased reliance on functional programming languages, the importance of data science, and mobile app development all have a potential impact on what is covered in courses.

Functional Programming

Functional languages use side effect free functions as a fundamental building block in the language, rather than objects or procedures.

Functional programming focuses on the application of functions to arguments. In fact, the main program is itself a function that is defined in terms of other functions. Functional programming has no implicit state and places its emphasis entirely on expressions or terms (Hu et al. 2015).

Functional programming was introduced in the 1950s and is experiencing a resurgence in recent years with the popularity of languages like Haskell, Clojure, and Scala driven by explosive growth in the use of smartphones and connected devices.

As computers, tablets, smartphones, and IoT gadgets become ubiquitous, servers can act as bottlenecks to performance. The functional programming model allows sections of software to more easily and efficiently run in parallel across different CPU cores or machines,

without requiring complex synchronization. This gives the functional paradigm an edge over the OO approach when doing concurrent processing such as web requests (Puryear 2016).

Functional programming is generally more difficult for students to comprehend than other paradigms. It is more intuitive for them to view the world as a group of interacting objects rather than attempting to model everything as functions. As such, the resurgence of functional programming may seem to be of little concern when selecting a language for introductory programming courses. However, it is relevant to this discussion because “there is growing interest among some academics to introduce functional programming and functional thinking as early as possible within the computer science curriculum” (Winter 2014, p. 33).

Data Science

Whether you call it big data, data science, data analytics, or something else entirely, it may seem incongruous to include it in a discussion of programming languages. However, as the importance of data science continues to increase, the programming languages used to support data science may begin to influence the selection of a language for programming courses. R and Python are two of the more popular open-source programming languages for data analysis, while Scala and Julia may also be encountered in this domain.

Python is of particular interest in this discussion because it is widely touted as being easy to learn in comparison with most other programming languages. Python is both easy to learn and simple to use (Newman 2012). Many features of Python facilitate both teaching and learning, such as a simple and flexible syntax, immediate feedback, easy-to-use modules, and strict requirements on proper indentation (Grandell et al. 2006). According to an analysis published on the ACM (Association for Computing Machinery) website, Python has become the most popular language for teaching introductory computer science in the United States (Guo 2014).

When taken together, the increasing importance of data analytics, the widespread usage of

Python in data analytics, and Python’s shallow learning curve have combined to result in many universities adopting Python as their introductory programming language.

Mobile App Development

The proliferation of smart phone usage and their ubiquitous phone apps have made mobile app development one of the hottest trends in software development. The thorniest issue, as addressed earlier, is the platform, since different programming languages are used to develop Android apps and Apple iOS apps. Android is available for dozens of smartphone models, meanwhile iOS only for a handful of iPhone and iPad models developed by Apple (Dogtiev 2017). At the time this was written, Android had 66.74% of the market, while iOS had only 31.46% (NetMarketShare 2017). Regardless of the platform chosen, projections show that by 2021, the total app downloads will jump to a stunning 352 billion (Dogtiev 2017). Mobile app development is a critical trend that may shape programming language selection for years to come.

Observations

The reality is that the choice of a programming language for introductory courses often involves compromise. While there are economic, political, and pedagogical factors that must be considered in the decision-making process, the importance of each of these factors may depend on the specific aims and priorities of the institution, educator, or course. Educators must be certain that none of the factors in the above criteria are neglected or sacrificed to more highly visible concerns (McIver and Conway 1996).

Language selection has long been a difficult and unstructured task. Few issues in the computing education world are as strategically important or as contentious as the choice of programming language (Jensen 2004). However, the programming language used in the introductory programming course can have a significant impact on how the course is taught as well as its effectiveness (Parker et al. 2006a).

Programming Languages for Secondary Schools, Java

Torsten Brinda and Matthias Kramer
Computing Education Research Group,
University of Duisburg-Essen, Essen, Germany

What Is Java?

Java is one of the most popular and widely used object-oriented programming languages. According to the TIOBE index (See <https://www.tiobe.com/tiobe-index/>), which is an indicator of the popularity of programming languages, Java has been among the three most popular programming languages (together with C and C++) for 17 years in 2019 and currently holds and has been holding the top position over a long period of time in the past. The current significance is also confirmed by the annual survey conducted by Stack Overflow, which had more than 100,000 participants in 2018 (See <https://insights.stackoverflow.com/survey/2018>). Even with the perpetual increase in web development technologies, such as JavaScript and SQL, Java still plays an important role for all participants, from web developers and system administrators up to data scientists. Especially in Europe and India, it guarantees top-paying jobs (See <https://insights.stackoverflow.com/survey/2017>). Java was designed by James Gosling at Sun Microsystems

as a simple, object-oriented, distributed, interpreted, robust, secure, architecture-neutral, portable, high-performance, multithreaded, and dynamic language in the first half of the 1990s (See Sun Microsystems 1995), where it started as a part of a larger project to develop advanced software for consumer electronics and has since then been continuously developed further (initially by Sun Microsystems and since 2010 by Oracle after taking over Sun). The spread of Java began around the mid-1990s and thereafter at the time when the World Wide Web gained more and more popularity through web pages created with the Hypertext Markup Language (HTML), related web browsers with a graphic user interface (such as Mosaic and Netscape), and more and more devices being connected to the Internet. This resulted in the need for a compact, yet reliable, robust, and powerful language for developing programs for this scenario (See Claus and Schwill 2006).

The syntax of Java has been consciously oriented at C and C++ to simplify learning for programmers with knowledge of these popular languages and therewith to accelerate the spread of Java. The language provides the typical primitive data types for boolean, characters (char), integers (byte, short, int, long), and floating-point numbers (float, double), in which the different types of a category cover different ranges of values. In order to process many similarly structured data, arrays (or fields) with fixed limits are available. For other data types, Java offers a very extensive class library, e.g., for processing strings; managing data in stacks, lists, trees, or graphs; designing graphical user interfaces; or communicating in networks. In addition, there are numerous freely available class libraries on the net for a variety of purposes. To implement methods using algorithms, Java provides the usual control flow statements, with which elementary instructions can be composed. Elementary instructions are variable declarations with or without assignments, increments or decrements, method calls, or instance generations. Sequences of instructions can be formed for sequential processing. For the decision-driven execution of program parts, simple case distinctions with or without alternative

(if-then statement, if-then-else statement) or also with multiple alternatives (switch statement) are available. To control repetitions there are loops for iterating over a range of values (for statement) and over collections (for-each statement) as well as loops checking a condition before the execution of the loops' body (while statement) or after the execution (do-while statement). Program blocks belonging together are marked with curly braces ({...}). Both classes and methods can be defined using recursion. Constants and specifications can be combined in interfaces that are treated like classes; however they need classes for implementation. Classes and interfaces can be structured into semantically linked packages. A Java program then consists of a sequence of class definitions and interfaces, which can make use of the extensive Java class library and can, but not have to, be structured into one or more packages.

With Java, applications can be created, programs that can be executed directly with the Java interpreter, including apps for the operating system Android for mobile devices, and so-called applets, which are embedded in web pages and run, when a web page is displayed in a web browser. Applications need one single class to define a main method to indicate from where the program should start. Java supports all characterizing concepts of object-oriented development, as collected by Armstrong (2006), such as inheritance, object, class, encapsulation, method, method passing, polymorphism, abstraction, instantiation, attribute, information hiding, and dynamic binding (in descending order of use in definitions).

One of the main strengths of Java is that its programs can be run on all platforms for which an implementation of the Java virtual machine exists. This is the case, for example, for all relevant desktop operating systems. The reason for this is the goal of supporting network applications running on a variety of systems with different operating systems. To achieve this, the Java compiler generates a platform-independent object file format, which can then be executed in the respective Java runtime environment. The generated so-called bytecode is architecture-independent, but can be easily translated into machine code of the

executing machine and is thus efficiently executable. In order to allow the development of reliable programs, Java places great emphasis on the early identification of problems at compilation time (strictly typed language, compliance with class interfaces), loading time (testing of bytecodes), runtime (access to null pointers, violation of array limits), and the avoidance of error-prone situations. Therefore, language concepts such as pointer arithmetics, explicit reservation/release of memory, multiple inheritance in classes, and pre-processor statements were not included in the language design to simplify the development process. Because Java was designed for networked/distributed environments, great emphasis was also placed on security. Various security concepts have been implemented in order to prevent program manipulation by inserted parts. Applets from external servers are run in a closed environment (so-called sandbox). This prohibits access to the file system of the executing machine or the execution of programs and allows network access only to the source server. In the event of an infringement, the browser's security manager aborts the execution.

Java in the Educational Context

Java is widely used and omnipresent as a programming language not only in the field of software development as has been discussed in the former section but also in computing education at universities and secondary schools. At universities, Java is a popular language for the introduction into programming. To clarify the usage of Java in German universities, the authors conducted a survey in the first half of 2017. About 20% of those German universities responded where studying a subject related to computer science was possible. Regarding those universities, the proportion of universities for applied sciences vs. regular universities in our survey (69%:31%) was roughly the same as in the whole country (70%:30%). The geographic distribution of responses also adds to representativeness, since responses from 14 out of 16 states were gathered. Java was used in about 80% of

universities for teaching introductory object-oriented programming. Adding to that the number of cases where it is used in later advanced courses, usage of Java was reported in more than 90% of universities. Similar results could be obtained for upper secondary education, where it is frequently used as a text-based programming language after an introduction into programming with a block-based language (e.g., scratch, scratch.mit.edu) in middle schools. Regarding the spread of Java, there are national differences. In Germany, for example, Java is prescribed as the language to be used in central school-leaving exams of upper secondary schools in many of Germany's federal countries. The same formerly mentioned survey revealed that at least in upper secondary schools in half of all German states, Java was used as one of the text-based languages to teach concepts of object orientation. Of course, the spread in secondary education, higher education, and work life is linked: upper secondary education aims to prepare for future life situations by being practical and near to the learners' everyday lives and also for subsequent educational phases by following the principle of science propaedeutics. In higher computing education, too, programming languages are used, which are practically relevant for the graduates and which therefore create good job prospects. Because of its more than two decades ongoing development history, Java can be described as a mature programming language that implements the most important concepts of object-oriented programming in a neat way. Java's popularity and presence over a longer period of time have the consequence that there are numerous introductory and specialized textbooks and online offers such as tutorials or video courses available; in addition numerous research work on the development and testing of learning and teaching concepts for diverse target groups, pedagogically driven comparisons with other programming languages, empirical studies on learning difficulties and actions to avoid these, documented Java examples from various programming projects, and much more. There is also a wide range of freely available tools for Java programming from introductory integrated development environments with diverse visualizations up to

professional software development tools with integrated modeling tools and automated source code generation. The availability of all such resources on the WWW supports the learning of the language, and on various platforms, there is fast help for Java questions of any kind.

In secondary schools, Java has spread since the second half of the 1990s. The first documented teaching examples were often characterized by the attempt to implement imperative problem solutions using Java. Over the years, however, numerous high-quality teaching materials (e.g., school textbooks) have been published. In addition, various tools and learning environments have been developed over the course of time, which are apt to support teaching. The availability of such systems can, on the one hand, be seen not only as a strength with regard to instructional usage but also as an indicator of potential learning difficulties with regard to the language, since otherwise learning would be possible without such systems.

Among the systems for education, BlueJ (bluej.org) is a simple and compact programming environment for Java, which supports programming beginners through appropriate visualization of ideas of object orientation. For this purpose, the user is presented, for example, a visualization of the class structure, via which objects can be instantiated, which are then displayed in an object bar. These objects can then be inspected, and their methods can be executed including input of parameter values. BlueJ is therefore often used as an introductory programming environment for Java. Also noteworthy is Greenfoot (greenfoot.org), a widely used learning environment for Java. It can be used to create simple two-dimensional graphical applications. In certain scenarios, the learner is provided with basic functions, which can then be expanded step by step. Particularly interesting is the development of Stride in Greenfoot, a Java-based form of block-based programming. Learners who previously learned to use a block-based programming language can use it to create programs that are block-based, which makes the transition easier. The source code fragments assigned to these blocks can then be developed further on source code level. This allows a connection to didactic

concepts for younger learners. There have been also experiments with such interface concepts concerning subsequent educational phases. Thus, an earlier version of the professional programming environment Netbeans was able to open BlueJ projects, thus simplifying the transition from an educational to a professional programming environment. The corresponding plugin, however, is not being further developed.

Because of its spread in the field of education, other successful and tested educational environments have been adapted so that they can be programmed with Java, and existing learning and teaching concepts can be reused. Among them are Turtle, Karel The Robot, Lego Mindstorms, Arduino, and others. In addition, a number of didactic class libraries have been developed that simplify or support Java's not very intuitive input and output and teaching concepts based on it.

Programming Languages for Secondary Schools, Python

Michael Weigend
Holzkamp Gesamtschule, Witten, Germany

Python is a high-level multipurpose programming language created by Guido van Rossum and first released in 1991. Python is open source and managed by the nonprofit Python Software Foundation (<https://www.python.org/psf/>) since 2001. Python is taught in secondary schools in many countries and is the most popular introductory programming language at top US universities (Gua 2014).

Python supports multiple programming paradigms, including object-oriented, imperative, and functional programming. There exist two versions of Python, which differ only in a few details but are not compatible, the original Python 2 and (since 2008) Python 3. All source code mentioned in this contribution is written in Python 3.

This contribution presents Python from an educational perspective, focusing on these two questions:

- In which way does Python support individual learning by experimenting and exploring?
- How can programming with Python help to develop high school student's computational thinking skills?

Computational thinking is an activity that is associated with problem-solving using a computer. It “represents a universally applicable attitude and skill set everyone, not just computer scientists, would be eager to learn and use” (Wing 2006, p. 33). Selby and Woollard (2013) identified five basic facets of computational thinking: algorithmic design, abstraction, decomposition, generalization, and evaluation. These five concepts are used as a framework for the presentation of Python language features.

Experimenting and Exploring

The Python Shell

In the interactive Python Shell, learners can try out single Python commands. Python Shells are available on the Internet and can be used online (e.g., <https://www.python.org/shell/>).

A very common way to work with Python in the classroom is to use the integrated development environment IDLE (integrated development and learning environment). IDLE is part of the standard distribution, which is available for free and can be downloaded from the official Python website (<https://www.python.org>).

The Python Shell displays a command line starting with the prompt `>>>`. When a user enters a Python statement and hits the ENTER key, the Python runtime system interprets the

statement and returns the result in the following lines (read-eval-print loop, REPL). Examples:

```
>>> 12 * 17
204
>>> round(12.34)
12
>>> 1 < 2
True
```

Introspection

Python supports exploring objects and classes by introspection. Each object has introspective attributes that begin and end with double underscores. These attributes make it possible to look inside objects.

Example: All classes have the attribute `__bases__` containing a tuple with all base classes the class is derived from. For example, the standard class `int` (integer numbers) is derived from the most abstract class `object`:

```
>>> int.__bases__
(<class 'object'>,)

```

There are some built-in functions for introspection. The function `type()` returns the class an object is an instance of:

```
>>> type(1)
<class 'int'>
```

The function `id()` returns the identity (a unique integer number) of an object.

```
>>> id(1)
496855168
```

Experimenting and Inductive Learning

Experiments are the basis of scientific knowledge acquisition. Inspired by observations researchers develop theories (models) about the world.

In an inductive teaching pattern, students try out function calls in the Python Shell first and verbalize an abstract definition of the effect of the function after this phase of experimenting.

Task: “Try out the following statements. Explain what the function `len()` calculates.”

```
>>> len([10, 4, 12])
3
>>> len("Washington")
11
>>> len([None])
1
>>> len("")
0
>>> len(3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object of type 'int' has no len()
>>> len([])
0
>>> len([[1, 2, 3]])
1
```

Experimenting in the Python Shell can help clarifying difficult concepts and avoiding misconceptions. For example, the idea of identity and the difference between mutable and immutable objects can be explored.

In Python, numbers are immutable objects. What is the effect of these two assignments?

```
>>> a = 1
>>> b = 1
```

Now there are two names (`a` and `b`) for the one and only object 1. This can be verified by checking the identities:

```
>>> a is b
True
>>> id(a)
1494706304
>>> id(b)
1494706304
```

In contrast to numbers, Python lists are mutable objects. They can change their states.

```
>>> s1 = [1, 2]
>>> s2 = [1, 2]
```

These two assignments generate two equal but not identical objects:

```
>>> s1 is s2
False
>>> s1 == s2
True
```

Abstraction: The Python Type Hierarchy

Computer programming includes abstraction. The programmer considers only those aspects of a scenario which are relevant with respect to the purpose of the project and ignores unimportant details (Fig. 1).

Programming Languages for Secondary Schools, Python, Fig. 1 An excerpt from the Python type hierarchy

$G = (V, E)$
 $V = \{1, 2, 3, 4\}$
 $E = \{(1, 2), (1, 3), (2, 1), (2, 3), (2, 4)\}$

Programming Languages for Secondary Schools, Python, Fig. 2 A directed graph with four vertices and five edges

Python standard types (built-in types) and corresponding operations provide a framework for modeling. For example, a Python list is a mutable sequence of items that can be objects of any type. Lists are used to model collections that can change their size. On the other hand, a Python tuple is an immutable sequence of items and may be used to model an entity that consists of a fixed number of elements. For example, a group of persons may be modeled by a list of tuples, each tuple representing name and age of a person (Fig. 2):

```
group = [("Anna", 16), ("Tom", 15),  
        ("Svenja", 15)]
```

A directed graph can be modeled by a Python dictionary, mapping each vertex to a list of adjacent vertices, for example, {1: [2, 3], 2: [1, 3, 4], 3: [], 4: []}.

Algorithmic Design and Basic Python Syntax Features

A program is an *implementation* of an algorithm that runs on a computer. It is also a verbal *representation* of an algorithm that is to be read and understood by humans. This section presents a few basic language features that help to increase the readability of Python source code.

Layout

The layout of a Python script has a semantic meaning. A block of statements is not defined by curly braces as in Java but by indentation. Lines of

code that start with the same number of leading whitespaces belong to the same block. The following script prints the first ten Fibonacci numbers. It consists of two blocks. (Comments start with a hash character # and are terminated by the end of the line.)

```
# Fibonacci numbers
a = b = 1           # first line of block 1
for i in range(10): # second line of block 1
    print(a)         # first line of block 2
    a, b = b, a + b  # second line of block 2
```

A statement is terminated by the end of the line.

Multiple Assignments

Multiple names can be assigned to an object in one single statement:

```
a = b = 1
```

It is also possible to bind multiple names to multiple objects in one single statement. For example,

```
a, b = 1, 2
```

has the same effect as

```
a = 1
b = 2
```

Swapping values can be implemented very intuitively:

```
a, b = b, a
```

Mathematical Conventions

Instead of individual comparisons that are connected by a Boolean and operation, like $(a < b) \ \&\& \ (b < c)$ in Java, Python programmers can use chained comparisons like $a < b < c$. This is a common convention in mathematics and makes conditions shorter and easier to comprehend.

```
if 18 < age < 60:
    print("The entrance fee is 10 EUR.")
else:
    print("The entrance is free.")
```

In mathematics there is a special notation for defining sets (set builder notation) using an output expression (e.g., $2 \cdot x$), a variable (e.g., x), an input set (e.g., $\mathbb{N}$), and a predicate (e.g., $x^2 > 3$). Example:

$$A = \{2 \cdot x | x \in \mathbb{N}, x^2 > 3\}$$

In Python a similar notation, which is called *set comprehension*, can be used.

```
A = {2*x for x in {1, 2, 3, 4, 5} if
x**2 > 3}
```

The same concept is used for lists (mutable sequences). List comprehensions allow to write sophisticated algorithms like Quicksort in a concise way focusing on the algorithmic idea.

```
def qsort(s):
    if s == []:
        return s
    else:
        pivot = s.pop()
        left = [x for x in s if x <= pivot]
        right = [x for x in s if x > pivot]
        return qsort(left) + [pivot] + qsort(right)
```

Assignments and Dynamic Typing

In Python an assignment has a slightly different meaning than in C or Java. The statement

```
a = 3
```

means that the name *a* is bound to the object 3. An intuitive metaphor to visualize this is putting a sticky note with a name to an object.

In Java it would be necessary to declare the variable first. That means to connect the name “a” to a type, for example, integer. Only after this declaration it is possible to assign this name to an object.

```
int a;
a = 3;
```

Programming Languages for Secondary Schools, Python, Fig. 3 Typing in Python (on the left) and Java (on the right)

In contrast, Python adopts dynamic typing (“Duck Typing”). A name is connected just to an object but not to a type. However, objects are not “untyped” but they are per se connected to types (Fig. 3).

In Python, a literal representing an object of a certain type must be constructed according to certain grammar rules. So it is possible to recognize the type just by “looking at the literal.” For example, an integer number (in decimal notation) must start with a digit 1..9, followed by a sequence of digits 0..9 of arbitrary length.

Optional explicit typing is possible in Python since version 3.5.

Decomposition: Functions

Decomposition – breaking down complex problems by functionality – is considered to be a major facet of computational thinking (Selby & Woollard 2013). Defining functions usually is the first method of decomposition that students learn in a programming class. For example, a long sequence of instructions can be decomposed into definitions of functions and a “main program” consisting of function calls.

In Python a function is created by a `def` statement. Example:

```
def area (width, height):
    return width * height
```

If a `return` statement is missing, the function returns the empty object `None`. A function may be called with positional arguments:

```
>>> area(13, 10)
130
```

Another method of passing data is keyword arguments:

```
>>> area(width=13, height=10)
50
```

If meaningful names are used, keyword arguments can improve the readability of the function call by making it more explicit.

Generalization

In the context of program development, generalizing is the ability to recognize already existing pieces of software from previous projects that can be reused in new projects to solve new problems.

The Python Type Hierarchy

The Python type hierarchy illustrates the cognitive advantage of generalization. Operations are “as general as possible” and can be used for as many types of objects as possible.

Any object of a standard type can be tested for truth-value. “Empty” objects like 0 and collections with zero elements like an empty list [] are `False`. Nonempty collections and all numbers that are not 0 are `True`. This property can be used to write short conditions (line #1):

```
s = [3, 2, 32]
while s:
    x = s.pop()    #1
                  #read and remove the last
                  #element from s
    print(x)
```

Output:

```
32
2
3
```

Collection types include lists, tuples, strings, sets, and dictionaries. Objects of these types have common properties: They contain elements (items) and they are iterable. Any collection can be tested for membership of an object in the same way using the `in`-operation:

```
>>> 1 in [1, 2, 3]
```

```
True
>>> "I" in "team"
False.
```

The items of any collection can be iterated in a for-instruction:

```
>>> for ch in "sun":
    print(ch)
```

```
S
u
n
```

Objects and Classes

Object-oriented programming (OOP) supports generalization in several ways including overloading and inheritance. An object-oriented program is a system of objects that interact by sending and receiving messages. The program might be considered as a model of a piece of reality, say a library or a bank. In contrast to scientific models (e.g., atom models), the primary motive for creating an object-oriented program is not getting a better understanding of reality but creating a system that is easy to understand and to maintain. The following Python statement defines a class modeling traffic light with four states.

```
class TrafficLight:
    states = ['red', 'red yellow',
              'green', 'yellow']    #1

    def __init__(self):            #2
        self.index = 0

    def change(self):              #3
        if self.index < 3:
            self.index += 1
        else:
            self.index = 0
        return self.states[self.index]
```

Comments:

#1: This statement defines a class attribute. It is a list, representing the sequence of states of a European traffic light. Class attributes do not represent properties of individual objects but properties of all objects of the class.

#2: The name `__init__` is reserved for the constructor method of a class. The first parameter – usually called `self` – refers to the instantiated object. All methods must have this first parameter.

Students can develop a class definition with the standard Python editor IDLE and then store the source code as a file, for example, under the name `traffic.py`. This file is called a module. To test the class, a student may run the module in the IDLE environment. The Python Shell is then restarted. The student may create an instance of the class and try out method calls on the command line of the shell:

```
>>> t = TrafficLight()
>>> t.change()
'red yellow'
>>> t.change()
'green'
```

Modules

The class defined in the module can be imported and then used by another module. Example:

```
from traffic import TrafficLight
t = TrafficLight()
for i in range(4):
    state = t.change()
    print(state)
```

```
Output:
red yellow
green
yellow
red
```

P

Overloading: Adopting Familiar Concepts

One method of generalizing is to use familiar concepts in new domains. For example, people are familiar with different types of addition since kindergarten. We can add numbers, strings, lists, physical sticks, etc. These are all different operations implementing one and the same abstract idea of “putting things together.”

In Python operators and built-in functions can be overloaded by defining “magical” methods with certain names starting and ending with two underscores. The following Python statement defines a class modeling physical length. It

illustrates the overloading of the plus operator. An instance of this class represents a length or spatial distance through a float number and a unit like cm or ft.

```
class Length:
    meter = {'mm': 0.001, 'cm': 0.01, 'm': 1,
             'in': 0.0254, 'ft': 0.3048} #1

    def __init__(self, value, unit):      #2
        self.value = value
        self.unit = unit

    def getMeter(self):                  #3
        return self.value * self.meter[self.unit]

    def __add__(self, other):            #4
        s = self.getMeter() + other.getMeter()
        return Length(
            s/self.meter[self.unit], self.unit)

    def __repr__(self):                  #5
        return str(self.value) + ' ' + self.unit
```

#1: This class attribute is a dictionary mapping units to the number of meters they represent. For example, 1 mm is equal to 0.001 m.

#2: A length object has two attributes, representing the numerical value and the unit of a length description.

#3: This method returns the numerical value of the length in meters.

#4: This method adds two length objects and returns a new object of the same type representing the sum. This new object has the same unit as this object.

#5: This method returns a printable representation of the object, like '15 cm'.

Defining a method named `__add__` means overloading the plus operator. Each time the Python interpreter evaluates an expression like `a + b`, it sends a message like `a.__add__(b)` to object `a`. In the same way, the developer can define further operations, including subtraction, multiplication, division, or Boolean functions like `<`, `>`, and `==`.

The class definition can be tested in the Python Shell. Example:

```
>>> Length(2, "cm") + Length(2, "in")
7.08 cm
```

Inheritance

Inheritance is a special form of reuse. A specialized class is derived from a more general base class. Instances of the derived class have all the attributes and methods of the base class plus additional attributes and methods. The following example illustrates how to derive a class modeling directed graphs from a Python dictionary.

```
class Graph(dict):                        #1
    """ Modelling a directed graph """

    def __init__(self):                  #2
        dict.__init__(self, {})

    def insertVertice(self, v):
        if v not in self.keys():
            self[v] = []

    def insertEdge(self, v1, v2):
        if (v1 in self) and (v2 in self) and \
            (v2 not in self[v1]):
            self[v1].append(v2)
```

Comments:

#1: The name of the base class (`dict`) is mentioned in parentheses.

#2: A new graph object is instantiated as an empty dictionary `{}`.

Students may create this program text using IDLE, store, and execute it. Then they can try out the new class in the shell window:

```
>>> g = Graph()
>>> g.update({1: [2, 3], 2: [1, 3, 4],
3: [], 4: []})
>>> g
{1: [2, 3], 2: [1, 3, 4], 3: [], 4: []}
>>> g.insertEdge(4, 3)
>>> g
{1: [2, 3], 2: [1, 3, 4], 3: [], 4: [3]}
>>> 1 in g
True
```

This dialog illustrates the advantages of inheritance: One can (re-)use methods that are inherited from the class `dict`. For example, one can extend a graph using the dictionary method `update()` and

print a representation of the graph using the “magical” method `__repr__()`.

Evaluation: Tracing and Asserting

A further facet of computational thinking is the ability to evaluate the efficiency and correctness of algorithms. This is a “high-level activity” that is not necessarily part of programming in the sense of implementing an algorithm. However, in “defensive” programming techniques, the possibility of bugs is considered already during the developing process. The programmer builds in certain protection mechanisms that make verification and error detection easier. Python supports tracing, test-driven development, and assertions.

Tracing

Normally, a python program runs in the “debug mode.” In this case the system variable `__debug__` has the value `True`. If the interpreter has been started with the `-O` option, it is executed in the “optimize mode.”

```
$ python -O myscript.py
```

In this case `__debug__` is false. The variable `__debug__` can be used to design a program, which explains to a human being how it works (tracing) in order to convince her or him that it is logically correct. The definition of a self-explaining Quicksort function may start like this:

```
def qsort(s):
    if __debug__:
        print("I am sorting", s)
    ...
```

Assertions

Python provides a feature for testing assertions, the `assert` statement. It consists of the keyword `assert` and a logical condition. Example (testing a precondition):

```
def area (width, height):
    assert (width > 0) and (height > 0)
    return width * height
```

During runtime (in debug mode) each `assert` statement is evaluated. If it is true, nothing happens. Otherwise the interpreter raises an exception.

Assertions can be used to check pre- and post-conditions. They may help to understand difficult algorithms (like Quicksort) because they relate complex concepts to simple (and intuitive) implications. For example, it is intuitively clear that sorting a list does not change the number of element.

Test-Driven Development: Doctest

The Python standard module `doctest` supports test-driven development (Beck 1999). When a programmer defines a function or a class, she or he can add a string at the beginning of the instruction block documenting the code like a comment (docstring). The docstring of a function can be used to define test cases by writing function calls and the expected results like in an interactive Python session. Consider a module containing a Quicksort function:

```
def qsort(s):
    """ Returns a sorted list of all
    elements of s.
    >>> qsort([2, 1])
    [1, 2]
    >>> qsort([])
    []
    """
    ...
```

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

In this example the docstring specifies two test cases. The first test case can be read “`qsort([2, 1])` must return `[1, 2]`.” If the module file is run directly (and is not imported), the last two lines of codes are executed, and the doctest system is activated. If the module is imported by another module, the docstring is ignored.

If one of the expected results differs from the calculated result, doctest raises an exception. If nothing happens, the function works fine for all test cases.

C#; C++; FORTRAN; Java; Python

Introduction

University computer science (CS) and information systems (IS) departments are under constant pressure to adapt various programming languages for their courses: Local software companies want graduates to be trained in whatever web development, scientific computing, firmware, or high-performance computing language they are using. Other companies want coders to maintain their legacy systems in COBOL or FORTRAN. Engineering and science faculty may want the introduction to computer science programming course taught in whatever programming language they use in their labs. Finally, CS and IS faculty want their students to learn how to code.

What Do Programming Languages Need to Provide for University Courses?

The first two courses in CS and IS curricula are Introduction to Programming I and II (CS-I and CS-II), the objectives of which are to teach basic programming concepts and creative problem-solving skills. The choice of programming languages in these courses first and foremost must facilitate these goals. The *structured* and *imperative* programming paradigms (Dijkstra 1975; Salus 1998) include the essential CS-I and CS-II concepts of data types, variables, arithmetic expressions, type conversion, if then else, for and while loops, strings, character storage (e.g., ASCII/Unicode), pass-by-value/reference parameters, run-time stack, and heap memory management concepts. The *object-oriented* programming paradigm (Salus 1998) also must be taught in both CS-I and CS-II. It includes classes, class instances, references, inheritance, constructors, class-level variables and properties, destructors, and simple dynamic memory management. More advanced CS and IS courses will need to teach the use of a few built-in classes implementing important data structures such as lists, stacks, and queues, as well as file and database access.

Beginning programming students also must learn how to creatively develop algorithms to solve new problems (Soloway 1986; Lister 2011). Writing code is a creative endeavor akin to composing music. A music composition class exposes students to classic examples of music like a Bach fugue or a funk beat and then requires them to creatively write new music. In the same way, the beginning programming class exposes students to classic algorithms such as the bubble sort or a linear search. Then students are expected solve different problems by creatively adapting the techniques in these classic algorithms to new situations. Traditionally, CS-I and CS-II include sorting, searching, and other basic algorithms (e.g., Kunth 1968).

Beginning programming students need to learn *hierarchical decomposition* (Yourdon and Constantine 1975). Even small programs of only 50,000 lines of code are unfathomably complex.

In the same way that the writer of a long research paper needs an outline to keep track of the paper's organization, coders need to learn how to break apart and organize their code. "Hierarchical decompose" is when the coder breaks up a complex problem into tiny sub-components. These tiny components are then developed as individual functions or classes and finally assembled into an "outline" that implements the complete solution. The structured programming paradigm divides large programs into small procedures or functions. The object-oriented paradigm additionally divides programs into classes. CS and IS students need to understand and use both of these hierarchical decomposition approaches.

One of the key aspects of the functional programming paradigm (Salus 1998) is the use of small, isolated "recursive" functions that are defined in terms of themselves. Recursion is another key coding skill that is essential for computer scientist students, as many algorithms and data structures are inherently recursive. Virtually any modern industrial programming language supports recursion and the functional paradigm. Figure 1 shows a recursive function implementing factorial. Note that it does not have any loops and it calls itself.

Programming students need to learn good *programming style* (Yourdon and Constantine 1975) which is an essential aspect of structured programming. Good style allows programmers to understand each other's code, facilitating debugging and modifications. Following many of the concepts developed in the structured programming movement, precise variable and function names are essential, allowing everyone on the team to understand what a function is intended to do and precisely what each variable contains. A good block comment needs to be

```
int fact(int n) {  
    if(n==1) return 1;  
    return n * fact(n-1);  
}
```

Programming Languages for University Courses,
Fig. 1 Recursive function implementing factorial

included at the top of each class or function (sometimes called a procedure, method, or subroutine). This block comment needs to include a single sentence describing the purpose of each class or function.

While not essential, it helps if beginning programming courses are fun and seem relevant. Key programming concepts and algorithms can be taught using *simple graphics* and often provide additional motivation for students. *Event-driven programming* allows students to see how their coding skills can rapidly create applications similar to those they use on their laptops and cell phones.

While computer science, information systems, and other engineering and science students are generally fairly computer savvy, a good programming language needs a helpful *integrated development environment* (IDE) for constructing, running, and analyzing code. The environment should be easy to install on virtually all laptops and home computers. It should be available to students for no cost. It should be easy to use and should facilitate learning how to code. Suitable development environments provide helpful error messages assisting students in locating syntax errors and helping them understand the causes of run-time bugs. A superb debugger is essential as it assists students in observing the code running, allowing them to see "inside" their code to better understand why bugs are occurring and what needs to be done to fix them.

Some have argued that an IDE explicitly designed for beginning programming students may be superior to an industrial tool such as C#'s Visual Studio or Java's NetBeans. However, we have found few disadvantages to these industrial tools for successful CS and IS majors and minors, and since these tools must be learned eventually in the workplace, we see little advantage in not introducing them early in the CS and IS curricula.

Industrial Versus Educational Languages.

The objective of university computer science (CS) and information systems (IS) programs is to *educate* students in key concepts and skills, not to *train* them to use all the features of particular industrial languages. Industrial programming

languages necessarily must include vast collections of built-in classes and other features for implementing complex data structures, file and database access tools, etc., features that are far beyond the scope of academic programs. Such advanced language features need to be learned on the job or through industrial boot camps.

However, fairly broad subsets of industrial programming languages such as Java, C#, C++, or Python allow CS or IS departments to provide solid coding pedagogy while creating sufficient skills with current industrial tools to allow students to obtain summer and part-time internships while in school and to function effectively in initial job settings. If an industry-popular language can provide the same educational experience as an academic-focused language, we suggest the industrial language is a better choice.

Academic CS or IS programs only have a limited amount of time to cover too many important subjects, and each additional programming language takes weeks of class time that could be used to teach additional skills. We suggest using a minimal set of currently popular, industrial programming languages that cover the needed educational paradigms, topics, and skills.

Which Programming Languages Are Best for CS-I and CS-II?

While virtually any modern industrial object-oriented programming language will allow the CS or IS instructor to teach CS-I and CS-II, some languages are much better than others for more advanced CS and IS courses.

C++. One of the top industrial programming languages is C++, particularly for low-level operating systems and firmware coding, as well as high-performance computing. However, the object-oriented programming concepts in C++ were added to the C language fairly early in the object-oriented movement, and these C++ object-oriented programming (OOP) features are somewhat arcane. Subsequent OOP languages such as Objective-C, Java, and C# correct many C++ shortcomings. Further, C++ has many “sharp”

```
int x = 3;
if (x=4) cout << x;
```

Programming Languages for University Courses, Fig. 2 Common C++ beginning programming bug. Outputs the integer 4

corners that can create complex bugs for beginning programming students. Figure 2 shows a common beginning programming bug or “sharp corner” caused by the use of “=” rather than “==.” Most programming languages do not allow an assignment statement to be used where a Boolean expression is expected or allow the integer side effect of that assignment statement to be used as a Boolean. Further, C++ uses pointers that contain actual memory addresses creating potential security issues, and C++ does not check array and string boundaries. Finally, C++ does not do much if any memory management of dynamically created class instances potentially causes memory leaks. Memory management thus must be taught at the same time as classes, making a complex topic more difficult.

It is not hard to transition from Java or C# into C++, and CS and IS students need to learn these other languages anyway. In our opinion, it is better to delay learning C++ until more advanced programming courses so students can first learn solid programming skills with a programming language with fewer “sharp corners.”

Java. Java is a solid choice for CS-I and CS-II and is used by many universities. Along with C#, Java is one of the top choices in the industry for application coding. Its syntax is similar to C++, but it has cleaned up virtually all of the C++ shortcomings, including multiple inheritance and memory management issues. It has fairly strong typing, forcing students to have to do explicit type conversion (e.g., typecasting), for example, converting a real number into an integer or string. While requiring a bit more work for the student, strong typing eliminates many hours of debugging and insures the students understand the underlying variable type and

arithmetic issues. A number of free IDEs (e.g., NetBeans) are available for Java that run on virtually all laptops and PCs.

There are some negatives with Java however. While event-driven programming with buttons, textboxes, list boxes, and the like is available in Java, they are a bit too complex for students to use in a CS-I course. We are also not familiar with any free high-quality automatic class diagramming tool for Java, the lack of which makes it more difficult to teach complex object-oriented design in CS-II. Java generally is not going to generate code that runs as fast as C++ making it less than ideal for high-performance computing courses, and it lacks a number of features making it less than ideal for a CS operating systems course.

C#. Microsoft created C# as its version of an object-oriented application programming language using C syntax and, in the process, avoided many of the problems with C++ and some of those with Java. C# is one of the most popular programming languages and an excellent choice for CS-I and CS-II. (We bundle both C# and Visual Basic under C#'s popularity as they are virtually the same, except C# uses "C" style syntax.) C# is a very "clean" language with which to teach CS-I and CS-II. It is strongly typed which helps students better understand arithmetic type conversions and casting operations. The Visual Studio Integrated Development Environment (IDE) is one of the best, and its debugger has no equal. There is a free automatic class diagramming tool within the IDE that can really help students visualize and understand complex OOP systems. C# and its IDE allow development of web and mobile applications, facilitate clean database interaction, and have a wide range of additional libraries available. The IDE provides excellent memory management of dynamically created class instances, allowing this topic to be taught separately from a student's initial exposure to classes. While not as fast as C++, its run-time environment can generate fairly fast code that is more than adequate for most situations.

Because C# is controlled by Microsoft, new coding concepts only come from their development teams, and generally they are very cleanly

thought-out and constructed. Microsoft provides C# and the Visual Studio software to universities and their students for free. And there are virtual machines that allow C# to run on Apple MACS and Linux machines. However running a virtual machine or dual boot Windows 10 on an Apple MAC can be a bit complex for some beginning programming students, and other solutions for running C# on non-Windows machines can be less than optimal. Finally some students and faculty are uncomfortable with learning and using proprietary languages.

Python. Python is an interpreted programming language that uses indentation to visually indicate blocks rather than traditional brackets in the C family of languages or Pascal's "Begin End" blocks. Python is a language that is designed to hide a great deal of what lies under the surface, allowing coders to stay focused on the algorithms being implemented. Python uses weak or dynamic typing or arithmetic, automatically converting between variable and expression types. While arguably less than ideal for students planning on majoring in engineering, science, CS, or IS who need to be exposed to lower-level issues in CS-I and CS-II, it might be better for a more general purpose survey of programming course. Some traditional CS-I data structures, such as arrays, are not implemented in Python, making it difficult to teach these concepts which CS, IS, engineering, and science students subsequently will need to learn if they are to transition to C++ or another more conventional programming language. Python has seen significant use in industry. Open-source IDEs and run-time environments are available as well as easy-to-use graphics packages that can be incorporated into CS-I and CS-II curricula.

Legacy Programming Languages. There is considerable legacy code still being used in industry including FORTRAN and COBOL. Occasionally someone from the industry will want a university to train its students to use these languages. Generally this is not ideal, and these languages should certainly not be used in early CS or IS courses; No CS or IS faculty will want to teach CS-I or CS-II using GOTO statements

(e.g., Dijkstra 1968) which are at the heart of FORTRAN and COBOL legacy systems. Essential CS-I and CS-II object-oriented programming concepts need to be covered in Modern OOP languages such as Java. Each new programming language requires weeks of class time to just barely scratch its surface, so any classroom time spent teaching legacy languages is time not spent covering data structures, algorithms, and other essential topics.

What Programming Languages Are Best for Advanced CS and IS Courses?

While choosing a programming language or languages for CS-I and CS-II is the critical initial decision, some subsequent CS and IS courses will require additional languages.

Systems Programming. C++ is the standard CS programming language for building operating systems and – along with C – for computer engineers writing firmware. C++ code is also very fast, making it the clear choice for high-performance computing. CS students *must* learn C++, as it is the clear choice both for a senior level operating system course and possibly for an earlier systems programming course that covers pointers and bit manipulation including shifts, masking, and bitwise “and” and “or.”

Assembly. While professional computer scientists will rarely write a line of assembly, they may write compilers which generate assembly or machine code, and they need the understanding of computer architecture that is best developed by writing some assembly. Writing assembly and building compilers allow the computer scientist to understand how their C++ or other high-level language code is compiled and thus how it needs to be changed to make it run faster. The particular assembly is not that critical: A number of teaching assemblies are available that work well. Alternatively, a small focused subset of an industrial assembly can be used.

Engineering and Science Programming. Numerical analysis, Monte Carlo simulations, or other mathematical modeling may require specialized high-performance programming languages.

Engineers, math majors, and others may want to learn C++ in a systems programming course taught after CS-I or CS-II or as part of a high-performance computing course.

Specialized Application Programming and PHP. Information systems students must learn how to build web and mobile client and server-side applications as well as learn how to build and access a relational database from code; computer science students almost certainly should as well. Both Java and C# are excellent for applications development. However, information systems must develop HTML and JavaScript skills. PHP is a highly specialized programming language used to develop web applications. A PHP web development course should be required for IS students and be an elective for CS majors.

Programming Misconceptions at the K-12 Level

Monika Mladenović¹, Žana Žanko² and Ivica Boljat¹

¹Faculty of Science, University of Split, Split, Croatia

²Elementary school “Mejaši”, Split, Croatia

Synonyms

Block-based programming languages; K-12 novices; Misconceptions; Programming; Programming context; Text-based programming languages

Overview

As computing today is included in many fields, there are many efforts, by science or national communities, to engage K-12 students in programming through national curriculums, many movements, and new programming tools. However, teaching introductory programming is not as successful as we would like it to be. Various assessments of student knowledge reveal flawed understandings of the taught concepts, which we call misconceptions. Misconceptions in programming refer to incorrect models of some programming concepts. Despite the emergence of a plethora of new programming languages, students experience the same or similar misconceptions as they did more than 30 years ago. Identifying misconceptions can be crucial to minimize or even prevent misconceptions for both teachers and students alike. Over the last few decades, numerous researchers have classified different types of misconceptions and the problems they cause when novices try to learn to program. Most studies about misconceptions are conducted at the undergraduate or graduate level using text-based programming languages, while there is a lack of similar researches at the K-12 level. As K-12 students are in the early stages of cognitive development and have fewer preconceptions than undergraduates or graduates, it is

reasonable to expect that they are not facing the same difficulties.

With the development of visual block-based programming languages, such as Scratch, designed for the younger generation of programming novices, there is a new scope of possible additional misconceptions and/or possibility to minimize known misconceptions. In comparison to the text-based programming languages, block-based programming languages have the advantage of eliminating syntax problems thus allowing students to focus on problem-solving instead of syntax. Besides focusing students on problem-solving, block-based programming languages offer new programming context like programming games, storytelling, animations, and other. Block-based programming languages enter into all educational levels (Mladenović et al. 2016a), but the most sensitive age group are K-12 programming novices. When educating K-12 programming novices' teachers should consider: students' age, the programming language used, the programming context, and the programming concept learned.

How do the above-mentioned new programming settings effect on misconceptions at the K-12 level? To answer the question posed, diverse aspects should be considered: (a) misconceptions developed by the K-12 students should be identified; (b) the impact of different programming settings on developing misconceptions should be detected. By considering mentioned aspects, educators should offer different teaching approaches for the basic programming concepts, like variables, sequencing, and repeating, to minimize or even prevent programming misconceptions.

K-12 Novices and Programming Languages

The term “programming novices” is mostly referred to the undergraduate students. What about K-12 programming novices? Abstraction skills are essential in programming. According to Piaget, abstract thinking is at the last stage of cognitive development in the formal operational stage (Piaget 1952). Therefore, K-12 children (7–11 years) are mostly at the concrete or pre-

formal stage of cognitive development while undergraduates are matured in logical reasoning (Sekiya and Yamaguchi 2013). Accordingly, the problems for many students start at an early stage of learning when they need to understand and apply the abstract programming concepts. Teaching K-12 novices should involve teaching and learning strategy that begins with the concrete in a context familiar to students and then gradually leads to an understanding of the abstract (Dann and Cooper 2009). Students understand what they can see, and if they cannot see what a program is doing, they struggle to understand it. The question we should ask is: How can we make abstract programming concepts concrete?

Novices programming languages should have simple syntax simplifying the learning process but at the same time a powerful means to introduce students to programming. Such programming languages are called mini-languages (Brusilovsky et al. 1997). The learning focus should be on language semantics not on the syntax itself.

Logo and BASIC are both considered one of the first micro-languages but with the different underlying philosophies. The Logo programming language is primarily designed to introduce children to programming, based on the constructivism approach, while the BASIC programming language is intended to be a teaching tool for undergraduate students and everyone interested in microcomputers. Many new programming languages arise from these two programming languages but with different approaches and goals.

Based on the programming language syntax, programming languages for K-12 novices could be classified into three groups: visual-text-based programming languages, procedural-text-based programming, and visual-block-based programming languages.

Visual Text-Based Programming Languages

“Turtle graphics” of Logo programming language (Papert 1980) is considered as one of the first mini-languages. The programming language Logo, created in the late 1960s, is based on the idea of the microworlds where the student, as a programmer, is controlling the actor in the microworld. The actor can be turtle, robot, sprite, and so on. The

main characteristic of such languages is the graphical output of the program execution in the form of, for example, moving the actor in the microworld.

Characteristic of the visual text-based programming languages is simple text-based syntax with the visual output of the program execution, usually represented in the microworld. Those languages are appropriate as the first steps in learning programming for children. As the “Turtle graphics” of Logo was one of the first such programming languages, the presented idea is widespread, so even Python contains the *Turtle library*, allowing using *turtle graphics* when programming in Python, as in the Logo programming language.

Programming context of the visual text-based programming languages is usually geometry but through concrete experience in the form of drawing different shapes by controlling the actor in the microworld. The visual output of the program execution allows students concrete to abstract experience because the execution of the text-based instructions is visible by moving the actor in the microworld.

Procedural Text-Based Programming Languages

The Logo programming language, a dialect of Lisp, was designed as a tool for learning. The name Logo derives from the Greek logos, meaning word or thought. In the same period of the Logo creation, the BASIC programming language also emerged. With the arrival of the microcomputers in the mid-1970s BASIC (an acronym for Beginner’s All-purpose Symbolic Instruction Code) started to become more popular. BASIC is text-based programming languages with textual input and output of the program execution. The original BASIC language is designed to facilitate students in fields other than science and mathematics to use computers.

BASIC could be considered as a predecessor of modern, similar programming languages. Nowadays, Python is more often used as a programming language for beginners because of the simple syntax and the increasing commercial popularity.

Programming context for procedural text-based programming languages is still based on

solving math problems such as arithmetics. As program input and output are text-based, abstraction is necessary to understand applied programming concepts.

Regardless of their simplicity, text-based languages are perhaps not suitable for the K-12 level students.

Visual Block-Based Programming Languages

In the last two decades, the new generation of the programming languages, designed for children, appeared. They all share the “Logo” philosophy (Papert 1980) with introducing the programming through microworld, representing the concrete manipulable world. The main difference, compared to Logo, is the visual, block-based input, where instructions are usually represented in the form of puzzles.

Characteristic of the visual block-based programming languages, such as Scratch, Alice, Blockly, Micro: bit, and so on, is manipulation with the visual objects on the screen instead of writing text instructions which is characteristic of text-based programming languages. Therefore, it is suspected that block-based programming languages require a concrete level of cognitive development while text-based programming languages require formal operation cognitive level. Besides, a feature of the block-based programming languages is moving programming context from math to programming games, storytelling, and so on. By moving programming context, students can explore the use of different programming constructs by, for example, programming games. By exploring, students have more information to understand the given problem which can result in various forms of cognitive scaffolding: from coding to feedback from playing the game. This process fits into cognitive disequilibrium. Programming settings such as programming language, context, and task (examples) should emerge an optimal level of students’ frustration to motivate students. Programming settings should be challenging enough to provoke an optimal level of frustration. Too hard programming settings can lead to further frustration and students’ overload, while too easy settings can lead to boredom.

Moreover, when programming in block-based programming languages, any programming concept can easily be introduced through programming games and so introducing students to all basic programming concepts during the first lectures. These programming language settings: game programming (or animations, storytelling, and such) using block-based programming language are enabling discovery learning (Bruner 1961). Problem-solving situations trigger discovery learning when the learner relies on his own experience and prior knowledge to solve the problem by interacting with the environment, exploring, and by manipulating objects. When programming games, a student needs to decompose the game scenario into the algorithm form to program it. Moreover, a student must manage the instructions, in the form of puzzles, to construct the program. In the case of the invalid program execution, the student needs to examine the program to find the errors. Through this process, students are using programming constructs without explicitly being aware of it. The teachers’ role is to reveal used underlying programming concepts to the students.

Programming Language Settings

Based on the program input, output, and programming context, programming languages can be introduced to the students in three basic approaches: visual block-based, visual text-based, and procedural text-based.

Table 1 presents a proposal of the appropriate programming language settings based on the cognitive level of the students.

If the learning content surpasses the cognitive level of the student, the student could reach the cognitive overload which can lead to low self-esteem, reducing motivation and success. Therefore, when choosing the appropriate programming language settings for K-12 novices, the teacher must take into account their age. It is beneficial for students to study the programming language that best fits their cognitive characteristics. By choosing the appropriate programming language settings, the teacher could boost the programming concepts learning, which could result in minimizing misconceptions, higher motivation, and satisfaction of the students.

Programming Misconceptions at the K-12 Level,
Table 1 Programming languages and cognitive development

Programming language settings	Piaget's cognitive development levels		
	Concrete	Pre-formal	Formal
Visual -> block-based (such as Scratch, Alice, hour of code)	Optimal	Not challenging	Not challenging
Visual -> text-based (such as LOGO, Python-using turtle library, Greenfoot)	Overload	Optimal	Not challenging
Procedural – > text-based (such as Python, BASIC)	Overload	Overload	Optimal

Otherwise, by introducing an inappropriate programming language, we could lose students for programming. For example, if the teacher presents a text-based procedural language too early for students’ age, most children could, due to the high frustration level, burnout and give up on programming. On the opposite, if the teacher uses block-based language at the level that children already outgrow, frustration level could be too low resulting in boredom and again possible giving up on programming.

Preconceptions, Misconceptions and Programming Languages

Students, considered programming novices, cannot be observed as “tabula rasa.” They have some preconceptions based on previous knowledge which can influence the learning process (Bruner 1977). Preconceptions can be perceived as naïve knowledge which can be easily corrected or removed, while misconceptions are considered as robust to change (Chi and Roscoe 2002). Students can assimilate utterly new knowledge, which is a

more straightforward process than the accommodation when new knowledge is not in accordon to existing schemas (Piaget 1952; Lister 2016).

However, preconceptions based on previous knowledge could lead to misconceptions in new learning context (White 2001). In this case, existing knowledge can interfere with the new one. This process fits into the accommodation process. Therefore, it is imperative to uncover students’ preconceptions to prevent potential misconceptions (Hyslop-Margison and Strobel 2007) for every individual student.

Accommodation is a process where new knowledge must accommodate existing models which do not fit in and can conflict with it. Accommodation can lead to cognitive disequilibrium. That happens when a student is holding two contradictory beliefs. For example, an expression $a = a + 1$ conflicts with the math preconception, where the mentioned expression represents the unsolvable math equation, while in programming, said expression presents assigning a variable value. To solve this cognitive conflict, students must adjust the mental model to accept new information. In the previous example, a student should modify mental model (math preconception) and accommodate additional information about variable value assignment. That is possible through examples of using the mentioned expression, through various examples of variable assignments including the use of different teaching methods, programming languages, analogies, and so on.

There is no doubt that K-12 programming novices have fewer preconceptions than undergraduate novices. By introducing students to programming as early as possible, we can prevent developing at least some misconceptions by helping them to accommodate new knowledge.

Misconceptions in programming refer to incorrect models of some programming concepts. Basic programming concepts are: sequencing, variables, branching, and repeating. Many studies on misconceptions are related to object-oriented concepts which are not appropriate for K-12 students. When it comes to teaching methods, it is essential to thoroughly adopt the basic concepts before moving on with new once. Mastering basic facts and then practicing more complicated ones is an excellent

way to turn a novice into an expert. Therefore, K-12 novices should master mentioned basic programming concepts shifting the teaching focus on the misconceptions of those concepts.

Some misconceptions are based on the syntax of the programming language. By using block-based programming languages, these misconceptions are minimized allowing students to focus on the learning programming concepts instead of struggling with syntax. Children under 12 are more likely to hold misconception than older children. When it comes to previous programming knowledge for children under 17, it is found that knowing Scratch as the previous language decrease tendency to holding misconception, while knowing other language increase it (Swidan et al. 2018). Furthermore, by programming in Scratch, as a block-based programming language, K-12 and high-school students can better understand some programming concepts, such as loop, compared to the text-based programming language (Weintrop and Wilensky 2015; Mladenović et al. 2016b; Li and Hoch 1974), and minimize misconceptions about loops (Mladenović et al. 2018). Though, when learning loops in block-based programming language, students mostly donot have to deal with variables. Moreover, it is noticed that when introducing to variables in Scratch to children between 7 and 17 years of age, it led to errors and difficulties. So, it is not surprising that there is a low percentage of using variables in Scratch projects (Swidan et al. 2018). When programming in Scratch, conditionals, and loops are used up to five times more frequently compared to logic and variables (Maloney et al. 2008).

Block-based programming languages could be an excellent entry to programming for novices, especially at the K-12 level, to meet the programming concepts, but at some point, they should transfer to the “real” text-based programming languages. Therefore, block-based programming languages could be an excellent tool for mediated transfer (Dann et al. 2012) to text-based programming languages. Variables are one of the basic programming concepts and the prerequisite for moving towards the more complex ones. As students mostly donot have to deal with variables when programming using block-based

programming languages, they end up with an incomplete understanding of expressions and operators (Grover and Basu 2017).

Misconceptions About Loops

Repeating or loop concept is one of the fundamental concepts in programming, which is known as a difficult concept for novices. Most programming curriculums, based on the “traditional” text-based programming languages are introducing programming concepts as follows: sequencing, conditionals, and repeating. On the other hand, in block-based programming languages and text-based programming languages with the visual output, such as Logo or Python using turtle library, the usual order of introducing the programming concepts is: sequencing, repeating, and conditionals. Although they share the same underlying idea, loop concept has a different kind of use in text-based and block-based programming languages. Prerequisite concepts for introducing the loop in the text-based programming language by the procedural approach are variables and sequencing. Although conditionals are not necessary, students should be familiar with this concept too to understand the termination of the loop execution. Sequencing is the only pre-required concept for introducing the loop in the programming languages with the visual outcome such as Scratch.

There are two kinds of loops: loops without conditional execution (such as *forever* in Scratch; *for* in Python and Logo) and loops with conditional execution (such as *repeat-until* in Scratch; *while* in Python). Table 2 shows the examples of the fixed bounded loops in Scratch, Logo, and Python. The outcome of all code examples is moving the *Sprite* (Scratch) or *Turtle* (Logo, Python) for ten steps.

Due to the simplicity of the repeat instruction, it is evident that the loop concept can be intuitively introduced in Scratch, while that is far more complicated in Python, especially for K-12 novices.

Loop concept is known as a difficult concept for a long time. Recent studies showed that students, who were programming using block-based

Programming Misconceptions at the K-12 Level, Table 2 Fixed bounded loops

Scratch	Logo	Python
	repeat 10 [fd 10]	<pre>for i in range (10): fd (10)</pre>

programming language, achieved significantly higher scores for the loop concept than students who were programming using a text-based programming language in high schools (Li and Hoch 1974) and elementary schools (Mladenović et al. 2016b, 2018). Moreover, it is noticed that when programming in Scratch, the least common misconceptions were related to loops and conditions (Swidan et al. 2018). Difficulties in loop understanding for text-based programming languages are syntax errors, misunderstanding of the scope of the loop, which lines should be repeated, how many times the code inside the loop will be executed, and so on.

A recent study, conducted in the K-12 school setting tested variable, loop, conditional, Boolean concepts in Scratch. These students previously completed introductory programming course using Scratch. They faced some misconceptions related to loops. In the case of a simple loop with multiple actions, researchers noticed that some students, instead to repeat entire sequence were repeating each action separately. This misconception is called the grouping actions in the loop. It is important to note that in this research, teachers did not spend time describing the changes of variables within the loop (Grover and Basu 2017).

Examples of Detecting Loop Misconceptions in Different Programming Settings

To detect misconceptions about loops at the K-12 level in several programming languages assessments should be carefully designed. As K-12 students are evaluated, the test should not be too complex or too long. To properly compare results, the tasks should be equivalent in all programming languages used. Multiple choice questions are appropriate, but incorrect answers should be designed to reveal some misconceptions. Table 3

shows examples of task and answers for detecting some misconceptions about sequencing and loop concepts in Scratch as block-based and Logo and Python, as text-based programming languages (Mladenović et al. 2018). The question is the same for all questions: How many steps will be made after the execution of the next code?

By analyzing students’ answers, some misconceptions can be revealed. Common students’ mistakes (misconceptions) are grouped into three groups. Table 4 shows detected misconceptions based on the questions showed in Table 3.

By analyzing results, it is found that students using Scratch achieved better results and had significantly fewer misconceptions about loops and sequencing for all tasks than students using Python or Logo. Significantly better results achieved in Scratch could be addressed to the visual representation of the instructions where is a clear difference between a loop and moving instructions in color and shape. Students had similar difficulties in Python and Logo programming languages. Only significant differences between scores in these two programming languages occurred in nested loops task (Q4). The mistake is more frequent in the Python group. Those students mostly had chosen the same wrong answer which refers to interpreting nested loops as two independent loops. As results achieved by Python students did not differ significantly compared to the results achieved by Logo students in the case of simple loops and two loops, this misconception can be addressed to Python syntax where all instructions within the loop are intended under the *for* instruction. This is not a problem for students in single loops, but when it comes to nested loop, the instructions under the inner loop are double indented which is confusing the students.

The programming language can influence the occurrence of the loops’ misconceptions. When

Programming Misconceptions at the K-12 Level, Table 3 Example of codes and answers in Scratch, Logo, and Python

Questions	Scratch	Logo	Python	Answers
Q1		<pre>fd 100 lt 90 fd 50 fd 50 lt 90</pre>	<pre>fd (100) lt (90) fd (50) fd (50) lt (90)</pre>	(a) 100 (b) 150 (c) 180 (d) 200 (e) 380
Q2		<pre>fd 10 repeat 10 [fd 10]</pre>	<pre>fd(10) for i in range (10): fd(10)</pre>	(a) 10 (b) 20 (c) 30 (d) 100 (e) 110
Q3		<pre>repeat 10 [fd 10 rt 10 fd 10]</pre>	<pre>for i in range (10): fd(10) rt(10) fd(10)</pre>	(a) 20 (b) 30 (c) 40 (d) 200 (e) 300
Q4		<pre>repeat 10 [fd 1 repeat 10 [fd 1]]</pre>	<pre>for i in range (10): fd(1) for i in range (10): fd(1)</pre>	(a) 10 (b) 20 (c) 100 (d) 110 (e) 1000
Q5		<pre>fd (1) repeat 10 [fd 1] repeat 10 [fd 1]</pre>	<pre>fd(1) for i in range (10): fd(1) for i in range (10): fd(1)</pre>	(a) 20 (b) 21 (c) 23 (d) 110 (e) 103

using Scratch, as the block-based programming language, K-12 students loops misconceptions are minimized, compared to using text-based programming languages like Python or Logo. As fifth and sixth-grade students are mostly still in the preformal phase of cognitive development, block-based programming languages, such as Scratch, offer them a concrete experience when learning hard programming concepts, in this case – the loop concept.

Misconceptions About Variables

Variables are maybe the critical concept that students should master when learning to program in text-based programming languages like Python or Logo. Understanding of variables is a prerequisite

for moving towards an accurate mastering of the basic algorithms like sequencing, branching (conditional execution of the program), and repeating. Therefore, students have difficulties with writing programs when they did not understand the functions of variables (Shi et al. 2018). Research reported that undergraduate novices while learning conditionals did not understand the purpose and ways to use the variables (Kwon 2017).

There is a lack of researches on this topic at the K-12 level. There are a lot of new block-based programming languages, like Scratch, minimizing the syntax problems while shifting the focus to problem-solving at the same time (Resnick et al. 2009). Besides, K-12 students have fewer misconceptions concerning loops using Scratch compared to text-based

Programming Misconceptions at the K-12 Level, Table 4 Students mistakes in scratch, logo, and python

Mistakes	Questions and answers	Scratch %	Logo %	Python %	Average %
Sequencing concept					
1. Adding the numbers within all instructions	Q1 (e) Q3 (e) Q5 (c)	6.53	25.87	23.37	20.77
Python example: fd (100) lt (90) fd (50)					
Students believe that the turtle will move for 240steps					
Loop concept					
2. Ignoring the instructions outside the loop	Q2 (d)	4.3	21.4	17.5	16.7
Python example: fd(10) for i in range (10): fd(10)					
Students believe that the turtle will move for 100 steps (10 × 10) ignoring the first fd instruction					
Loop concept					
3. Ignoring the nested loop	Q4 (b)	21.7	39.8	65.1	43.5
Python example: for i in range (10) : fd(1) for i in range (10) : fd(1)					
Students are interpreting two nested loops as two independent loops (20)					

programming languages Python and Logo (Mladenović et al. 2018). Hence, students mostly do not have to deal with variables when programming using block-based programming languages; therefore, they end up with an incomplete understanding of expressions and operators (Grover and Basu 2017). Therefore, it is not surprising that variables misconceptions are one of the top three misconceptions among K-12 level students using Scratch, while misconceptions related to control statements: loops and conditions are the least common (Swidan et al. 2018).

Although block-based programming languages are probably more appropriate for the K-12 level, due to syntax problem minimization feature, it is essential to transfer the programming process to the text-based programming languages at some point, which requires a focus on the variable concept.

Most researchers examined misconceptions among undergraduate students. We list the most common variable misconceptions into two groups:

Assigning the values: This group involves several known misconceptions about variables. For assignments such as $a = b$, the common mistake is the reversal assignment of the values (Du Boulay 1986; Putnam et al. 1986). For assignments such as $a = 100 + 1$, some students believe that variable a is holding unevaluated expression rather than evaluated value (Kohn 2017). Further, more the confusing example for students, such as $a = a + 1$ for this is unsolvable math equation, and as such, for many novices, it makes no sense (Bayman and Mayer 1983; Kohn 2017; Du Boulay 1986; Putnam et al. 1986). This misconception may arise from students math preconceptions (White 2001; Sorva 2018; Plass 2015).

Reassigning the value: Some students believe that variables can hold more than one value (Kohn

2017). For reassignments such: $a = 1$; $a = 2$; some students are repeatedly using the initial value instead of the last assigned value (Putnam et al. 1986), while some students believe that reassigned value adds to the initial value (Du Boulay 1986). Mentioned misconceptions are found in text-based programming languages, but they are also noticed in the Scratch programming language among school children (Swidan et al. 2018).

Examples of Detecting Variable Misconceptions in Different Programming Languages

To detect misconceptions about variables at the K-12 level, assessments should be carefully designed. As K-12 students are evaluated, the

test should not be too complex or too long. Multiple choice questions are appropriate, but incorrect answers should be designed to reveal some misconceptions. Table 5 shows examples of task and answers for detecting some misconceptions about variables in Logo and Python programming languages.

To determine misconceptions about variables, answers could be compared in both programming languages. Common students' mistakes (misconceptions) are grouped into five groups (Žanko et al. 2018). Table 6 shows those groups of misconceptions based on the tasks showed in Table 5.

Misconceptions related to assigning the variable values are 1 and 4 in Table 6. Assigning the

Programming Misconceptions at the K-12 Level, Table 5 Tasks and answers

Task	Python	Logo	Answers		
T1	a= 100 a = 20 print(a)	make a 100 make "a 20 pr :a	(a) 20 (b) 100 (c) a (d) 120		
T2	a =100 a = 20 print(' a ')	make "a 100 make "a 20 pr "a	(a) 20 (b) 100 (c) a (d) 120		
T3	a = 100 a = a +1 print(a)	make "a 100 make "a :a+1 pr :a	(a) 100 (b) a (c) a +1 (d) 101		
T4	a = 100 b = a print(a, b)	make "a 100 make "b :a (pr :a :b)	(a) 100 (b) 100 (c) a (d) a	b 100 b 100	
T5	a = 100 b = 20 a = 20 print(a, b)	make "a 100 make "b 20 make "a 20 (pr :a :b)	(a) 100 (b) 20 (c) a (d) 100	20 20 b 100	
T6	a= 100 b = 20 a= 5 print(a, b, b)	make "a 100 make "b 20 make "a 5 (pr :a :b :b)	(a) 100 (b) 100 (c) a (d) 5	20 20 b 20	20 5 b 20
T7	a= 100 b = 20 b = 5 print(a, b, b)	make "a 100 make "b 20 make "b 5 (pr :a :b :b)	(a) 100 (b) a (c) 100 (d) 100	20 b 5 20	5 b 5 20
T8	a = 100 b = 20 a = b b = a+1 print(b)	make "a 100 make "b 20 make "a :b make "b :a+1 pr :b	(a) 21 (b) a+1 (c) 20 (d) b		

Programming Misconceptions at the K-12 Level, Table 6 Common student mistakes probably related to misconceptions about variables

Mistakes	Tasks and answers	Logo %	Python %	Average %
1. Assigning the expression instead of the calculated value	T3 (c)	23.15	46.6	36.6
Python example:	T8 (b)			
<code>a = a+1</code>				
<i>Students believe that the variable holds the entire unevaluated expression as a string</i>				
2. Holding multiple values at a time	T6 (b)	31.5	34.9	33.5
Python example:	T7 (a)			
<code>a = 100</code> <code>b = 20</code> <code>b = 5</code>				
<i>Students believe that the variable b will contain the all assigned values (20 and 5)</i>				
3. When reassigning the variable value, assigning the sum value to the variable	T1 (d)	28.7	21.2	24.4
Python example:	T2 (d)			
<code>a = 100</code> <code>a = 20</code>				
<i>Students believe that the value assigned to the variable a will be the sum of every previously assigned value (120)</i>				
4. Using the symbolic name of the variable instead of its value	T1 (c)	20.38	17.78	18.88
Python example:	T4 (c)			
<code>a=100</code>	T5 (c)			
<code>print (a)</code>	T6 (c)			
<i>Students believe that the variable name rather than its value will print out</i>	T7 (b)			
	T8 (d)			
5. Using the first assigned variable value	T1 (b)	8.9	16.98	13.54
Python example:	T5 (a)			
<code>a = 100</code>	T6 (a)			
<code>a = 20</code>	T7 (d)			
<i>Students believe that the variable a will contain the first assigned value (100)</i>	T8 (c)			

expression instead of a calculated value is the most represented misconception. Misconceptions related to reassigning the variable values are 2, 3, and 5 in Table 6.

Assigning the expression instead of the calculated value was the most frequent misconception which was more highlighted in the Python than Logo programming language. These mistakes refer to the idea that the variable value is a string rather than its previous incremented value which is more highlighted in the Python group than in the Logo group. The mentioned mistake is the most frequent among detected misconceptions and the only one with statistically significant differences between programming languages

between detected mistakes. This finding could be addressed to the several facts:

- The misconception about equality sign is well-known programming misconception. Python expression $a = a + 1$ can be confusing and in a collision with the math preconceptions for programming novices, because such expression can be observed as the incorrect math equation. While trying to find alternative explanations for such expressions, students believe that variable holds an unevaluated expression ($a + 1$) as a string;
- Since the variables are not prerequisite for introducing sequencing and repeating

```
a='Hello world'
print (a)
```

Programming Misconceptions at the K-12 Level,
Fig. 1 An example of Python program

concepts, they are not the main concept in the Logo approach. Opposite, in the procedural-Python approach, variables are the main concept as it is prerequisite for introducing the sequencing, branching (conditionals), and repeating. Consequently, in the Logo approach the variable concept is separate, independent teaching topic with more attention to the concept itself, unlike than simply introducing in procedural approach as the necessary concept for more complex concepts like sequencing, branching, and repeating; Besides, the most common way to introduce the variable concept in the procedural approach is by assigning a string value, as Fig. 1 shows, which is not the case in Logo.

- Incrementing variable value is using in the sixth grade in the procedural approach when for loop is the teaching topic as part of the repeat concept.

Based on the findings revealed in the research, we can confirm that K-12 students may develop misconceptions about variables when using text-based programming languages. When teaching programming at the early stage, teachers should pay more attention to the variable concept taught by the procedural approach with the emphasis on the meaning of the equality sign in the programming and data types in order to minimize the appearance of misconceptions. Besides, more diverse examples of using variables should be used.

Conclusion and Implications for Teaching

Misconceptions of programming concepts are known for more than 30 years. Revealed misconceptions seem to be time resistant. By being

aware of the misconceptions that students can develop, teachers can have a positive impact on minimizing them by using different approaches such as using different programming languages appropriate for target age, changing programming context, using various task examples, and so on.

Most studies about programming misconceptions are conducted at the undergraduate or graduate level. There is a lack of such researches at the K-12 level. Although considered as programming novices, students are not “tabula rasa.” They have some preconceptions based on the previous knowledge. Preconceptions can lead to misconceptions if existing knowledge interferes with the new one. As K-12 students have fewer preconceptions, by introducing them to programming as early as possible, we can prevent developing at least some misconceptions by helping them to accommodate new knowledge.

Block-based programming languages could be the “soft entry” to programming, especially at the K-12 level. As block-based programming languages are syntax-error free, students and teachers can focus on learning programming concepts, such as sequencing, repeating, and branching, respectively. Although the use of the block-based programming languages can boost students’ understanding of the underlying abstract concepts of programming, students mostly donot have to deal with variables when programming in block-based programming languages. Therefore, students should, at some point, move to the “real” programming and transfer learned programming concepts to the text-programming languages. As variables are one of the main programming concepts in text-based programming, it is appropriate to start with it when introducing students to text-based programming languages.

In the end, it is up to the teacher to be aware of the programming misconceptions related to the programming environment chosen. By choosing proper examples, the teacher can create a situation in which students will be able to prevent or minimize the occurrence of programming misconceptions. No single programming language or tool can avoid programming misconceptions occurrence but choosing the appropriate one can lead

to better understanding of the teaching process that can cope with that problem.

Introduction

In public discussions about the value of using modern technologies for teaching and learning, educational researchers and practitioners are expected to take steps beyond acknowledging fashionable trends emanating from the latest release of cutting-edge tools and applications. The real challenge is to explore more systematically and in-depth what really works in education for advancing students’ learning and to effectively link ever-advancing technological functionalities to educational theory and practice. Well-established pedagogical frameworks may or may not guide the effective use of various new educational technologies, and pioneering technological features may or may not make a difference in supporting deep and meaningful learning. Research in education intends to sort out these “mays” from the “may nots” in a serious effort to explain when and why seemingly promising

technologies lead to successful educational practices while others do not. This is the true challenge for primary researchers and the ultimate test for meta-analysts. The entire sequence of related meta-analytical studies addressing various aspects of effectiveness of educational technology is the content of this entry.

Why Meta-analysis

A meta-analysis (M-A) is a systematic synthesis of quantitative results from a collection of primary empirical studies focused on a given research question (or a set of closely related questions, typically of some applied value). A M-A achieves its goals by systematically collecting, sorting, extracting, coding, and analyzing data from the entire corpus of research literature in a certain focal area and, as such, follows a specific set of interrelated procedures (Cooper 2017). For a more detailed overview of the M-A methodology and practice (► [Methodological Quality of Educational Technology Meta-analyses](#)).

What sets an M-A apart from all other forms of literature reviews is that it combines the systematic nature of data collection and analysis with special statistical procedures for aggregating quantitative data (in the form of independent effect sizes) across a multitude of related primary research. This systematic data integration results in creation of an estimate of the central tendency, that is, a weighted average effect size, which is relatively independent from the respective sample sizes, compatible across collected studies, and reflects the overall effectiveness of an instructional intervention in question, thus informing educational practitioners of what to expect and what to prepare for in implementing it. In other words, as of now, M-A is regarded by some researchers as the most informative and, when implemented appropriately, the most reliable source of information for researchers and practitioners.

This entry provides a summary of findings from a series of related meta-analytical studies in the area of educational technology, namely,

- **Second-order M-A** of technology integration since 1984–2009 across subject areas and educational levels (Tamim et al. 2011).

- **Large-scale primary M-A** of classroom technology integration studies in post-secondary education (Schmid et al. 2014).
- **Follow-up M-As** that focus on subcollections from Schmid et al. (2014) addressing:
 - Blended learning (Bernard et al. 2014).
 - Designed interaction treatments (Borokhovski et al. 2012).
 - Pedagogical underpinnings of technology use in teacher education (Tamim et al. 2014).
- **Systematic review and M-A** of tablet use in educational practices – with or without a pedagogical framework – and their effect on learning outcomes (Tamim et al. [under review](#))

This entry provides a comprehensive overview of the array of important conceptual and applied issues that arise with respect to effectiveness (strengths and weaknesses, major purposes, etc.) of technology use to support various aspects of educational process. It offers some reflection on the progression of studies of educational technology – presented both as a summary of their results (derived from strong research efforts), and also as examination of how research questions have been evolving with the focus on different frameworks, types of technology, and conditions of its application for teaching and learning. The entry also discusses what can and cannot be explored by means of different types of M-As and where the most essential findings converge to inform educational practice.

The Evolving Role of Educational Technology

The reliance on computers in various aspects of daily life is a reality for many, and for them, its impact on nearly everything that is done, both personally and professionally, is significant. Why then are educational researchers still engaging in debate over its effectiveness for teaching and learning? Some, like Clark (1983), have insisted on a rather auxiliary role for educational technology (i.e., its functions are not unique, but can be equally effectively substituted by more conventional means of instruction), while others (e.g., Kozma 1991) have argued that its role in education is more substantive and

transformative. The disagreement is probably rooted in the history of educational technology itself.

Originally, technology was utilized almost exclusively to deliver instructional content, and as a medium it was no more effective than a human teacher, even not an especially experienced one. For instance, early studies on distributed closed-circuit television versus live teaching (Carpenter and Greenhill 1955) found no differences between live teachers and televised teachers. Even the development of much more sophisticated computer tools and applications (e.g., computer-assisted learning, multimedia, hypermedia) did not improve student learning outcomes enough for the issue to be considered and resolved unequivocally in favor of educational technology (e.g., Sitzmann et al. 2006).

It was the arrival of what Jonassen (1995) refers to as computer-based cognitive tools that appears to have tipped the scales from what can be achieved using multiple alternative media (i.e., Clark's argument) to what can be achieved primarily through computing (i.e., Kozma's argument). Computer-based communication, simulations, serious games, blogs and wikis, social networking, search and retrieval, and the like, promise unique benefits that go well beyond the simple transfer of content from the teacher to the student. Add to this productivity software like spreadsheets, statistical packages, concept mapping programs, and a host of other student-oriented applications, and we can see that Clark's arguments, while still valid in certain computing domains, must be considered insufficient for examining the overall benefits (and potential deficits) of the introduction and the continued use of computing in education. But even before turning attention to these more refined research question, it might have been expected that some meaningful closure should have been brought to the field with respect to several decades of primary research that tried to determine the overall effect on student learning achievements of educational technology in comparison with instructional practices that did not utilize any technological tools.

Second-Order Meta-analysis – Tamim et al. (2011)

By the first decade of the twenty-first century the amount not only of primary empirical studies but of various types of systematic reviews (including many M-As) accumulated in the field of educational technology, all focusing on nearly an identical research question: how much is using technological tools and applications more or less effective than not using it in classrooms (noting that technology use for the purposes of distance education is beyond the scope of this entry and all M-As that are revisited here). Navigating this vastness has become a real challenge that required some innovative and yet reliable approach to summarize important findings. Responding to this need, Tamim et al. (2011) undertook a second order M-A (i.e., an M-A of M-As) entitled “What forty years of research says about the impact of technology on learning.”

The second-order M-A approach offers the potential to summarize a growing body of meta-analyses, over a number of years, in the same way that a meta-analysis attempts to reach more reliable and generalizable inferences than individual primary studies (e.g., Peterson 2001). In this second-order M-A, 25 previously published M-As that cut across all levels of formal education, subject areas and technology types, from the 1970s to the present, were selected from a pool of about 75 M-As (by the criterion of the lowest possible overlap among primary empirical studies) and their results were synthesized. The random effects model analysis revealed a weighted average effect size of $\bar{g} = 0.35$ ($p < 0.01$), encompassing 1,055 primary studies and 109,700 participants. Moreover, this result was further validated through identifying and reanalyzing independent studies from these M-As that reported references to their respective “includes” (there were 574 independent effect sizes with the total number of students being 60,853) in the standard meta-analytical procedure. Remarkably, the overall weighted average effect size of this validation study (also according to the random effects model) was nearly identical to the

Promises and Prospects of Educational Technology, Evidence from Systematic Reviews and Meta-analyses, Table 1 Mixed-effects moderator variable analysis of methodological quality of reviewed M-As

Methodological Quality Category	<i>K</i>	$\bar{g}$	<i>SE</i>	<i>CI</i> : Lower 95th	<i>CI</i> : Upper 95th
Low	8	0.42*	0.07	0.28	0.56
Moderate	7	0.35*	0.04	0.27	0.43
High	10	0.31*	0.03	0.25	0.37
Test of category differences		$Q_{\text{Between}} = 2.68$ ($df = 2$), $p = 0.29$			

* $p < 0.05$

one revealed in the second-order M-A: $\bar{g} = 0.33$ ($p < 0.01$), providing extra credibility for it.

In addition, two moderator variable analyses (mixed model) produced statistically significant outcomes. Technology use in K-12 formal educational settings (i.e., from kindergarten to final school grade before entering the post-secondary education for learners ranging in age roughly from five-six to seventeen-eighteen years) seemed to have higher effect on learning ($\bar{g} = 0.40$, $k = 9$) than it did in post-secondary education ($\bar{g} = 0.29$, $k = 11$): $Q_{\text{Between}} = 4.83$ ($p < 0.05$), and technology use in a general category “for instructional support” was more effective ($\bar{g} = 0.42$, $k = 10$) than it was in “for direct instruction” (i.e., content delivery) category ($\bar{g} = 0.31$, $k = 15$): $Q_{\text{Between}} = 3.86$ ($p < 0.05$). The latter result is of particular interest as it is capable of further informing practice (i.e., what kinds of pedagogical use of technology and various potential blends thereof are more promising), while opening the whole line of research on major purposes (i.e., key applied functions) of educational technology use that have produced some consistent findings, presented and discussed in more detail later in this entry.

There was another important outcome which, though it did not reach the level of statistical significance, clearly demonstrated a linear tendency for M-As of lower methodological quality (e.g., those that included studies of preexperimental research design or were implemented with some noticeable deviation from the best meta-analytical practices as outlined, for instance, in Cooper 2017 or Tamim et al. under review) to produce larger effect sizes, whereas effects of more rigorously implemented ones tended to be more modest in magnitude

(Table 1), the issue picked up in a related entry of this volume.

Thus, Tamim et al. (2011) addressed the question based on M-As that looked at the *technology* versus *no technology* question. The authors concluded that, generally speaking, educational technology does enhance learning, even if only to a relatively small extent.

However, this second-order M-A could not be considered the final word on the topic of technology integration in education for two major reasons. A second-order M-A, in general, as pointed out by Cooper and Koenka (2012), represents a limited means for addressing the host of peripheral questions, those that only can be settled in a primary M-A, where coding decisions are made by the meta-analyst based on detailed descriptions of various study characteristics supposedly provided by the authors of primary research, and the synthesis is conducted at the more granular level of the individual effect sizes. As a result, Tamim et al. (2011) could not examine a number of substantive and demographic moderator variables and thus provided insufficient texture or nuance to the overall results.

Another challenge that could not be fully met by this second-order M-A is rapidly changing educational landscape that tends to include more new technological tools and applications introduced to instructional practices in different amounts, combinations and under varying circumstances so that the classical comparison type of “technology versus no technology” (covered by so many M-As summarized in Tamim et al. 2011) is no longer the predominant classroom reality. Relatively recently, but gradually more and more prevalent, “technology versus technology” (more versus less or/and different kinds of)

type of educational settings (and subsequently type of comparison in empirical research) has become a more reasonable and more pressing question in modern education. The need to address and overcome (at least, partly) both these issues hence motivated the effort by Schmid et al. (2014) to perform a large-scale primary M-A of technology integration in postsecondary education.

Large-Scale M-A for a More Nuanced Understanding – Schmid et al. (2014)

While primary sample-based research is intended to provide an inferential link between a sample under scrutiny and the population that it is presumed to represent, M-A makes this link more explicit by examining the effects of a multitude of primary studies that have attempted to address the same question. Inferential statistics and associated assessment of significance are unnecessary because a M-A investigates the entire population of primary studies with like characteristics and conducted within a specified timeframe. In this sense, M-A looks at the “big picture,” or the characteristics of the phenomenon in terms of the entire body of primary studies that have examined it (including inspection of their specific characteristics – that is, study features, potential consistent influence of which on the magnitude of the effect size are assessed through moderator variable analysis).

The Schmid et al. (2014) M-A reported the overall weighted average effects of technology use on achievement and attitude outcomes and explored a fairly large set of moderator variables. Educational technology was broadly understood in terms of the earlier definition by Ross et al. (2010) as a “. . . variety of modalities, tools, and strategies for learning, [whose] effectiveness, therefore, depends on how well [they] help teachers and students achieve the desired instructional goals” (p. 19). Recognizing the limitations of the *technology versus no technology hypothesis* (i.e., comparisons between technology-enhanced and technology-free classrooms), Schmid et al. (2014) divided the entire collection of included studies into those with no technology in the

control condition and those with technology in the treatment condition and some technology in the control condition. To facilitate navigation through the review, here is a brief summary of major terms and definitions used in the M-A, followed by a set of inclusion/exclusion criteria and the key aspects of the review methodology (for the complete description of the methodology, please see Schmid et al. 2014).

Terms and Definitions

Educational technology is understood here according to Ross et al. (2010), as quoted previously. The *degree of technology use* was the primary determinant for assigning groups to either the experimental or the control condition. This distinction is important because it specifies the valence (positive/negative) of the effect size. Two types of studies were found, those that (similar to the research question of the second-order meta-analysis presented earlier) contained no technology in the control condition and those that contained some technology in the control condition. In the former class of studies, the assignment of the experimental and control group designation was clear. In the latter case, the differential use of technology in the two conditions was rated. The condition containing the “highest degree of technology use” (or more technology-saturated) was designated the treatment condition and the alternative condition served as its control. There were three possible interpretations of higher degree of technology use. The experimental group was considered: a) to contain the longest or most frequent exposure to technology tools; b) to contain more advanced technology (i.e., enabling more functions); and/or c) to employ a larger number of technology tools.

There were the following major purposes of technology use identified and analyzed in the reviewed studies:

- 1) To promote communication and/or to facilitate the exchange of information. This category includes technology that enables a higher level of interaction between individuals (i.e., two-way communications among learners and between learners and the teacher).

- 2) To provide cognitive support for learners. This category encompasses various technologies that enable, facilitate, and support learning by providing cognitive tools (e.g., concept maps, simulations, wikis, different forms of elaborate feedback, spreadsheets).
- 3) To facilitate information search and retrieval. This type of technology is intended to enable and/or facilitate access to additional information (e.g., web links, search engines, electronic databases).
- 4) To enable or enhance content presentation (e.g., Microsoft PowerPoint presentations, graphical visualizations, computer tutorials with limited interactive features).

When more than one purpose was identified, codes indicating multiple purposes were created (e.g., cognitive support plus presentational support). Achievement outcomes included various objective measures of academic performance (e.g., examination/test scores), but not self-evaluation. A wide spectrum of moderator variables were coded and analyzed: methodological (e.g., research design), instructional (e.g., purpose of technology use, pedagogical approach), demographic (e.g., subject matter), and publication (e.g., date, source).

Inclusion/Exclusion Criteria and Review Procedure

Studies under review that were included had to have the following characteristics: (1) be published no earlier than 1990; (2) be publicly available (or archived); (3) address the impact of computer technology on student achievement and/or attitudes; (4) contain at least one between-group comparison, where one group fits the definition of the experimental condition and the other group fits the definition of the control condition, using the criterion of the degree of technology use (higher versus lower); (5) be conducted in a formal post-secondary educational setting; (6) represent classroom or blended instructional environments, but not distance education; and (7) contain sufficient statistical information for effect size extraction when the latter is methodologically attributable to the effect of technology use and not to the influence of other factors.

Failure to meet any of these criteria led to the exclusion of the study with the reason(s) for rejection documented for further reporting. Two researchers working independently rated the studies, first at the abstract level, then at the full text level, on a scale from 1 (definite exclusion) to 5 (definite inclusion). All disagreements were discussed until they were resolved, inviting a third opinion when necessary, and initial agreement rates were calculated as Cohen's Kappa (κ) and as Pearson's r (where appropriate). Similarly, two researchers participated in all other data extraction procedures (i.e., effect size extraction and study feature coding).

Literature Search Strategies and Data Sources

Extensive literature searches (as outlined in detail in the original publication) were designed to identify and retrieve primary empirical studies relevant to the major research questions. Key terms used in search strategies, with some variations to account for specific retrieval sources, included ("technolog*," "comput*," "web-based instruction," "online," "Internet," "blended learning," "hybrid course*," "simulation," "electronic," "multimedia" OR "PDAs" etc.) AND ("college*," "university," "higher education," "postsecondary," "continuing education," OR "adult learn*") AND ("learn*," "achievement*," "attitude*," "satisfaction," "perception*," OR "motivation," etc.) AND excluding "distance education" or "distance learning" in the subject field.

The following databases were among the sources examined: ERIC (WebSpurs), ABI InformGlobal (ProQuest), Academic Search Premier (EBSCO), CBCA Education (ProQuest), Communication Abstracts (CSA), EdLib, Education Abstracts (WilsonLine), Education: A SAGE Full-text Collection, Francis (CSA), Medline (PubMed), ProQuest Digital Dissertations & Theses, PsycINFO (EBSCO), Australian Policy Online, British Education Index, and Social Science Information Gateway.

In addition, Google Internet searches were performed to help identify gray literature, including a search for conference proceedings. Review entries and previous M-As were used for branching, and the tables of contents of major

journals in the field of educational technology (e.g., *Educational Technology Research & Development*) were manually searched.

Effect Size Calculation and Synthesis

A *d*-type standardized mean difference effect size was used as the common metric (i.e., Cohen’s *d*), and then was transformed into Hedges’s *g* metric (Hedges and Olkin 1985) to provide necessary correction for small sample sizes. The random effects model (Borenstein et al. 2010) was the main analytical approach for this M-A. A mixed effects model was used to test the difference in levels of moderator variables. In a mixed analysis, average effect sizes for categories of the moderator are calculated using a random effects model. The variance component *Q*-Between is calculated across categories using a fixed effect model (Borenstein et al. 2010). All analyses, including sensitivity and publication bias analysis, were performed in *Comprehensive Meta-Analysis*™ 2.2.048 (Borenstein et al. 2008).

Results of Schmid et al. (2014) Meta-analysis
Out of an initial pool of 11,957 study abstracts, 674 primary studies were retained for analysis, yielding 879 independent achievement effect sizes after pre-experimental designs and studies with obvious methodological confounds removed. The overall random-model results of the Schmid et al. (2014) study are shown in Table 2. The produced weighted average effect size of 0.27 was significantly greater than zero. The collection of effects is significantly heterogeneous, based on findings from the fixed model where heterogeneity is tested in terms of the magnitude of *Q*_{Total} (variability). An effect size of

0.27 is considered small and represents a difference of 0.27*sd* between the mean of the treatment condition and the control condition, amounting to about an 11% difference. These results suggest that technology-supported instruction is advantageous compared to either non-use or limited use, but that this advantage is relatively modest.

The collection of achievement outcomes was divided into two subcollections, according to the amount of technology use in the control condition; these were “no technology” in the control condition ($\bar{g} = 0.25, k = 479, p < 0.01$) and “some technology” (though necessarily a lower degree of its use than in the treatment condition) in the control condition ($\bar{g} = 0.31, k = 400, p < 0.01$). Random effects multiple meta-regression analysis was run on each subcollection revealing three significant predictors (subject matter, degree of difference in technology use between the treatment and the control, and pedagogical uses or major function of technology). The set of predictors for each subcollection was both significant and homogeneous. Differences were found among the levels of all three moderators, but particularly among varieties of cognitive support applications. These findings are presented in greater detail later.

In summary, the Schmid et al. M-A was intended to (1) overcome some of the limitations of the previous reviews, including lower level of detailed information about individual primary studies in Tamim et al. (2011); (2) provide the most comprehensive first-order M-A of technology use in post-secondary classroom education; (3) encompass studies with “no technology in the control condition” and studies with “various degrees of technology in each condition”; and (4) look at the pedagogical use of a broad range of educational technologies and other important instructional moderator variables. Based on its major outcomes, several follow-up M-As were designed and implemented.

Promises and Prospects of Educational Technology, Evidence from Systematic Reviews and Meta-analyses, Table 2 Overall weighted average effect size (random effects model)

Population estimates	<i>k</i>	$\bar{g}$	<i>SE</i>	Lower 95th	Upper 95th
Final collection	879	0.27*	0.02	0.24	0.31
^a Heterogeneity analysis	$Q_T = 3,183.10$ ($df = 878$), $p < 0.001$, $I^2 = 72.42$				

* $p < 0.01$

^aBased on the fixed effect model for $k = 879$

Examining the Details: Three Follow-Up Meta-analyses

A set of subsequent M-As addressed several additional questions, judged to be of high importance.

More specifically, the effects of various purposes of technology use (with the focus on cognitive support for learning), technology use in blended learning, instructional settings (interaction treatments) designed specifically to enable student collaborative work, and various pedagogical approaches to teacher education were investigated. Following is a brief rationale for each of these follow-ups.

Major Purpose of Technology Use

As educational technology advanced beyond media whose primary role was to deliver content to students (e.g., instructional television, multimedia applications, computer-assisted instruction), the following question arose in the theoretical and practical literature: “How can computers be used to support student cognition, without directly instructing them?” Jonassen (1995) addresses the practical issue, but Cobb (1997) provides a possible answer to the theoretical question. He argues that the most compelling role of computing in learning is its ability to afford “cognitive efficiencies” to students. In most, if not all, learning situations there is shared cognition among the learner, the task itself, and the tools that the learner uses in the process. Computer-based cognitive tools, he argued, could be designed and implemented to fulfill one of these roles. His rationale was that the more the learners can distribute cognition “outside of their heads,” the more the cognition that can be devoted to the process of learning new material. Therefore, one purpose of the Schmid et al. review was to explore whether and to what extent cognitive tools promote student achievement in learning environments involving technology, compared to other roles that computers might assume (e.g., presentation, search and retrieval, communication).

The Effects of Blended Learning

There is a growing literature of studies investigating blended learning, an instructional approach that involves a combination of elements of face-to-face and online instruction. It is sometimes argued that blended learning is the “best of both worlds” because it is a marriage of the best elements of the two practices, although it is still

arguable what these “best elements” are and how exactly they fit together. To date, there have only been a limited number of M-As devoted to blended learning (e.g., Means et al. 2013; Bernard et al. 2014, reported here; Spanjers et al. 2015).

In the Means et al. (2013) M-A, blended learning conditions were found to significantly outperform fully face-to-face classroom instruction ($\bar{g} = 0.35$, $k = 23$, $p = 0.001$). Several moderator variables were significant: 1) blended learning outperformed self-study; 2) collaborative learning and teacher-directed expository instruction significantly outperformed self-study; 3) in computer-mediated communications with instructor and among students, the asynchronous mode only was more effective than in combination with the synchronous mode; and 4) undergraduate students benefited more from blended learning than graduate students.

In the Spanjers et al. (2015) study, the overall effect size favored blended learning ($\bar{g} = 0.34$, $k = 24$, $p < 0.05$) for achievement based on objective effectiveness outcomes and ($\bar{g} = 0.34$, $k = 11$, $p < 0.05$) for achievement based on subjective effectiveness outcomes. These results closely mirror the Means et al. (2013) results. The presence or absence of quizzes appeared to differentiate the overall result in terms of objective effectiveness.

The Bernard et al. (2014) study, an offshoot of Schmid et al. (2014), addressed the following research questions: What is the impact of blended learning (i.e., courses that combine face-to-face and online learning) on the achievement of higher education students? How do various pedagogical factors (e.g., the amount of time spent online and the purpose of technology use) and course demographics (e.g., subject matter) moderate the overall average effect size? These findings appear in a later section.

Designed Interaction Treatments

Institutions of higher education provide students with the opportunity to interact with each other both inside and outside the classroom. Three major forms of interaction are important for effective learning, extrapolated from the distance education literature (e.g., Anderson 2003; Moore

1989). *Student–student* interaction refers to interaction among individual students or among students working in small groups. *Student–teacher* interaction traditionally focused on, but is not limited to, classroom-based dialogue between students and the instructor. Finally, *student–content* interaction refers to students interacting with the subject matter under study to construct meaning, relating it to personal knowledge, and applying it to problem-solving. Meta-analytical findings support the overall positive influence of the three types of interaction on learning outcomes with specific emphasis on student–student interactions (Bernard et al. 2009). Naturally, all three of these forms can occur in higher education classrooms without technology, but it was the intention of this study to investigate student–student interaction, supported by technology, in conditions that were specifically designed to support collaborative learning. Thus, the research question became, “Are *designed interaction treatments* (i.e., intentionally implemented collaborative instructional conditions that are meant to increase student learning) more effective than *contextual interaction treatments* (i.e., learning setups that contain conditions for student–student interaction to occur, but are not intentionally designed to create collaborative learning environments in technology-enhanced classroom instruction in higher education)?” This question is important because it emphasizes the use of instructional design to facilitate the potentially positive effects of technology use in higher education classrooms Borokhovski et al. 2013) in general, including preservice teacher training.

Technology Use in Teacher Education

Another follow-up of Schmid et al. (2014) focuses on the subset of studies that specifically addressed technology use in educational and teacher training programs. The main objective was to further explore the impact of technology use in this specific context in an attempt to determine what aspects of teaching practices set education apart from STEM (Science, Technology, Engineering, and Mathematics) and non-STEM disciplines. Moreover, it aimed to investigate the nature of the most effective pedagogical frameworks

supporting successful technology integration. The focus was on how technology was used by educational professionals to achieve educational goals.

While it is impossible to review all pedagogical frameworks available to instructors, it seemed appropriate to focus on student-centered instructional strategies. It is argued that the learner-centered approach supports learning by emphasizing the student’s role in the instructional environment, thus shifting the focus from knowledge transmission to the actual learning process (e.g., Laurillard 2002). Regardless of technology integration, general teaching strategies that are aligned with the student-centered philosophy include cooperative and collaborative learning (Bruffee 1993; Johnson and Johnson 2008); problem-based learning (Jonassen et al. 2003); and the provision of elaborate feedback (Hattie and Timperley 2007).

The Follow-Up Meta-analyses

Major Purpose of Technology Use

Study results become differentiated when effect sizes are divided by pedagogical application of technology. The results from Schmid et al. (2014) indicate that technology that is used to support student cognition outperforms all other categories, but especially presentational support (Table 3). This effect is interpreted as a difference primarily between “technology used by students” (for content understanding) and “technology used by teachers” (for content delivery). Other functions, such as support for communication and a mixture of cognitive and presentational support, fall in between these two.

Blended Learning

The effects of blended learning (i.e., partly in class and partly online) were derived from the Schmid et al. (2014) database and analyzed and reported in Bernard et al. (2014). As evident from Table 4, the random-effects weighted average effect size ($\bar{g} = 0.334$, $k = 117$) is larger than the overall average effect of technology use in the original M-A, and is in line with the findings from the other M-As of blended learning (Means et al.

Promises and Prospects of Educational Technology, Evidence from Systematic Reviews and Meta-analyses, Table 3 Instructional moderator variable analysis: Major function of technology use

Levels of Technology Use	<i>k</i>	$\bar{g}$	Lower 95th	Upper 95th	Q_{Between}

2013; Spanjers et al. 2015). Apparently, there is an advantage that accrues from balancing face-to-face instruction with online learning outside of class. The mechanisms of this effect have not been determined, so one of the challenges of educational technology research of the future will be to tease out the effects of variables such as amount of time devoted to each pattern of instruction, the most effective learning strategies, and the teacher’s role in the online portion of blended learning.

Interaction Treatments

Interaction treatments were defined by Bernard et al. (2009) as instructional setups in distance education that are intended to facilitate and promote interaction among students, between students and teachers, and between students and the content. This definition was used to code studies

in the Schmid et al. (2014) study in classroom settings. Table 5 shows the results of this basic analysis. Conditions where interactions were greater in the treatment group, compared to the control condition, produced results that were significantly higher than the rest of the comparisons, especially those in which the control group was characterized as having more potential for interactions among learners. As expected, when the two conditions were roughly the same (i.e., $\bar{g} = 0.29$, $k = 703$), the outcome was not significantly different from the former condition (i.e., $\bar{g} = 0.34$ versus 0.29).

When the interaction treatments are divided further by the presence or absence of design intention, the results strongly support *designed interaction treatments* over *contextual interaction treatments* (Table 6). It appears that merely providing the means for student–student interaction

is not enough as a pedagogical strategy. Some form of instructional design is needed (e.g., collaborative learning, reciprocal teaching).

Technology Use in Education Courses

In this final section, the effects of educational technology across subject areas are investigated. Because of contemporary interest in teacher education (i.e., teaching future teachers), these studies are broken out from other Non-STEM content areas and their average effect size compared with that of STEM (i.e., science, technology, engineering, mathematics) and the remaining Non-STEM subject areas. The results, shown in Table 7, revealed nearly equal average effects for STEM and Non-STEM education, but a noticeable difference between these areas and technology used in teacher education.

To investigate further what might account for such a high average effect for teacher education, studies were further classified according to the underlying pedagogical frameworks for using technology in these studies (Table 8). Only studies from the education sub-group, where there was a clear indication of a particular pedagogical approach to instruction and associated use of technology, were included. This reduces the number of effect sizes from *k* = 66 to *k* = 39. Although this number after the split somewhat limits the power of subsequent analyses, using technology to provide feedback to students resulted in an unusually high average effect size of $\bar{g}$ = 0.75 (*k* = 11). Two other instructional approaches to technology use were also prominent: multimedia theory and problem-based learning were each around $\bar{g}$ = 0.50. Notably, the use of technology

to support collaborative learning (i.e., group projects) was very low (less than $\bar{g} = 0.10$) and not significantly greater than zero. These findings suggest the need for further exploration of the range of technology uses in education, as well as in allied areas such as nursing education.

The subcollection of studies that focused on STEM subject matters was further explored for effects of several moderator variables (Tamim et al. 2015a). This study found no significant differences across categories of STEM subject areas: $Q_{\text{Between}} = 2.80$, $df = 3$, $p = 0.42$, with the highest magnitude of the effect for mathematics ($\bar{g} = 0.35$, $k = 69$) and the lowest for engineering ($\bar{g} = 0.23$, $k = 41$). In other words, the effect of technology use was quite consistent within the STEM domain, which indirectly supports treating these fields of study as a coherent conglomerate of related subject areas, at least in postsecondary education. At the same time, previously described findings in favor of technological tools used for cognitive support for learning received its additional confirmation specifically for STEM education: $Q_{\text{Between}} = 7.06$, $df = 1$, $p = 0.008$.

What Next

The series of M-As presented encompassed various aspects of research in the field of technology integration in education, which was broadly understood as all types of computer-based instructional practices. Lately, the attention of researchers and practitioners is gradually shifting toward identifying and closely examining more specific tools and applications that may present some kind of a break-through and fulfill a longstanding promise of seriously changing educational practices and outcomes. Two particularly prominent patterns could be named. One deals with more and more sophisticated technologies, such as interactive simulations and serious games that target learning and expertise development in specific subject matters, like science, engineering, and health education. Another turns more in the direction of multifunctional mobile devices that are reasonably affordable, so that they could be ubiquitously available to students and used for a multitude of learning goals. Both directions can give rise to related research, including systematic

reviews and M-As. See, for example, research summaries on: simulations in STEM education (e.g., D'Angelo et al. 2013), digital serious games (e.g., Clark et al. 2016; Wouters and van Oostendorp 2013, where the latter emphasized not the games per se, but the value of instructional support in digital gaming environments), and ubiquitous laptop instructional interventions (e.g., Zheng et al. 2016).

The next section presents an overview of a recent systematic review and an M-A of tablet use in educational contexts (e.g., iPad, iPod, PC [personal computer or Android-based] tablets), an overview of large-scale government initiatives of tablet use in education around the globe (Tamim et al. 2015b) followed by a systematic review of research investigating the impact of tablets on students' performance (Tamim et al. 2015c), which was further updated with the focus on comparative quantitative research (Tamim et al. 2017).

Mobile Technology

At the present time, there is an abundance of institutional, regional, and national initiatives that make use of mobile devices in school-based elementary and secondary (i.e., K-12) and higher education contexts. This is evident in the large-scale government-led initiatives to distribute tablet devices to students in K-12 schooling sectors in eleven countries around the world (Tamim et al., 2015). Limited attention has been given to best practices or lessons learned from research, and there is a need to ensure that empirical evidence is synthesized and shared in a timely fashion. A systematic review of research studies published since 2010 and addressing the impact of tablets' use on students' achievement has been completed. In light of the relative recency of tablet introduction into classrooms and the potential shortage of related experimental research, the systematic review covered both quantitative and qualitative research studies. The review included the following:

A-. *Meta-analysis* aiming at synthesizing quantitative research with the objective of

answering two complementary but distinct research questions:

1. What is the impact of tablets on students' achievement when compared with treatments that do not utilize tablets for instructional purposes?
2. What is the impact of tablets when utilized with the support of a pedagogical framework on students' achievement in comparison to their use in an absence of a pedagogical underpinning?

B-. *Qualitative Research Review* with the objective of reviewing qualitative research to gain an understanding of students' perceptions about the most prominent aspects of effective tablet use for teaching and learning.

A focused search strategy was designed with the research being reviewed for inclusion upon meeting the following inclusion criteria:

- Be published in English 2010 onward.
- Feature educational use of tablets (laptops and smartphones excluded).
- Allow for comparison between two instructional conditions with tablets in one or both groups.
- Describe primary empirical research of all designs except for "one group pre-to-post-test" preexperimental design (the latter were considered for possible inclusion in the qualitative research review).
- Be conducted in formal educational settings addressing general student populations.
- Report measures of student achievement and contain sufficient statistical information to enable effect size extraction.

A targeted search strategy was developed to encompass a broad variety of sources including ERIC; Education Full Text (Wilson); Education Source; EdITLib; ProQuest Dissertations & Theses databases, as well as Internet manual searches and branching. After removal of duplicates, a total of more than 2,000 unique records were retrieved at the abstract level. Two independent researchers reviewed approximately 45.5% of the collection and met to resolve disagreements. After

establishing reliability agreement rate of 92.4% (Cohen's $\kappa = 0.85$), the researchers completed the review of the second half of abstracts separately. The same approach was taken for the review of retained 443 full-text documents with the agreement rate of 93.3% (Cohen's $\kappa = 0.87$). Full-text review resulted in a final included set of 118 primary studies that fell into the following categories:

- 69 quantitative research studies used in the meta-analysis that resulted in a total of 86 unique effect sizes.
- 7 quantitative research studies with one group pre-to-post-test design that were used in the qualitative literature review since they were judged to be informative of tablet-based instructional interventions.
- 42 qualitative research studies (case studies, observations, broad-scope surveys, interviews, etc.) were used in the qualitative literature review.

Analysis revealed significant low-to-moderate average effect sizes of tablet use in comparison with no-tablet contexts. However, it was also clear that decisions with respect whether or not to introduced tablets to the instructional practice were made for a variety of reasons – from just following a fashionable trend to the intend to enable carefully designed pedagogical interventions that take into account and rely on functional richness of "smart" mobile technology. The latter usually took form of teaching and learning we called "technology plus" (pedagogy-driven) instructional conditions, where the use of technology is determined by instructional design and/or teachers' understanding of its capacity to fulfill relevant learning objectives. Findings indicated that those pedagogically sound tablet-enhanced instructions resulted in even stronger effect-sizes when compared to what could be described as convenient tablet use. Table 9 shows average weighted effect sizes for student achievement outcomes for both fixed and random models, with associated statistics. Although there is no direct comparison possible between the tablets/no-tablets and the tablets+/tablets, results are in line with

Promises and Prospects of Educational Technology, Evidence from Systematic Reviews and Meta-analyses, Table 9 Overall achievements effects for both research questions

	<i>k</i>	<i>g</i> ⁺	Lower 95th	Upper 95th
<i>Question 1: Tablets vs. no tablets</i>				
Random effects model	65	0.222	0.12	0.32
Fixed effect model	65	0.194	0.15	0.24
Heterogeneity (fixed effect model)	$Q_T = 245.05$	$df = 64$	$p < 0.001$	$I^2 = 73.88$
<i>Question 2: Tablets with enhancements vs. unmodified tablet use</i>				
Random effects model	21	0.784	0.50	0.52
Fixed effect model	21	0.635	1.07	0.75
Heterogeneity (fixed effect model)	$Q_T = 106.36$	$df = 20$	$p < 0.001$	$I^2 = 81.20$

previous research findings (e.g., Schmid et al. 2014) and are suggestive that specifically designed technology-based instructional interventions have higher potential for learning than modern technology per se.

Qualitative Research Synthesis

The qualitative research review included 49 studies with the objective of offering an in-depth understanding of effective use of tablets as perceived by the students. The qualitative studies reflected students’ overall positive perceptions of tablet use in educational contexts, which seem to be stronger within more student-active contexts. The narrow scope of the projects and/or limited information provided in the entries did not allow for critical analysis and reflection. Nevertheless, substantive study features, a brief overview of the treatment, and overall findings for each of the studies were extracted. Some of the more commonly cited advantages by students included the following:

- Improving organizational and note-taking skills.
- Enhancing ability to express themselves and their understanding in creative ways.
- Supporting their independence and communication skills.
- Increasing accessibility to resources while supporting complex visualization of concepts.
- Improving their literacy and mathematics skills.

As for the most commonly cited challenges, they were as follows:

- Technical issues and needed expertise.
- Distracting nature of the device and plethora of Apps.
- Pressing need for teachers’ professional development to enable them to integrate the use of the device for the enhancement of the teaching and learning process.

Discussion

The current entry provides a review of findings from a substantive body of M-As and systematic reviews completed by researchers in the area of educational technology. The main research questions that were addressed include the following:

1. What is the overall weighted average effect size and variability for studies that investigate the impact of the instructional uses of technology on student achievement outcomes?
2. Is there a difference in average effect sizes for achievement outcomes associated with major purposes of technology use?
3. What is the weighted average effect size and variability for studies that investigate the impact of the instructional uses of technology in so-called blended education?
4. Is there a difference in the weighted average effect sizes for achievement outcomes associated with designed versus contextual interaction treatments?
5. What is the effectiveness of instructional technology in teacher training dependent on a particular pedagogical approach/framework?

6. What is the overall effect of using tablet technology in education in comparison with technology-free instructional environments?
7. Is there added value of enhancing tablet-based learning in comparison with the random use of mobile technology in classrooms?

Overall Findings

Both second order all-encompassing M-A (Tamim et al. 2011) and large-scale primary M-A of technology integration in postsecondary education (Schmid et al. 2014) were coherent in the major message they delivered that educational technology does have a positive, though rather modest (low or low-to-moderate) effect on students' learning outcome across subject areas and grade levels. The magnitude of the overall weighted average effect sizes in these two M-As was quite compatible ($\bar{g} = 0.35$ and $\bar{g} = 0.27$ – for the former and the latter, respectively, also parallel to the findings of the validation study: $\bar{g} = 0.33$), both significantly heterogeneous.

Cognitive Versus Presentational Support Tools

Based on the analyses of the purposeful use of technology, we see where Clark's original assertions about the passive nature of technology may have arisen. Technologies prior to the 1980s and well into the 1990s were indeed passive because their primary purpose was to convey content to students, either through the actions of teachers' use of presentational software or as a consequence of computer-aided instruction (CAI). Feedback, of course, was present in these stand-alone technologies, but it often amounted to simply providing the "right answer" without elaboration (Azevedo and Bernard 1995). Not until the advent of personal computers, and especially software and online tools that "work with" the student in the learning process, have changes in technology use that educators could not have envisaged prior to 1980 been seen, when much of Clark's work was done.

The overall message emerging from these data is that learning is best supported when the student learns through meaningful activities via technological tools that provide cognitive support during

the learning process. However, we are a long way from understanding more specifically how to design effective cognitive support tools (which could be of two very distinct broad categories: those enabling distributed cognition – e.g., worksheets, spellcheckers; and those supporting understanding and deep learning – e.g., simulations) and when precisely to integrate them into instructional practices. Research programs to help bridge knowledge gaps in these areas are considered of value.

Blended Learning in Higher Education

For the longest time, there were two primary venues for learning in higher education – classroom instruction (with or without technology support) and distance education, which has evolved into online learning. While there is considerable evidence that technology that is used to support classroom instruction is beneficial, it is a requirement when students and teachers are in separate locations, often working asynchronously (in the correspondence education era, when the post office provided a transfer technology). It is now possible to marry these two environments, providing students with some time in classrooms and the rest – online out of classrooms. The results of studies of these so-called blended or hybrid learning experiences are encouraging (Means et al. 2013; Bernard et al. 2014; Spanjers et al. 2015), but it is still not possible to predict with confidence which variables are most influential (e.g., instructional strategy applied in each context) and which are trivial (e.g., time spent in each pattern), or how to design effective blended learning given the myriad of circumstances that can arise under various conditions. Research work in this domain could well be of value to university students.

Collaborative Interaction Treatments

A M-A has identified the link between the intentioned and designed use of technology in higher education classrooms and the provision of technology without such explicit intention, though generally high heterogeneity of meta-analytical findings indicates that, dependent on a particular educational context, observed effects might grow or diminish and suggests caution in

their overall interpretations. These results provide educators with specific guidance about what works and does not work in the domain of education, especially as it relates to technology-based student–student interaction. This part of the M-A reaffirms the effectiveness of computer-supported collaborative learning (CSCL) from the perspective of technology use and the design of instruction that aims to support and amplify interaction. Once again, pedagogy and specific instructional design take precedence over the contextual communicative benefits of modern educational technology.

Technology Use in Teacher Education

Current analyses have moved one step beyond responding to the general question of whether technology works or not. Findings have confirmed previous results and provided meaningful insights with regard to specific pedagogical approaches that are successful in improving student performance. The general analyses are in line with the findings of the overall M-A (Tamim et al. 2014), indicating the importance of cognitive support tools for successful learning. In addition, results further suggest that moderate intensity and complexity of technology use works better than oversaturation.

A current M-A provides some input regarding pedagogical strategies that work more effectively for educating preservice teachers. Particularly speaking, provision of adequate and specific feedback to students in technology-supported environments greatly increases the impact of technology use on student performance. The resulting average effect size of 0.75 translates into a 27-percentile gain for average students in the experimental group compared to those in the control group. The gains are significant and the implications are clear. Instructors need to incorporate feedback in their technology-enhanced instruction. Another pedagogical approach for successful use of technology in educational contexts is problem-based learning (PBL), where the average effect size of 0.56 indicates a 21-percentile gain in student performance.

Finally, one of the most interesting pieces of evidence in one study pertains to the importance

of training in successful technology integration in postsecondary education. This is in striking contrast to the belief that the newer generation of students is so technologically savvy that they do not need additional formal training.

Tablets for Teaching and Learning

The presented M-A addressing tablet use in educational contexts provided findings that indicate a moderate-strength average effect size of tablet uses on students' outcome measures. Moreover, higher effect sizes have been achieved when the devices are used in student-centered contexts. Of important relevance to academics and instructional designers is the implication that the impact of tablets on students' performance is amplified when it is used with a particular pedagogical framework such as collaborative work and project/problem based learning.

As for the qualitative literature review, tablets seem to be garnering positive perceptions about their effectiveness within educational contexts. When specifically questioned, the effectiveness of the devices was noted to be higher for particular tasks and when used with a student-centered pedagogical approach.

Concluding Remarks

In conclusion, three particular outcomes of this review of M-As that are important for research and practice are as follows:

- Technology alone, no matter how advanced, sophisticated, and fashionable, hardly works beyond its “novelty effect” in the absence of the other operative consideration – “educational.” Well-thought through instructional design and effective pedagogical strategies (e.g., interaction treatments designed for collaborative work, elaborate feedback) provide the substantial value-added that transforms whichever technology is adopted – including tablets – into technological tools that are advantageous for teaching and learning.
- Blended learning, which can combine the best qualities of face-to-face and online instruction, appears to offer a viable teaching/learning option for applying educational technology to

achieve its maximum benefits for learning. Nevertheless, this outcome is still to be further substantiated by both primary research and meta-analytical reviews. Beyond the practical advantages of blended learning, it is necessary to know how to combine the best of the face-to-face world with the best of the online world.

- In-time technology training for teachers and students is of high relevance and importance for the successful integration of technology within educational contexts. The belief that simply providing teachers and learners with the latest technology will transform the educational process has been shown by a range of researchers to be a misconception. For teachers, mere technical training does not transfer to pedagogically appropriate utilization of technology for teaching and learning. As for students, their familiarity and ubiquitous use of technology in their daily lives does not imply that they will be able to successfully use it to attain expected learning outcomes.

Q

Qualitative Methods, Lesson for Information Systems Researchers

Maria Mutudi, Monica Nehemia and Tiko Iyamu
Department of Information Technology,
Cape Peninsula University of Technology,
Cape Town, South Africa

Introduction

Research methods are regarded as tools or vehicles that are used in a research study to achieve its objectives. Patten and Newhart (2018) consider research methods to be building blocks of scientific inquiry that facilitates the acquisition of systematic knowledge. Research methods can thus be seen as being comprehensive and complex in their different applications in various subject areas (Walliman 2015). According to Davies and Hughes (2014), there are two main types of research methods, namely qualitative and quantitative research. However, Griensven et al. (2014) argue that the two types can be combined and also considered to be a type of research method called “mixed method.”

Even though this study is not about comparing both research methods, it is necessary to point out some of the differences with the purpose of putting the methods into perspectives. Qualitative methods differ in many ways from quantitative methods. However, the rigor required for

analyzing quantitative data is also required in qualitative methods, but with greater challenges because even though the analysis is rigorously conducted, it is done without the help of any mathematical rules (Hammarberg et al. 2016).

Quantitative methods are of an objective nature, based on numerical data that is measured or statistically analyzed (Bambale 2014). According to Clarke and Collier (2015), quantitative data is collected through a systematic approach with its focus being to answer questions of how and how much about a specific phenomenon. Biswas and Muthukkumarasamy (2017) state that in quantitative research methods, there is an emphasis on identifying theories, hypotheses, and then testing and measuring them. On the other hand, qualitative methods give emphasis to the individual’s perspectives, personal opinions, and experiences (Cope 2014). Differing from opinions about quantitative methods, Hammarberg et al. (2016) assert that qualitative methods are of a subjective nature, thus focusing on an understanding of the individual’s viewpoint about a phenomenon being studied. According to Beail and Williams (2014: 85), qualitative methods “form the foundation of many areas of theory and evidence in the physical and social sciences.” When applied strictly and carefully, qualitative methods also form the scientific foundation of critical subjects (Palinkas 2014). According to Hammarberg et al. (2016), there are some subject areas where it is critical to get an understanding of what the phenomena mean to

each individual or group rather than the counting and measuring of statistical numbers. This kind of understanding is achieved in many subject areas only through the use of qualitative methods which involve a clear understanding of why things happen the way they do (Palinkas 2014; Hammarberg et al. 2016).

Despite the endless number of benefits that the qualitative methods present, there is evidence of its many challenges. Haahr et al. (2014) highlight ethics as one of the challenges that is often experienced when using qualitative methods such as conducting interviews, particularly when close relatives and colleagues are the participants. This type of challenge can be attributed to the fact that the researchers interact directly and personally with the participants, sometimes offering their own meaning (Sanjari et al. 2014). From a different perspective, Saunders et al. (2015) assert that it is very challenging to anonymize qualitative data and yet still maintain the integrity of data, especially in delicate contexts.

Even though many challenges have been highlighted in the literature about qualitative methods in IS research, problems linger on, making some postgraduate students avoid qualitative methods and opting for an alternative (Marshall et al. 2013). This is a critical problem in that some students' avoidance of the methods is not based on merit or suitability, which sometimes makes their research more complex which may affect the outcome as well. Many scholars acknowledge how difficult it is to reduce the complexities in the IS field by using quantitative research (Goldkuhl 2012). Thus, the objective of this study was to examine the challenges of qualitative methods in IS research, and through a model propose a solution.

For the purposes of flow and clarity, it is necessary to explain how this entry is structured. The entry consists of four main sections. The entry is introduced in the first section where the objective is also presented. Guided by the objective, existing literature relating to the subject are explored in the second section. The complexities that are often experienced in information systems (IS) research are discussed in the third section.

Thereafter, a conclusion is reached, completing the section.

Existing Literature

Information systems and technologies (IS/IT) are used to automate and manipulate various processes and operations for individuals and organizational purposes (Stair and Reynolds 2013), which can assist an organization toward achieving its strategic mission. With the use of IS/IT for various purposes, employees in an organization are classified as end-users (Iyamu and Kekwaletswe 2010), making both people and IS/IT equally important in an environment. Callon (1986) explains from asymmetric position that both humans and nonhumans are equal within a network. Our inevitable assertion leans toward the fact that IS/IT artifacts neither exists by themselves nor operate in a vacuum, without humans or their effects on human processes and activities (Iyamu and Shaanika 2018). Within this context, research has increasingly been carried out in the areas of IS/IT over the years, to evaluate, assess, and manage the development, implementation, and post-implementation activities in organizations (Erickson 2012). Also, owing to IS/IT connectedness with human efforts, qualitative methods have popularly been selected in IS research, as explained by Walsham (2018).

Some time ago, Myers and Avison (2002) suggest that qualitative research methods originate from the social science field, with the objective of enabling a researcher to study social and cultural phenomena. Today, the position has not been disputed. Reference has been made here to the origin of the methods so as to draw attention to and connect the facts with some of the challenges that are currently experienced by many postgraduate students. The qualitative research method is often employed in IS studies to interrogate the influence and impact that human perceptions and nontechnical aspects have on organizations (Iyamu 2015). Without undue controversy, Kornbluh (2015) explains that the aim of many researchers that apply qualitative methods is to develop an understanding of the

phenomenon by examining the ways in which participants experience, perceive, and make sense of their lives.

Increasingly, many researchers have applied qualitative methods in their studies to address various problems and objectives, such as the impact of organizational structure on the implementation of IS (Indeje and Zheng 2010) and determining the critical success factors of people that influence the successful implementation of IS/IT (Aziz and Salleh 2011). Kornbluh (2015) conducted a study to establish the challenges of trustworthiness in qualitative research. The study tried to establish consistency in selecting trustworthy respondents who would not be biased in the data provided owing to their positions. Another challenge with qualitative methods is providing justification for some of its techniques, such as sampling (Robinson 2014). The respondents, number of respondents, and the number of interview questions are referred to as sample size, which can be a challenge for some researchers (Marshall et al. 2013). From the results of their research, they have found that there is little rigor in justifying sample size and no consistency applied when determining sample sizes for studies where the case study approach or grounded theory is followed.

The use of qualitative methods has been a challenge for many IS researchers over the years. Dickson-Swift et al. (2007) claim that some challenges are unique to qualitative research. Marshall et al. (2013) suggest that qualitative research is time-consuming and mentally exhaustive when compared to other forms of research. Qualitative research lacks guidelines on the perspectives of data collection and data analysis, and the processes are subjected to the discretion of the researcher. Yin (2009) argues that since the processes are not structured and consistent, it puts a lot of pressure on the intellect, ego, and emotions of the researcher. Owing to a lack of standardized guidelines, based on their know-how, researchers employ methods and techniques to achieve the objectives of their studies as they deem fit. Puebla and Davidson (2012) postulate that there is no right way to approach qualitative research, but there are different ways that qualitative research

can be approached in order to achieve its objective.

Since qualitative research methods are primarily concerned with an understanding of people (Myers and Avison 2002), researchers are sometimes entrusted with private and sensitive information or perceptions of the participant's views, which could be a challenge to some researchers, thus making it necessary, but difficult, to manage the information. Subsequently, it is expected from the researcher to treat the collected data with confidentiality, which may be regarded as too much of an effort to accomplish by some researchers. Dickson-Swift et al. (2007) explain that researchers have the responsibility of facilitating the management of participants' disclosure of confidential information in the process of their studies. However, this can be achieved by establishing trust between the researcher and the participant (Mutudi and Iyamu 2018).

Even though Booth and Booth (1994) also propose that researchers need to develop a level of trust so that participants are comfortable about sharing their stories, it remains a challenge to do so. However, in order to establish trust with the participants in a short time, some researchers disclose private information about themselves to establish comfort and trust with the participants. Dickson-Swift et al. (2007) observe that the researcher tries to be innovative about gaining trust. Results from their study suggest that some researchers admit that self-disclosure was a conscious effort in order to enhance the relationship between them and the participants.

Qualitative researchers are faced with the challenge of being too subjective during data collection and data analysis. Their subjectivism can distort the data collected during transcription and analysis, if not managed properly. In an effort to mitigate this challenge, "member checks" are conducted (Kornbluh 2015). Member checks are the processes whereby a researcher validates findings with participants in order to ensure that the participant's intended meanings reflect accordingly, which allows for the detection of personal biases of the researcher (Marshall and Rossman 2010) and this process of validation can be time-consuming and tedious.

Understanding the Complexities

The analysis of the existing literature helps us to form and gain a different understanding. From the analysis, four critical challenges were found, which included formulating interview questions, conducting an interview, and selecting respondents and ethical challenges. The challenges are diagrammatically represented as shown in Fig. 1. By means of Fig. 1, the connection between the challenges is illustrated, to indicate how they influence one other in the application of the methods.

Formulating Interview Questions

The interview is one of the most popular techniques that is used to collect data from the perspective of qualitative research methods (Mikkonen et al. 2015; Firth et al. 2016). It is well documented that data were the most critical aspect of research primarily because they influence the quality of the research positively or negatively (Rimando et al. 2015). Thus, it is crucial to formulate appropriate interview

questions that are used in collecting data. This is one of the reasons why this requires attention as aspiring researchers and postgraduate students continue to encounter challenges in qualitative research during the data-collection process (Iyamu and Shaanika 2018). The challenges begin with the formulation of interview questions. These can be attributed to the fact that some aspiring researchers and postgraduate students tend to be too academic when phrasing the interview questions. As a result, some of the questions come across as a test or examination of knowledge, which becomes difficult for some participants to answer (Montoya 2016). This reduces the interviewee’s participation in conversation, which affects the quality of the data, as the richness of the data is influenced by the ability of the researcher to interrogate the subject by getting interviewees to share more of their views and opinions (Iyamu and Shaanika 2018). Therefore, experience is required from the researcher in order to formulate questions in an easy and understandable way for the participants to embrace (Rimando et al. 2015).

Qualitative Methods, Lesson for Information Systems Researchers, Fig. 1 Complexities of qualitative methods in data collection

The type of interview question that is formulated influences the kind of interviewees that are selected to partake in the study. As shown in Fig. 1, it is necessary to have a basic idea of the unit of analysis in formulating the questions (Montoya 2016). According to De Vaus (2013), units of analysis are categories of sources of information about the phenomena being studied. Based on the formulated questions and the pre-determined units, the researcher selects the participants that have knowledge about the subject. Presumably, they are able to provide data that are rich enough to accomplish the objectives of the study (Curry et al. 2009). For example, when investigating the impact of IS on users in an organization, the interview questions should be formulated in sets that focus on different units. The first unit attempts to address the deployment of IS and the second, the perceptions of the users who are from the business units, respectively.

Selecting Participants

The type of participants that are selected in a qualitative research is critically important. However, it is often a difficult task for many post-graduates in that qualitative research rejects a random selection of participants (Gentles et al. 2015). Qualitative researchers experience different challenges at each stage of the methodology, for example, challenges experienced during data collection are different from the challenges experienced in data analysis. Before starting with data collection, a researcher needs to plan and have an idea of the kind of participants who should take part in the research. This will be respondents that are part of the research problem and give insight and clarity on the subject matter. Primarily, this is because it is nearly impossible, from random sampling, to determine the people who are knowledgeable about the subject (Marshall et al. 2013), which also makes the approach more difficult to justify. A researcher needs to select respondents that are knowledgeable about the subject matter, thus having confidence that the interaction will result in rich data that can be used to fulfill the objective of the research. Not selecting the most appropriate respondents for an interview can lead to collection of poor data that can impact on the

objective of the research negatively. Along the same line of argument, Curry et al. (2009: 1445) claim that “the aim is to identify information-rich participants who have certain characteristics, detailed knowledge, or direct experience relevant to the phenomenon of interest.”

It is important that participants in empirical studies are selected for a specific purpose. According to Palinkas et al. (2015), the participants of a study are selected based on predefined criteria by the researcher. Thus, as shown in Fig. 1, there is a two-way communication between the participants selected and the researcher conducting the actual interview in that they both influence one other. Such communication requires some degree of experience to avoid “silent” intimidation, which sometimes can happen between some aspiring researchers and interviewees. From another viewpoint, the relationship between the researcher and interviewee allows the latter party to freely share his or her experience in the deepest form to the extent of sometimes answering some questions even before they are posed. At this point, the responsibility and ability lies with the researcher to have the right attitude and open mind in managing the process to his or her advantage (Curry et al. 2009).

Conducting Interviews

There are different types of techniques including a questionnaire that could possibly be used to collect data in a qualitative research. The in-depth interview is one of the more popular techniques that can be used in collecting data from a qualitative method perspective, a technique which Curry et al. (2009) define as typically one-to-one interaction between a researcher and a respondent. The in-depth interview allows the researcher to probe for more clarity if needed. According to Iyamu (2015), qualitative research is interrogative and the researcher is allowed to get clarification on questions such as who, why, what, when, how, and where. However, probing is not simple to execute, because knowing precisely when to probe for more clarity is a challenge for some researchers, which is a skill a researcher acquires with time and experience. Yin (2009) posits that an experienced researcher will be able to take

advantage of unexpected opportunities during data collection. These opportunities, which could add value to the objective of the research, can easily be missed by an aspiring qualitative researcher.

Within the postgraduate community, there is a narrative that conducting an interview is complex and requires highly skilled researchers. Curry et al. (2009) suggest that the ability to use probes and follow-up questions in order to provoke more responses requires a skillful understanding of the process. Curry et al. (2009) add that it is important for researchers not to create a situation that would not discourage respondents from freely expressing themselves. Most importantly, this is to mitigate against a situation that could discourage up-and-coming researchers who wish to engage with respondents or to undertake an in-depth interview at some stage in their careers.

A code of conduct is another factor that influences the use of the interview technique for data collection. For various reasons, interviews are guided by a code of ethics which differs from one environment to another. According to Senter et al. (2018), a code of ethics is a set of rules and principles that serve as a guide for ethical behavior within a particular environment or organization. However, each environment has a specific code of ethics which is influenced by factors such as culture and goals (TeRiele and Brooks 2013). It becomes challenging for some postgraduate students and aspiring researchers in their first few experiences to deal with ethical issues in the different environments where they are to conduct the interview.

Ethical Challenges

Dealing with the challenges discussed above is not an easy exercise in many cases, especially when there are ethical issues involved. Sanjari et al. (2014) state that ethical challenges are one of the major challenges when using qualitative methods. According to Saunders et al. (2015), the temptation to be unethical under difficult situations is greater in qualitative research. For example, in a situation where it is difficult to get individuals to participate in a study, a researcher can be tempted to unethically convince individuals to participate in his or her research.

According to TeRiele and Brooks (2013), paying individuals to participate in research where payment is not a custom of the participants, may be seen as an inducement, which can therefore be considered unethical. There are other ethical challenges, such as inconsistency and a lack of transparency. Gentles et al. (2015) argue that, irrespective of the reason, it is unethical to dismiss an individual after his or her offer to participate in the study voluntarily has been accepted. Such action may be considered to be morally offensive for some individuals in certain environments. Therefore, the researchers may find themselves in an ethical dilemma that is very difficult to solve.

Sometimes, a researcher may have a preconceived outcome in mind. This preconception could develop during the literature review or from exposure to the subject matter. Consequently, researchers can become desperate if their preconceived outcomes are not met through the interviews that are conducted. Researchers can thus be tempted to act unethically in order to fulfill their preconceived outcome. According to Myers and Avison (2002), the researcher's preconception affects the collection of data, in that the researcher may pose questions that are aimed largely at addressing what they wish to find out.

Ethical challenges are found at every stage of research. As demonstrated in Fig. 1, ethics is the factor that influences the way interviews will be formulated, the way the participants will be selected and how the interview will be conducted.

Conclusion

This entry will be of particular interest and benefit to both postgraduate students and aspiring researchers from two main academic standpoints, namely theoretical and practical. From a theoretical standpoint, this entry can guide researchers to avoid pitfalls which others have fallen into, in the process of collecting qualitative data for their studies. An understanding of this entry through the discussion of its complexities can make the use of qualitative methods look easy in practice. This entry can also be used as teaching and learning material by academics, thus contributing to

the body of knowledge through its addition to existing literature. Even though so much work has been done on qualitative methods, this entry brings a different dimension based on its specific focus on challenges that develop into complexities, which could be considered as a theoretical contribution in the field of IS.

Introduction

Computers have had a presence in school classrooms for 50 years now, and digital technology has advanced considerably over this time. How have the ideas behind their use to aid teaching and learning developed over the same time period?

This entry will focus on the reasons and intentions for the use of technology as one element of the learning environment in schools. It will discuss the key issues of pedagogy which relate to the organization of classroom learning and examine the variation in pedagogical rationales for IT during the past 25 years.

Pedagogy and IT

Approaches to teaching have often been characterized as a dichotomy: the transmission of

knowledge or the facilitation of learning. However, Alexander (2008) rejects this simplistic categorization and suggests that teaching can be viewed as:

- Transmission
- Initiation
- Negotiation
- Facilitation
- Acceleration
- Technology

The key variables in these perspectives on teaching practice are organization, discourse, and meaning. These are based on primordial values concerning human relationships: individualism, community, and collectivism. They vary over time and across different cultures according to beliefs “about the extent to which knowledge is open or bounded, provisional or contestable; about how ideas should be handled; about the kinds of authority that teachers and curricula embody and the extent to which they can be questioned; about how individuals and groups should relate to each other; about the balance of individual autonomy and collective responsibility; about what counts as successful learning; and about what it means to be educated” (p. 39). Such fundamental issues concerning teaching will have profound effects on intentions for IT in the classroom. For instance, the variation in the ratio of structured talk to writing by learners in different pedagogical traditions (Alexander 2008) may be

of particular significance for the use of technology.

Pedagogy is not just about the teacher, of course, and there are related variations in views of learning: children may be seen as imitators, recipients, thinkers, and knowledgeable (Bruner 1996). Again, teachers' views of their students will strongly influence their deployment of IT resources and the role IT plays in their relationship with learners. The intentions for the use of technology are likely to be quite different in a classroom culture based on interaction between learners compared with one based on individual study and interaction only with the teacher.

Two key concepts developed by Shulman (1986) have been used in many studies of teacher thinking: pedagogical knowledge and pedagogical reasoning. Pedagogical knowledge comprises a number of interrelated aspects, including general pedagogical knowledge (the principles a teacher uses in managing learning, based on their beliefs and values) and pedagogical content knowledge (how the teacher represents subject-specific ideas for students to learn). This framework thus acknowledges the variation of pedagogy according to the subject taught as well as according to general views of teaching and learning. It has been developed further to incorporate IT into teacher thinking, and Mishra and Koehler (2006) devised the TPACK framework to represent the complex influences that technology can have on each of the aspects of teacher knowledge.

Pedagogical reasoning represents the process of transforming knowledge of subject content into knowledge for teaching. It includes the planning and preparation that take place in advance of lessons and the dynamic rethinking of activity which takes place in the classroom. Webb and Cox (2004) extended Shulman's original ideas to produce a framework for pedagogical practices relating to IT use which involves the key idea of "affordance" (Gibson 1979). This framework takes account of teachers' beliefs and is more sensitive than TPACK to the decisions and actions taken by teachers and learners when using IT and other media as aids to learning.

The terms affordance and constraint have been used widely to analyze how factors in the

environment influence activity (see, for instance, Kennewell 2001 and Webb 2005). They are valuable tools for the analysis of educational activity, particularly where students carry out actions in pursuing certain goals which are generally set by the teacher. Learners have options concerning their actions in pursuit of these goals and make decisions based on the affordances and constraints offered by the learning environment. While some of the features of the activity setting will be fixed, many others can be manipulated, and term orchestration has also been used widely over recent years to characterize the manipulation of the environment's affordances for learning (Prieto et al. 2011).

At a general level, "orchestration refers to how a teacher manages, in real time, multi-layered activities in a multi-constraints context" (Dillenbourg 2013). More precisely, it concerns the purposeful arrangement of affordances and constraints for students' actions during a task in order to bring about learning from their actions (Kennewell 2001). It is not only the teacher who can orchestrate activity; learners themselves can manage their environment to some extent. Orchestration can range from teacher intervention during collaborative activity using tablets in a primary school mathematics lesson (Prieto et al. 2011) to students seeking help from teaching assistants in a university Physics class (Dillenbourg 2013).

Five key elements comprise the orchestration of learning: design/planning, regulation/management, adaptation/flexibility/intervention, and awareness/assessment (Prieto et al. 2011). In a formal setting, whether in a classroom or online, a teacher will typically:

- Design a task and plan the resources to be available to students.
- Discuss the concepts and techniques relevant to the task.
- Give procedural instructions.
- Explain outcome expectations.
- Monitor student activity and intervene with individuals or groups: adding or changing resources, instructions, or expectations; answering and asking questions, providing prompts and explanations.

- Evaluate outcomes, assess learning, and provide feedback.

Teachers will aim to align the affordances of the environment to the intended learning objectives. Students may also manipulate the affordances and constraints to help achieve the task goal, particularly by using peers to help explain ideas, clarify instructions, and locate resources. This may inhibit the intended learning, however – for example – if one student just copies the work of another or focuses merely on completing the task in the simplest manner (Kennewell et al. 2008).

An orchestration perspective provides a means of analyzing the role of digital technology in learning and how it changes with increasing technological advance and maturity of implementation. In characterizing how learners' actions are facilitated together with how their actions may be restricted, it offers a more sophisticated framework for studying the way in which learning is managed than the simple idea of balance of control. Furthermore, it provides valuable insight into teachers' intentions for the use of IT.

Analysis of Rationales for IT

In the light of the variations in pedagogical belief and practice, it is not surprising that the role of technology in teaching and learning has been seen differently at different times and in different cultures. Early in the development of digital technology, two important classifications of IT use were posited:

1. Instructional, revelatory, conjectural, emancipatory – Kemmis et al. (1977)
2. Tutor, tool, tutee – Taylor (1980)

These ways of analyzing of IT's pedagogical role are similar; the second has the virtue of simplicity and has perhaps had the more influence on subsequent research and practice. They both match the pedagogical classifications to some extent; tutor/instructional corresponds to teaching as transmission and children as

imitators/recipients; tool/emancipatory corresponds to teaching as facilitation and children as knowledgeable; tutee/conjectural corresponds to teaching as negotiation and learners as thinkers; and revelatory corresponds to teaching as initiation.

More generally, three broad forms of rationale have been employed since the early days of IT in schools, and each can be characterized by its relation to orchestration.

1. *Replacement*: IT is intended to adopt some or all of the roles traditionally carried out by the teacher and students. This may involve the technology being programmed to orchestrate the learning environment (e.g., managing the allocation of tasks for the learner, providing repetitive practice with feedback) or merely being one resource available to the teacher and/or student as part of the environment which the teacher orchestrates (e.g., engagement of learners through a visual or interactive display).
2. *Augmentation*: IT is intended to adopt new roles which traditionally the teacher and students have not carried out. This requires new forms of orchestration by the teacher and/or learners (e.g., simulation).
3. *Transformation*: IT is intended to facilitate a fundamental change in the process of teaching and learning, particularly enabling learning as participation in knowledge development rather than reception of knowledge. This shifts the orchestration of the environment to the students (e.g., word processing for drafting/redrafting, modelling for testing ideas).

The ways in which these broad rationales have underpinned practice at different times can be traced in the contributions to the World Conference on Computers in Education (WCCE), for example. The themes selected for these conferences over the past 25 years reveal changing intentions:

- Freedom for learners (WCCE 1995 – Liberating the Learner), suggesting a reduction in orchestration by the teacher

- Collaboration/connectivity between learners (WCCE 2001, *Networking the Learner*; 2013, *Learning While We Are Connected*), suggesting the facilitating of orchestration by learners
- Effectiveness of learning environment (WCCE 2005, *What works?*; 2009, *For a Better World*), suggesting a focus on outcomes rather than pedagogy
- Involvement of all in learning (WCCE 2017 – *Tomorrow's Learning: Involving Everyone*) – confirming the shift to learner orchestration

Most of these reflect a rationale of transformation. In order to explore these intentions more closely in relation to orchestration, however, it is necessary to examine contributions more closely (Kennewell 2017).

The first WCCE to have a theme was in 1995, when there was clearly a desire to use digital technology to help give students more influence over learning situations. The theme of “liberating the learner” was interpreted quite cautiously, but the idea that the teachers’ control could and would diminish in the digital environment ran right through the contributions analyzed. Consequently most papers were concerned with how this more student-centered scenario might be implemented in terms of technological design. The focus on orchestration in the analysis has brought out a variety of ways in which the management of learning might be shared among different participants: teachers, students, and the technology itself. The key issue for implementing technological assistance in any setting is not what the balance of control should be but what contribution each of the participants can best make to the processes involved in orchestration. It did not seem in 1995 that technology was at the stage of making a large, active contribution to either design/planning, monitoring/intervention, or assessment/feedback, and for most contributors, it remained a tool and resource for the human agents involved.

A number of developments since 1995 have made a substantial impact on teaching and learning. These include:

- Learning management systems: these can be accessed anytime and anywhere, but despite the name, they do not actually orchestrate learning themselves but rather provide a structure and features which support management of resources by teachers but impose significant constraints on learners (Bennett 2011). While these have been embedded widely in higher education institutions, their adoption in schools has been much less than was anticipated a few years ago.
- Interactive whiteboards: these also provide many features which can afford and constrain classroom activity but have been largely used by teachers to facilitate their traditional approaches to orchestrating resources and are valued for their effects on engaging learners (see, e.g., Kennewell et al. 2008). These devices have been very widely adopted in schools but have had less influence in higher education.
- Web2 and social media: structures such as blogs, wikis, news broadcasting, and social networking have all been appropriated widely for educational purposes; they have affordances for interaction over distance and time but pose considerable challenges for distributing the orchestration between teachers and students (ASHE 2014), and perhaps because of this, they do not yet seem to have been adopted widely in schools.
- Mobile learning and 1:1 classroom devices: again, they clearly offer affordances for action which are flexible in place and time and also for individualized learning. The distribution of orchestration is again a challenge, and although in many institutions it is the norm for each student to have a computer in the classroom, their use in schools is often tightly constrained by the teacher, and students are not allowed to use their own devices because of potential distractions (Weigend 2017).
- Gamification: this approach represents a particular mode of orchestration in which the activity setting takes the form of a game in some way. The constraints are managed by the computer according to the rules of the “game,” and the affordances for action are

orchestrated largely by the learners. Perhaps for this reason, game-based learning is seen as particularly motivating for students (Caponetto et al. 2014). As the active role of the teacher may be quite small, it is particularly suitable for use outside the classroom.

In each of these cases, it seems that the degree of adoption of the technology in different sectors is directly correlated with the fit between the form of orchestration supported by the technology and the traditional pedagogy of the teacher. In other words, IT is used when it helps the teacher to do what they already do. The process of pedagogical reasoning has been adapted, but it does not seem that most teachers have developed their knowledge and beliefs to incorporate IT.

The most recent WCCE in 2017 adopted the theme “Tomorrow’s Learning: Involving Everyone.” Involvement seems to require more than just access to teaching and resources; it suggests that our aim for all should be active participation in learning.

A number of contributors to WCCE 2017 addressed this issue. Some identified the nature of the task as an important factor in motivating learning. The creation of a worthwhile product was seen as particularly significant, particularly if this presented a challenge to learners, although such challenges must be seen as realistic targets by learners, and an alternative strategy involving finding, trying out, and reflecting/discussing is also effective. Digital technology can support game environments which engage learners actively with learning tasks within and beyond the classroom and increase students’ interest in the learning process itself rather than just the grades achieved. It can increase the “learnability” of topics by positioning students positively in relation to difficult concepts. While a digital learning environment may be designed for active learning or active participation, the affordances of the technology may not be sufficient on their own to sustain student engagement, and many learners need the support of the teacher or others, either in the classroom or online (Kolbaek and Nortvig 2017). For learners accustomed to using technology on the move, physical activity with mobile

devices outside the classroom also aids engagement in learning (Weigend 2017).

The idea of “freedom” had not entirely disappeared; for some contributors, choice was seen as an important factor in involvement of learners. Being able to select a theme of personal interest to work on was motivating for students, although there was some concern that students might only be motivated by themes in which they were personally interested. Freedom to use heuristic methods in problem-solving was supported by digital environments, a situation which is reminiscent of the vision for LOGO classrooms in the 1980s which had largely disappeared in 1995.

Conclusion

IT changes not just what is orchestrated but the nature and location of orchestration itself. The challenge of progressing from provision of access to teaching toward engagement and participation in learning can be informed by the analysis above. There is overwhelming evidence that digital technology motivates students to participate in activity; the difficulty comes in stimulating students to focus on learning from that activity. Teachers are generally adept at designing and preparing environments that offer affordances for all students in their charge. The first stage in the development of active participation involves being able to judge when digital technology can provide more or better affordances for learning. But IT environments provide affordances for many other actions, and in order to avoid distractions, students must first adopt the teacher’s intention, not just for task completion but for achieving the intended learning outcomes.

The second stage is for students themselves to learn to orchestrate affordances and constraints for learning: this is the essence of “intentional learning” (Bereiter and Scardamalia 1989). Effective learners do this already, but many students do not seek – or are prevented from using – prompts from peers, new resources, or even familiar tools. Digital technology can support this sharing of orchestration (see, e.g., Turner 1995) which dealt with this idea explicitly, but some learners will

need support from teachers or other people (Saito 2017).

In this entry, the changes in rationale for the use of IT in the classroom have been characterized in terms of teachers' pedagogical thinking and in particular their intentions for the orchestration of affordances in the classroom environment. This has shown that the developing affordances of IT may not be aligned with teachers' rationales which have their roots in pedagogical beliefs.

Where teaching is viewed as transmission or as technology, the potential of IT is not likely to be fully exploited. This has implications for policy-making, professional development, and resource provision in all parts of the world. A transformation rationale means a fundamental change in pedagogical perspective to teaching as negotiation or facilitation, which cannot be achieved merely by providing more or better IT.

Introduction

A significant challenge for today's teachers is that they actively engage in teaching their content with today's technologies. This challenge recognizes that, with the rapid pace of new and more robust technological learning tools, teachers are at a

disadvantage because they have not learned with these technologies. Now, they must envision how these new technologies support learning of their content as well as which pedagogical strategies are effective in engaging students in learning with the technologies. They must identify, orchestrate, and manage different strategies and learning tasks in their content areas in order to effectively support students with twenty-first century critical learning skills. In other words, today's teachers must continue learning in order to guide students in learning for their tomorrow. Teacher educators thus are challenged to respond to this important question: How can today's teachers engage in learning about the technologies and about teaching with the technologies while they are actively teaching in their classrooms?

Teachers' knowledge for tomorrow is far more than just an understanding of the subject matter content. It ultimately necessitates a robust pedagogical knowledge along with knowledge for teaching with the vast array of technological

innovations. The task calls for what has been identified as Technological Pedagogical Content Knowledge (Angeli and Valanides 2005; Mishra and Koehler 2006; Niess 2005), otherwise referred to as TPACK (Thompson and Mishra 2007). TPACK as shown in Fig. 1 describes the transformation of teachers' knowledge at the center intersection of content knowledge, pedagogical knowledge, and technological knowledge to support teachers in the strategic thinking of when, where, and how to guide students' learning with technologies.

While the TPACK construct is recognized and supported by extensive research and scholarly work, teacher educators are faced with identifying appropriate professional in-service learning experiences to effectively reconstruct teachers' knowledge into a robust pedagogical understanding so that they understand and are able to guide students in collaborating and communicating as they engage in inquiry tasks using multiple technologies as learning tools. When determining

Restructuring Teachers' Knowledge for Teaching with Technologies with Online Professional Development,

Fig. 1 Representation of Technological Pedagogical Content Knowledge (TPACK) as teachers' transformed knowledge. (Reproduced by permission of the publisher, © 2012 by tpack.org)

appropriate instructional strategies for developing teachers' TPACK, Mishra and Koehler (2006) claim that:

There is no single technological solution that applies for every teacher, every course, or for every view of teaching. Quality teaching requires developing a nuanced understanding of the complex relationship, and using this understanding to develop appropriate, context-specific strategies and representations. (p. 1029)

Now, teacher professional development must be designed to guide teachers in reconstructing their knowledge, to engage in relearning, rethinking, and redefining teaching and learning as they know and learned it. Basically, they must confront their current conceptions to integrate technologies as learning tools in their content areas (Loughran 2002) to develop the reformed and reconstructed TPACK understandings.

An increasingly recognized educational setting for teachers' professional learning experiences is provided through online instructional avenues, providing increased access for many more teachers. Teacher educators must incorporate effective online learning experiences to reframe teachers' knowledge and this provision must happen today as the new technologies are evolving at an increasing rate. Teacher educators are, therefore, faced with multiple important questions as they consider designing new professional development instructional venues. What are the important features for an online learning trajectory for guiding teacher educators in redesigning their learning experiences? What online learning trajectories are not only useful for engaging teachers in knowledge-building communities but also provide them with an understanding of the pedagogical challenges for establishing these similar communities in their classrooms? How can teachers gain classroom-based learning experiences where they apply their learning about teaching with technologies? What structure might be used for an online learning trajectory for teacher education?

This case study examined a researcher-conjectured and empirically supported learning trajectory instructional approach to enhance in-service teachers' TPACK for teaching with a

technology new to them. The primary question for this study was: How might a TPACK learning trajectory support a blend of teachers' online communities of learners with practical teaching experiences so that they have the opportunity to apply their TPACK in ways that advance their knowledge toward a TPACK-of-practice?

Theoretical Framework

Reconstructing in-service teachers' knowledge to reflect the ideas described by TPACK requires systematic inquiries about teaching, learning, subject matter and curriculum, and schooling, much as that described in Cochran-Smith and Lytle's (2001) conception of "knowledge-of-practice" as a "transformed and expanded view of what 'practice' means" (p. 276). This conception assumes that knowledge is "socially constructed by teachers who work together and also by teachers and students as they mingle their previous experiences, their prior knowledge, their cultural and linguistic resources, and the textual resources and materials of the classroom" (p. 280). This conception of teacher learning necessitates incorporation as an inquiry community where reflection is a central component (Cochran-Smith and Lytle 2001; Loughran 2002; Schön 1983). The vision of TPACK can therefore be referred to as a *TPACK-of-practice*.

Borko (2004) describes a process for identifying high-quality teacher change programs, beginning with studies in a single site, exploring relationships between teachers as learners in a specific learning trajectory. Confrey and Maloney (2010) further describe a learning trajectory as a "researcher conjectured, empirically supported" description of an "ordered network of experiences" where students move from "informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time" (Confrey and Maloney 2010, p. 968). For the learning trajectory in this study, the teacher is the student in the instruction designed to move from informal ideas about teaching with technology through successive refinements toward a

reconstructed knowledge for teaching with technology. Thus, through purposeful design, this experience models the instructional strategies for teaching with technologies.

The researcher-conjectured unit design was supported by an empirically supported online learning trajectory (Niess and Gillow-Wiles 2013). The trajectory identified key instructional strategies through a social metacognitive constructivist instructional framework that described the tools and processes for driving the content development in an online asynchronous, text-based learning professional development. The study then examined the teachers' advancement in their TPACK-of-practice resulting from their experiences in a course that blended their practical experiences with their online community interactions.

Tools

Two key tools were incorporated in the asynchronous, text-based, online experiences – (1) a community of learners and (2) reflection. Learners in online experiences typically are required to make sense of new information in isolation with only asynchronous avenues for making connections with other learners and the instructor. Thus, a community of learners is an essential tool that supports the learners in communicating and interacting through discussions about the tasks and ideas being presented. This tool establishes a social presence through the community such that it functions as a knowledge-building community.

Multiple researchers have indicated that such a social presence establishes community member participation and educational experiences that result in meaningful learning, open communication, and group cohesion (Garrison et al. 1999; Garrison and Cleveland-Innes 2005; Hill et al. 2009; Kinsel et al. 2005; Rourke et al. 1999; Swan and Shih 2005; Sung and Mayer 2012). Garrison and Cleveland-Innes (2005) have explained the importance of engaging learners in active roles in online environments for establishing an understanding as they made sense of the new information and ideas. The community of learners provided a dynamic integration

of the social, cognitive, and teaching presences toward higher order learning, where they also claimed “the reflective and collaborative properties of asynchronous, text-based online learning are well adapted to deep approaches to learning (i.e., cognitive presence)” (Garrison and Cleveland-Innes 2005, p. 145).

Reflection provided a second important tool for the online learning trajectory. Critical reflection has supported the cognitive presence throughout the online learning trajectory. Learner engagement in reflection was supported in multiple ways, such as having learners prepare content reflective essays as well as reflective essays on their community engagement and providing peer reviews or other learners' work. In this study, the teachers used a TPACK reflective tool for guiding reflections of their progress with four TPACK components (Niess 2005) and their emerging TPACK development levels (Niess 2013).

Processes

The second primary component of the online learning trajectory included the support of processes for using the tools for learning. Two processes were helpful in the online learning trajectory for engaging the social and cognitive presences in the social metacognitive constructivist framework: (1) shared/individual knowledge development and (2) inquiry. As the learners engaged in the community of learners' activities, they shared their understandings of how they interpreted the ideas. As the discussions evolved through their interactions, the learner's individual knowledge developed. In relying on the primary trajectory tools (community of learners and reflection), the learners moved between group and individual knowledge-building where they created understanding that more clearly reflected a world view with respect to the course (Dunlap and Lowenthal 2014; Rienties et al. 2013; Swan 2001). Thus, their individual knowledge expanded beyond that which they were able to develop independently.

Another key process with the knowledge-building communities was the use of inquiry-

Restructuring Teachers' Knowledge for Teaching with Technologies with Online Professional Development,

Fig. 2 Model for restructuring teachers' TPACK-of-practice

based activities to support the learners in opportunities and experiences where they were engaged in negotiating their understanding of the content. The inquiry process engaged participants in constructing their understandings, where they took ownership of their learning, starting with questions and exploration leading to investigating worthy questions, issues, problems, or ideas. They asked questions, gathered and analyzed information, generated solutions, made decisions, and justified their conclusions. The resulting actions interwove multiple technologies, instructional approaches, and content topics through multiple units. Throughout the process, the participants consistently engaged in thinking and reflecting about the dynamic interactions among content, pedagogy, and technology that emerged from the tasks in their online learning experiences (Roberts 2002; Wheatley 1992).

Online Master's Degree Program in Mathematics Education

The online Master's program in Mathematics Education concentrated on the development of the teachers' TPACK-of-practice for teaching mathematics with technologies. Four specific

courses emphasized developing the teachers' TPACK-of-practice (as shown in Fig. 2).

Three courses (SED 520, SED 521 and SED 522) merged the teachers' thinking about Technological Knowledge (TK) with Technological Pedagogical Knowledge (TPK), Technological Content Knowledge (TCK), and Pedagogical Content Knowledge (PCK). SED 520 envisioned the use of multimedia technologies for twenty-first century mathematical literacy. This course engaged the teachers with key pedagogical tools and processes for learning with technologies with specific attention to learning through collaboration, reflection, inquiry, and shared/individual knowledge development. SED 521 considered digital image and video technologies for engaging students in higher order thinking in mathematics. Again, this course guided the teachers with similar pedagogical tools and processes as in SED 520 for learning with different technologies. SED 522 emphasized spreadsheets as algebraic reasoning tools. The emphasis was on solving mathematical problems using spreadsheet tools to design dynamic and dependable spreadsheets.

The fourth course, SED 594, blended online discussions with practical teaching experiences. Throughout this course, the teachers applied their accumulated knowledge as they designed,

implemented, analyzed, and reflected on their teaching of a technology-infused 5-day instructional unit in their mathematics classrooms. They gathered artifacts for their electronic portfolios for describing their instructional strategies and the tools and processes they used for guiding their students in learning with technologies. Their electronic portfolios demonstrated how they implemented collaboration, reflection, inquiry, and shared/individual knowledge development in their own classrooms as they integrated technologies for learning mathematics.

As they engaged in this practical experience, they used the online collaborative groups to discuss and explore different instructional strategies, tools, and processes for teaching with technologies. They cooperatively explored and examined new, reform-based instructional strategies – visible thinking, student discourse, grouping structures, and multiple representations for motivation and engagement. Toward the end of the course, the participants conducted peer reviews of others' electronic portfolios to improve the communication of the events and thinking.

The Study

This descriptive case study examined how practical teaching experiences blended with teacher-participants' inquiries through a community of learners influenced the participating teachers as they rethought, relearned, and redefined teaching of mathematics with multiple technologies. The course progression engaged them in inquiries about instructional strategies for teaching mathematics with technologies as they simultaneously engaged in systematic inquiry of teaching in their classrooms. The primary research question examined how and in what ways a practical experience of teaching a 5-day unit with technology combined with community collaboration in examining instructional strategies influenced the restructuring of their TPACK-of-practice. Nine (9) K-12 in-service teachers (eight females, one male; teaching elementary

(2), middle school (3), and high school (4)) agreed to participate in the study as they examined their teaching of mathematics with technology in their classrooms. All had taught more than 3 years, most between 4 and 8.

Data Sources and Evidence

Individual teacher case binders (Myers et al. 2003) combined their electronic portfolios, the online discussions from the community or learners' inquiries, and the final course reflective essays. Independent analysis of the case binders revealed patterns and themes in the discussions and reflections, capturing each teacher's progression and outcomes from the practical teaching experiences and the community collaborations. Each analysis documented the teacher-participants' knowledge progression with evidence of their TPACK-of-practice and thinking framed with respect to four TPACK components (Niess 2005) throughout the practical teaching experiences and tasks as well as the online collaborative discussions: (1) overarching conceptions about the purposes for incorporating technology in teaching mathematics; (2) knowledge of students' understandings, thinking, and learning in mathematics with technology; (3) knowledge of curriculum and curricular materials that integrate technology in learning and teaching mathematics; (4) knowledge of instructional strategies and representations for teaching and learning mathematics with technologies. Collectively, each participant's TPACK-of-practice was described and confirmed. The completed case binders clarified the nine descriptive case analyses while also validating the cross case themes from the electronic portfolios, online discussions, and the final essays considering a primary research question: What is the impact of the teachers' experiences in the online course that blends the teachers' practical experiences with their online community discussions (orchestrated by the researcher-conjectured learning trajectory) on their TPACK-of-practice?

Study Results

Analysis of the nine K-12 mathematics teachers' blended online experiences resulted in a clear description of the development in their TPACK-of-practice. The teacher-participants' experiences and reflections described how their TPACK knowledge was influenced as a result of their practices and discussions. Two representative cases (using pseudonyms of Allysa and Barbara) highlight the patterns within the diversity of their classroom situations. These analyses demonstrated how the blended course, through their classroom artifacts, expressions, and reflections, influenced the teachers' developing knowledge for teaching mathematics with technologies and ultimately reconstructing their TPACK-of-practice.

Allysa

Allysa was motivated to implement and examine new and different instructional strategies from her typical instruction – working with graphing calculators and taking advantage of small group work. Prior to this experience, her primary instructional mode was teacher-centered but this teaching experience provided with the opportunity to test more the student-centered instructional strategies that she had been experiencing in her online courses. Through her video analyses of her teaching, she observed that having students working in groups provided opportunities for the students to share ideas; she noted how these opportunities enhanced the students' engagement and learning. "Through the video analysis and my own reflections, I felt I did witness students using discourse." Through the variety of opportunities for reflections in this blended online course, she concluded that she wanted to move to more student-centered strategies and she wanted technology to be part of that effort as noted in this comment:

The strategies of grouping, problem solving, questioning, and student discourse all allow the

learning environment to be centered on students who are actively engaged. . . I want to use more technology-centered activities. . . Technology must be integrated using instructional strategies; on its own, it is not an instructional strategy

The combination of the online discourse with other teacher-participants as they investigated and discussed the various instructional strategies allowed Allysa an opportunity to examine different instructional strategies when implementing the technology in her instruction. The blended experiences (discussion and teaching) supported her in recognizing and accepting the importance of student-centered strategies and group work.

Barbara

Trying new ideas, such as those in Allysa's case, was also seen in Barbara's case as she, too, wanted to go beyond the technologies to enhance her knowledge beyond those she had previously used with her students. Barbara used the blended course to integrate multiple technologies for teaching mathematics; in particular, she was interested in using technologies that supported communication, collaboration, and inquiry around the mathematical ideas. As she said, "Prior to this year, I have not had much experience with student-centered, hands-on, technology-rich, discovery learning strategies." Thus, in this experience, she added multiple data collection probes to engage students in gathering actual data that resulted in generating exponential, logarithmic, and logistic functions. She recognized that integrating real-time data collection with spreadsheets and Google Docs for analysis provided her with an opportunity to conduct a deeper analysis of her instruction as she incorporated multiple different instructional strategies as to what she normally did in her primarily direct instruction classroom strategies. Barbara was particularly interested in strategies that involved whole group and small group discussions, inquiry learning, and real-world applications while taking advantage of the basic features of the multiple technologies. In the

videos of her teaching, she saw how the students “were engaged in discovery learning, brainstorming, technology-enriched lessons, discussion, collaboration, and other strategies.” She viewed how her students interacted, shared ideas, and demonstrated their understandings. This recognition underscored the importance of “being a guide rather than the sole provider of information” as she had more typically done in her teaching. Her community of learners’ discussions supported the implementation of these multiple strategies for more student-directed instruction. In particular, she noted that when engaged in discourse, the students were more confident and comfortable communicating their ideas to the class or their small groups. “When they get stuck on a problem, they talk it out and only turn to me for help if they cannot come to a common agreement.” Through this process, she recognized that she “learned that they can do more student-centered activities with the right amount of support.” She closed with a promise for her future planning: “I will remember this as I plan other lessons.”

Cross Case Analysis

These two cases clearly showed the impact of the blended course through the teachers’ classroom actions as they integrated technologies as mathematics learning tools. The research question for this study focused on identifying how this blended course experience provided a reconstructed vision of the teachers’ TPACK-of-practice. In all nine cases, the teachers recognized the value of incorporating student-centered instruction, an instructional strategy that dominated their online discussions but had not previously dictated their classroom instruction. The electronic portfolios provided clear descriptions of the classrooms, with pictures of the classrooms and students in action along with presentations and analysis of varying levels of student work. The multiple reflections prior to, during, and following each lesson revealed multiple opportunities for the teachers to think about and learn from their technology-infused lessons. The online discussions

became sounding boards for ideas, helping the teachers to think through the ideas, encouraging them to experiment with multiple technologies and instructional strategies as they taught the mathematics they had previously taught in different ways – thus examining their TPACK-of-practice.

The cross case analysis for all of the teachers exposed three themes from the blended coursework process.

1. *Throughout the practical classroom activities, the teachers were engaged in action research as they taught with technologies.* They examined and discussed various instructional strategies with their online colleagues while they considered how those instructional strategies added to their teaching, supporting student learning. They identified more student-centered discourse and grouping strategies as keys to teaching with technologies, where they guided or facilitated students in higher order thinking with the technologies.
2. *The teachers were engaged in reflective thinking about their teaching with the technologies.* These reflective actions helped them “think about how to apply the knowledge they received in their experiences for making changes in their instruction” (Dieker and Monda-Amaya 1995, p. 241). Throughout the blended course, the teachers’ reflections consistently provided opportunities to review, rethink, and rephrase their conceptions, connecting their instructional actions with students’ successful learning experiences. In essence, these experiences reconstructed their knowledge for teaching mathematics with technologies.
3. *The teachers used multiple artifacts as objects to think with while developing knowledge for teaching mathematics with technologies* (Papert 2005) *as they engaged in the reflective processes about their own teaching.* They gathered these multiple artifacts in their electronic portfolios and used the artifacts as a primary support system for their thinking and online discussions.

Conclusion

The learning trajectory for the design of the courses in the online Master's degree program provided an innovative pathway for an online progression towards restructuring teachers' knowledge with respect to a variety of teaching concerns. The results highlighted the importance of a selection of instructional tasks interwoven with specific pedagogical strategies holistically in guiding the teachers' interactions with new and emerging technologies. The trajectory framed the teachers' thinking about the role of technology in learning along with thinking directed toward students' thinking and understanding of the content with the technologies. The online instructional learning trajectory infused social metacognitive constructivist pedagogical practices that engaged the teachers in ongoing collaborations, interactions, and reflections as they examined teaching with technology.

The practical course provided opportunities for authentic inquiries into their practice in ways that challenged their knowledge-of-teaching with respect to specific teaching concerns. The online learning trajectory (Niess and Gillow-Wiles 2013) provided a social metacognitive constructivist framework for the online courses as well as the blended online practical course. The development of the electronic portfolios provided a valid and reliable process for observing the teachers' actions and thinking (Borko et al. 1997) and, thus, resulted in a rigorous examination of their teaching. The community of learners supported and challenged the teachers' thinking and reflection enhancing both shared and individual knowledge of teaching. The dynamic between building individual knowledge and shared knowledge in the instructional progression (Hodes et al. 2011; Yukawa 2006) was an important platform for building and restructuring the teachers' knowledge. This knowledge reconstruction, when integrated with the social metacognitive engagement, was where, as a group, they shared their understandings and thinking (shared metacognitive knowledge) and, based on these understandings, renegotiated their understanding (shared

regulation) (Hacker 1998). The key result was that this comprehensive instructional progression proposed an innovative pathway for incorporating online avenues for deep, meaningful reflection about their thinking and learning while supporting the reconstruction of the teachers' knowledge-of-practice for teaching with technologies – their TPACK-of-practice.

As programs expand to incorporate and take advantage of online learning contexts, teacher educators need to understand how teachers incorporate their thinking about teaching with technologies into their classroom practice – their TPACK-of-practice. The online learning trajectory used in all four of the courses in the Masters program engaged in-service teachers in knowledge-building communities, guiding them in reframing their knowledge for designing student-centered, problem-based learning with the integration of technologies. The culminating course, the blended course, revealed specific benefits of such a blending for a teacher education course. Blending the electronic portfolio tasks (where teachers individually examined their teaching with technologies) with an online community's collaboration and inquiry about instructional strategies resulted in teachers' enhanced thinking about teaching with technologies. Through this experience, the teachers engaged in (1) action research as they taught with technologies, (2) reflective thinking about their teaching with the technologies, and (3) the concurrently used multiple artifacts as objects to think with while reconstructing their knowledge for teaching mathematics with technologies. While this study identified one method for incorporating online learning to guide teachers' reconstruction of their TPACK-of-practice, teacher educators must continue to search for additional ways to guide and support teachers as they are integrating technologies in their instruction, as new and more robust technologies become available for learning tools. The challenge is to incorporate more social metacognitive constructivist features along with online environments to better reflect a more collaborative experience for today's teachers as they continue to build and reconstruct their knowledge for teaching with technologies.

Background

When Seymour Papert first introduced turtle geometry through the programming language Logo in 1967, it was intended to assist children ranging in age from 5 to 17 to learn mathematical concepts through programming and the use of words. Rather than programming using codes that were specific to a particular programming language, Papert simplified this by using common instructions to a turtle – which was first a physical robot (Fig. 1) and then later a virtual one that became an icon on a screen. Commands such as “Right 90” to turn 90° to the right or “FORWARD 20” to advance a specific distance in a straight line were used to make the turtle move. As computers were gradually introduced into schools in the 1980s, students were able to experience using a virtual turtle designed for use with Logo systems through a series of commands.

Papert’s research was rather influential particularly with the use of robots in schools. His constructionist theory emphasized that children learn most

Robotics in Education, Fig. 1 A physical robot – the (Tasmanian) Turtle

effectively when they are playfully engaged in constructing meaningful projects in the world. In 1985 he started collaborating with LEGO to create LEGO bricks that could be programmed to move. Papert’s ideas served as an inspiration for the LEGO Mindstorms kit which was introduced in 1998 and named after his book *Mindstorms: Children, Computers, and Powerful Ideas* (Papert 1980).

LEGO Robotics

In 1995, LEGO DACTA released the Control Lab (Fig. 2) which was designed for educational use and connected bricks to a computer via an interface box that used cables connected to the serial port of a Macintosh or MS-DOS computer. The control box provided a series of input and output ports, allowing it to control motors, lamps, and sound elements, and provided functionality of the temperature, light, touch, and angle sensors.

In 1998, LEGO Education (formerly LEGO DACTA) released Mindstorms, which was the precursor to LEGO Mindstorms NXT in 2006. The kit consisted of a variety of bricks and motors, sensors (ultrasonic, sound, touch, and light), and the NXT Intelligent Brick. The Intelligent Brick is the “brain” and allows the robot to autonomously perform a variety of operations through a programming environment. In 2013, LEGO released

Robotics in Education,

Fig. 2 Picture taken of a student using LEGO Control Lab. (Picture taken 2/5/96)

Robotics in Education,

Fig. 3 The Intelligent Brick – Mindstorms EV3

the third generation of Mindstorms – Mindstorms EV3 allowing the Intelligent Brick (Fig. 3) to upload programs using Bluetooth or Wi-Fi as well as cables.

Mindstorms have been embraced by students globally for its ability to engage across many curriculum learning areas such as Technology, Mathematics, Science, and Digital Technologies (LEGO Education, *FIRST* Australia and QUT 2017). Students are able to work collaboratively and learn through self-directed and hands-on activities.

Robotic Competitions

There are two established organizations that run large international robotics competition: *FIRST* – For

Inspiration and Recognition of Science and Technology – and VEX. *FIRST* has four programs aimed at students in primary and secondary school:

- *FIRST* LEGO League Jr
- *FIRST* LEGO League
- *FIRST* Tech Challenge
- *FIRST* Robotics Competition

VEX has two programs aimed at school-aged children:

- VEX IQ
- VEX EDR

The mission of *FIRST* is to “inspire young people to be science and technology leaders, by

engaging them in exciting mentor-based programs that build science, engineering and technology skills, that inspire innovation, and that foster well-rounded life capabilities including self-confidence, communication, and leadership” (*FIRST* 2018b). Dean Kamen, the founder of *FIRST*, stated that his vision was “To transform our culture by creating a world where science and technology are celebrated and where young people dream of becoming science and technology leaders”(F*IRST* 2018b).

FIRST has a program aimed at younger children (aged 6–9) called the *FIRST* LEGO League Jr. Using a WeDo LEGO kit, children are given a real-world challenge, and they need to use their creativity and programming skills to design a model that moves and responds to the challenge. Students are encouraged to work in teams of up to six students and showcase their work. Unlike the LEGO League, this is more of a celebratory showcase or exposition of the work the students have done.

The *FIRST* LEGO League (*FIRST* 2018a) is an international global challenge aimed at students between the ages of 9–16 using LEGO Mindstorms. The challenge started in 1999, and the inaugural challenge focused around a group of astronauts stranded in a space station. The challenge is changed annually and is a scientific-based real-world problem that teams of students (4–10) need to solve using their design and programming skills using LEGO Mindstorms (Fig. 4). As part of the challenge, there are a number of conditions imposed

such as an 8-week time limit to analyze problem, design, and build the robot to perform autonomously using only four motors.

The *FIRST* Technology Challenge is aimed at students aged 12–17 years to encourage them in using metal and aluminum as base materials to build a robot. Teams design, build, and program their robots. This competition began in 2005 and was originally known as the *FIRST* VEX Challenge.

The *FIRST* Robotics Competition (FRC) is aimed at students aged between 15 and 18 years. A new challenge is issued each year, and students are expected to solve the challenge by building a robot that will assist to solve it. The FRC robots are designed and built in 6 weeks (from a common set of parts) by a team of senior secondary school students and a small group of dedicated industry-based engineers, computer programmers, and university undergraduates, who become the team’s mentors (Fig. 5). There are a limited number of resources that the students can use when they build their industrial robot that weighs approximately 50–60 kg. There are no limits to how big teams can be, and students build, program, and remotely control a robot of their own design. They learn to use software and hardware by working alongside professional experts.

VEX Robotics Competition is formerly associated with *FIRST*. There are two divisions of this robotics competition aimed at different age groups. VEX IQ is aimed at primary and early secondary students, and VEX EDR is for

Robotics in Education,
Fig. 4 *FIRST* LEGO
League held in Melbourne
2015

Robotics in Education,

Fig. 5 Melbourne RoboCats #5648 picture with the robot they built for the FRC

secondary school students. A yearly challenge is issued, and students design, build, program, and drive a robot to complete the challenge. In the VEX IQ Challenge, students are expected to construct a robot using the VEX IQ Robotics set by putting together plastic pieces. The sizes of the robots are similar to the *FIRST* Technology Challenge, and they use similar types of metal. The students then use software to program the robot.

Robots in the Classroom

Robots have been used in education for over 20 years; however, their inclusion into the curriculum has only normalized over recent years. Robotics are increasingly being used by younger children through technology friendly tools that encourage students to engage with them. Bee-bots (Fig. 6), for example, are a small yellow and black robot that is encased in a friendly bee design. This design is used to entice students to interact with the robot by allowing students to sequentially program the directional buttons back, forward, left, and right. Students can place up to 40 commands that allow the Bee-bot to move.

As younger children do not have adequate reading abilities, programming through color coding is another method to engage students with programming and robotics. Ozobots (Fig. 7) are

Robotics in Education, Fig. 6 Bee-Bot moving along a mat

a small robot that detects sequences of colors and performs different actions when it reads the colors. The robots can interpret approximately 25 code commands which control the speed, direction, and timers of the robots. Young students only require four markers (black, red, green, and blue) to draw the sequence that they want the Ozobot to follow along a maze. Students are

Robotics in Education,
Fig. 7 Ozobot following a
 color-coded maze

Robotics in Education,
Fig. 8 A Pro-Bot moving
 autonomously on a mat

able to control the robot by using a sequence of steps or commands through color coding.

Pro-Bots use the LOGO programming language. Pro-Bot commands are entered via a set of arrow and number keys affixed on the back of the car. The Pro-Bot will follow the sequence of commands that were entered step by step autonomously. The Pro-Bot (Fig. 8) is similar to the interpretation of the turtle; however, in this case it is shaped as a yellow car. Pro-Bots are suitable for children between 9 and 12 years of age.

Other robots that are also being used in the classroom include Sphero (Fig. 9), which is round, clear, or opaque, with a multitude of lights that change colors. The Sphero is approximately the size of a tennis ball. The robot's ability is to roll around and move in different directions

controlled by a smartphone or a tablet via Bluetooth. Although, they have been used in education with students, these devices are also seen by some to be a toy.

Other robots that are considered to be a cross between a toy and an educational robot are PLEOs (Fig. 10) which is an animatronic pet dinosaur with several body parts that move such as eyelids, legs, and its long neck. The robot uses a variety of sensors to recognize colors and patterns, listen to sounds, and react to temperature. When the robot is initially unboxed, it behaves like a newborn hatchling and needs to be raised to be mature to activate all its features. While this robot has the ability to be programmed, it is used more as a tool to demonstrate functionality of robotics and sensors.

Robotics in Education, Fig. 9 Sphero

Robotics in Education, Fig. 10 PLEO the dinosaur

**Robotics in Education,
Fig. 11** NAO humanoid
robots developed by
SoftBank

Humanoid Robots in the Classroom

Humanoid robots such as the NAO robot have been trialed in schools in South Australia across early childhood settings and primary and secondary schools (Keane et al. 2016). These robots are preassembled and take the shape of a human form with two arms, two legs, a body, and a head. Standing at 58 cm tall, it has 25 degrees of freedom to allow movement of all of these parts. The robot senses and its moves emulate human interactions, such as sight, sound, touch, and social behaviors which can be programmed through drag and drop software or through Python code. The robots look like a child and are friendly looking, encouraging students to befriend them. While these robots show promise to be used in the educational context, the cost of each individual unit is prohibitive (Fig. 11).

From the research in South Australian schools, it was found that the technology engaged students in their learning and promoted curiosity, challenge, critical thinking, creativity, collaboration, and communication. It was found that curiosity and challenge fostered critical thinking, creativity, collaboration, and communication and that enabled the development of high-level skills in computational thinking and coding.

Robotics in Education, Fig. 12 A JD robot from EZ Robot

As robotics have moved into the mainstream, and no longer considered to be the domain of a select few, students are increasingly provided with opportunities to program and work with these tools. There are many educational robots that are being developed and used in schools each with a slightly different variant. For example, the LEGO robots require students to not only use their creativity skills to design and build their robot but to also program them. A Bee-Bot requires some programming to do a limited number of movements. A NAO humanoid robot requires programming to engage the motors, sensors, and outputs. Other variants of robots include the JD robot (Fig. 12), where the students build the robot so that it looks like the packaging. The JD robot is a Wi-Fi-enabled humanoid robot that has 16 degrees of freedom powered by gears and motors that are supplied. In addition to the ability to build and program this robot, the JD robot allows for parts to be 3D printed.

In Summary

When Papert was first advocating the benefits of robotics and programming through the constructionism theory, robotics in education was not very popular among students and schools. In recent times, robotics has become prevalent in schools and classrooms in conjunction with the elevated recognition of STEM (Science, Technology, Engineering, and Maths) subjects. Robotics has become accepted in the classroom as teachers and their students engage with this technology and the programming element of it. With already established international competitions, schools are looking into innovative methods to engage their students with technology. There is a consensus that robotics in education is valuable (Bredenfeld et al. 2010); however, the lack of empirical evidence to prove whether there is an impact in early childhood settings and primary and secondary school education still remains (Williams et al. 2007).

Introduction

This paper describes the requirements for a safe frame in teaching with and researching on educational technologies among an Indigenous community in Northern Manitoba, Canada. Following abuse and misuse of access privileges by researchers, policies were created for conducting research in Indigenous communities that are protective of Indigenous research communities and their members. As a result, all researchers including outsider researchers who intend to conduct research in these contexts must comply with these established policies and

protocols. Despite these frameworks, the success of a research is not guaranteed.

The concern for entry into an Indigenous community for the purposes of conducting a research emerged during my doctoral studies which was based on a study that examined how Indigenous adult postsecondary learners in this remote Canadian Indigenous community would adapt and orient themselves between Eurocentric and Indigenous cultural ways of learning. The study utilized digital technology such as mobile phones in producing documentation for adaptive and orienting between these ways of learning.

The study was conducted in a rural Indigenous community that was situated over 940 kms north of the closest large urban city. With a population of about 2000 inhabitants, one elementary school, a high school, and a distance education learning center, this community is geographically far removed from the reach of urban education. Educators who facilitate learning have to periodically travel by air to do so or go via ice roads during the winter seasons.

Thus, digital technologies, such as video- and conferencing, present an interesting alternative to accessing learning materials for learners in this community. With the recent implementation of a third-generation mobile network, learners were presented with another interesting opportunity to leverage mobile devices to either access content, engage in collaborative learning, or even participate in further research.

Despite these alternatives, the larger question concerned the state of pedagogical preparedness of instructors, the level of administrative readiness of educational institutions, and the positionality of learners to utilize these technological advancements as tools that could enhance student learning in the research community.

Much of these concerns were examined in the thesis (Akoh 2016a), in which a framework was produced to (a) guide policy makers, government agencies, school administrators, educators, and students to better collaborate for negotiated learning and adaptations, (b) trigger recognition of the importance of these movements as an essential learning element in indigenous communities, and (c) cause an exploration of the more intrinsic functions of Internet technologies, specifically mobile technology, to facilitate learning negotiations.

This paper however addresses an aspect of the larger study related to the need for constructing a safe frame for research participants who were also students in the distance education learning center. Parallels could be drawn between the research and teaching as the study activities were learning based.

As a non-Indigenous Canadian researcher, conducting a technology-based research in an Indigenous context, there were strong issues of access, even more so, in a policy-protected research context. The policies required researchers to abide by protocols and ethical practices that protect the research community, the people, and Indigenous knowledge from exploitation and “predators and biopiracy” (Battiste 2005). Exploitative research practices had left a bad taste in the mouths of Indigenous communities. This paper is based on a conceptual safe frame (Miller 2001) that was used during the study. It is presented here to elaborate on the need for a safe frame as an essential requirement for conducting research and for teaching in contexts where access may be limited, where differences of cultural backgrounds exists, and where technology is used as a tool for learning. The paper has six sections.

In section “[Contextual Background](#),” the contextual background of the study is described to

present the reader with the physical challenges involved in conducting a technology-based research in a rural community where Internet and mobile access is minimal. This section also describes the policy framework required for researchers to conduct studies in these communities. In section “[Insider/Outsider Research Dilemma](#),” the dilemma of conducting a research as an outsider is presented. This complexity requires the researcher to provide higher levels of assurances, beyond adherence to the policy frameworks such as the need to construct a safe frame. This is discussed in section “[Safe Frames](#)”. Section “[Safe Frames as an Essential Determinant](#)” describes the constituents of a safe frame in research community.

Contextual Background

Canadian Indigenous population is known as Aboriginal. Aboriginal population consists of First Nations, Inuit, and Metis peoples who represent about 4% of the Canadian population as at the 2011 census. First Nations people represent 2.6% of the Aboriginal population, Metis represent 1.4%, and Inuit represent 0.2%. Together, they consist of 1.4 million people identified with an Aboriginal identity (StatisticsCanada 2011). Fourteen percent of this population resides in Manitoba where this research was conducted.

Although the numbers are improving, Aboriginal people aged from 25 to 64 with a postsecondary qualification are at 48.4% compared to 64.7% of non-Aboriginal students with a postsecondary credential in 2011, up by nearly 6% in 5 years. About 14.4% have a trades certificate (cf. 12% of non-Aboriginal), 20.6% with a college diploma (cf. 21.3% of non-Aboriginal), 3.5% with a university certificate below a bachelor level (cf. 4.9% of non-Aboriginal), and 9.8% with a university degree (cf. 26.5% of non-Aboriginal) (STATSCAN 2016). Aboriginal students represent about 3 to 4% of the undergraduate student population in Canadian universities and colleges (TRC 2015; AUCC 2011). Only “8.7% of First Nations people, 5.1% of Inuit and

11.7% of Metis have a university degree, according to the 2011 census” (TRC 2015).

Younger Aboriginal people in the 35–44 age bracket have proportionally higher levels of education at 68% than their counterparts in the 55–64 age bracket at 58.7% with a high school diploma. Younger Aboriginal women have 13.6% compared with 10.2% of their older counterparts with a university degree.

Despite these improving numbers, attrition rates are high and continue to plague Indigenous education (Demmert 2001; Raham 2009; Kirkness 1999; Akoh 2016b). Improving education numbers is one of the many areas of research involving Indigenous peoples. Health, social structures, economic development, and learning technologies (Mignone et al. 2011) are some of the other areas of research. Researchers in these areas perceptively intend to contribute research that benefits Indigenous communities and their people, even though Indigenous people feel they “have been researched to death” (Schnarch 2004).

Private, public, academic, and individual research have been conducted in Indigenous communities, with researchers treating community people as “merely a source of data,” implementing research programs without community knowledge or even consulting with them to determine “what kinds of projects might serve their needs” or to treat Indigenous peoples as partners in the research (Schnarch 2004). In some cases, researchers have used collected information against them.

Consequently, ethical protocols and principles have been developed to protect research integrity in Indigenous communities. One of such protocols and principles is the *Ownership, Control, Access and Possession* (OCAP) (OCAP/FNIGC 2013) protocol which guides research “monitoring and surveillance, surveys, statistics, cultural knowledge, and so on” (Schnarch 2004). The protocol essentially grants ownership of all information collected during the research to the community involved; the community can control how the information is used, can manage the information and make decisions about its use, and can assert ownership on the information collected during the research. Although OCAP was

meant for the health sector, its reach spread broadly to all forms of research.

In addition to OCAP, the *Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans* and the *Integrated Knowledge Translation* framework ensure that researchers leave research knowledge behind for the benefit of the research community (GC 2014; CIHR 2011). These frameworks are among the many other ethical guidelines researchers are required to meet. In addition to these frameworks, universities set up ethics committees who prescribe institutional guidelines and grant ethics approval for research on human participants. For instance, the study from which this paper emerged was granted ethics approval by two universities, the University of Manitoba, Education Nursing Research Ethics Board (ENREB), and the University College of the North research Ethics Board (UCN-REB). Both universities had to grant research ethics because the former is the degree-granting institution and the latter is the host institution responsible for delivering learning to the research community.

These formal structures were necessary for access to the research community, and they provided the ethical core necessary for conducting research that involved Indigenous participants and their communities. Similarly, additional community-based protocols that involve acquiring the permissions and consent of the Chief and Council, a local governing board involving elders of the community, have to grant access to the researcher prior to the commencement of research.

But compliance to these formal structures alone is insufficient for successful research, and does not guarantee research participation by participants. For instance, the overarching study from which this paper is based utilizes purposeful sampling as a recruitment approach for research participants (Suri 2011; Patton 1990; Coyne 1997). Purposeful sampling allows the researcher to sample and select “information rich cases for in depth” study. Other important elements that guarantee the safety of, and instill confidence in, the research participants are required in order to secure active participation. Collectively, these

formal structures such as the policy frameworks, community-based protocols, and the confidence of research participants are required to create a safe frame that is essential for successful research and, by extension, teaching, in Indigenous communities.

Another layer of complexity concerns my role as a non-Indigenous Canadian with an Indigenous African/Nigerian background, often described in ethnographic research as insider-outsider dilemma (Merriam et al. 2010; Dwyer 2009; Kersen 2016). This role is significant to the construct of a safe frame.

Insider/Outsider Research Dilemma

Researchers who share the same identity, language, and experiential base with their study participants are called insider researchers (Dwyer 2009). Their position improves legitimacy, increases acceptance, enhances open communications between participants, and engenders trusts between researcher and participants. A significant benefit for insider over outsider researchers is access, preexistent entry, and common ground to the research community. The insider researcher has a “starting point (the commonality) that affords access into groups that might otherwise be closed to outsiders” (Dwyer 2009).

Most ethnographic researchers experience insider-outsider dilemma during research (Merriam et al. 2010; Thomas et al. 2000). Even studies that are systematically designed using an insider-outsider approach are confronted with challenges including the potential fragility of the research team, the need to constantly maintain relationship with the research participants, and the need to completely adhere to ethics, confidentiality, and privacy of the research participants (Thomas et al. 2000).

I approached this study as a Canadian of African descent disadvantaged as a non-Indigenous researcher and who was an outsider to the research context. The definition of indigenous people remains variable because “only indigenous peoples could define indigenous peoples” (Cornthassel 2003). For context, however, it

is used here to represent persons and communities situated on a land and within a local context such as the Aboriginal people of Canada or a Canadian of Indigenous origins from the Idoma people of Nigeria from where I originate and with which I self-identify. Yet, as an indigenous African/Nigerian in Canada, I do not qualify as an Indigenous Canadian of Aboriginal descent.

Nonetheless, my research interests concern Indigenous people broadly and Aboriginal people specifically. Thus, the struggle for ownership, identity, and relevance of my research becomes important, as well as the ownership, control, access, and possession of the research data. One important struggle relates to whether my identity as a non-Indigenous Canadian can conduct or situate self within the peripheries of Indigenous research. Although I self-identified as Indigenous based on my African/Nigerian origins, there remained a fundamental difference between my Indigenous African roots and that of my Canadian research community. Further, the aforementioned perceptions of researchers by Indigenous communities were never in my favor, to begin with.

Despite the differences, there are commonalities I shared with my research context that benefited the research outcome. While I understood the insider’s direct relationship with the research context, outsiders seemed to provide useful and corroborative experiences and perceptions that benefited the research context and participants (Dwyer 2009; Thomas et al. 2000; Damianakis and Woodford 2012). The boundary between the insider and the outsider, though large, directly or indirectly seemed to affect them both, as outsiders provided perceptions from the outside that benefited insiders. For the outsider, it is a conflict of positions that mostly questions the authority he/she has to conduct the research, to whom the intellectual property of the research belongs, or the ethical grounds by which the outsider must stand on to express an insider phenomenon (Damianakis and Woodford 2012).

The insider-outsider context provided further complexity to the study and, even more so, necessitated the need for constructing a safe frame.

Safe Frames

The concept of safe frames emerges from social and health work (Miller 2001; Campling 2001). They have their histories in “therapeutic communities” described as “small cohesive communities where patients have a significant involvement in decision-making and the practicalities of running the unit” related to their wellbeing (Campling 2001). It is the responsibility of the staff in these units to provide a safe frame for patients’ involvement in the treatment process. Safe frames engender a culture of enquiry and shared ownership of understanding, and not perceived to be the sole prerogative of the social worker.

Constructed safe frames allow patients to increase confidence in the health worker such that they are willing to “express distress or ask for help in a constructive manner” (Campling 2001). Within the context of a therapeutic community, Campling describes the need for a safe frame, especially for patients that could potentially act in a destructive manner, as follows:

The task is to provide a safe frame within which they can explore intrapsychic and interpersonal problems and find more constructive ways of dealing with distress...The structure of a therapeutic community, with its community meetings, diverse network of relationships, supportive peer group, strong sense of belonging, 24-hour support, structured day and clear rules and boundaries owned by the residents, means that a strong therapeutic attachment can be forged – an attachment that can withstand high levels of aggression and risk. (Campling 2001)

This concept of safe frames is not too distant from Miller’s, who draws similarities to health practices and teaching by advocating for a safe frame for learners involved in trauma studies (Miller 2001). Miller warns that instructors who teach students who are learning about trauma should be aware that exposure to content, literature, and trauma cases could have far-reaching consequences on students’ inner experiences. Some students may have been “exposed to traumas or losses in their adult lives, including domestic violence sudden death within one’s family, serious illness, or other workplace trauma, further compounding the impact of studying

about trauma and treatment (Miller 2001). Miller suggests that teachers should become more attuned to their own, and consequently, their students’ reaction to learning materials. Further, teachers should “differentiate the classroom experience from the therapeutic personal experience” (Miller 2001) and introduce journal writing to allow students express their responses to trauma exposure. Miller describes a learning safe frame as a safe environment that is available:

both for the individual student, and for the collective classroom experience...It is the instructor’s presentation of educational focus, tone, boundaries, and frame for the class that can define the parameters of the class discussion and shared expression...Learning in the context of trauma also is deepened when a climate of safety is provided. Because the intensity of this learning and experiencing environment affords deep awareness, and also replicates the original fields of interaction, attention to safety is further required. (Miller 2001)

Participants in the study captured in this paper have historically been known to experience trauma and have engaged in self-harm practices. For instance, suicide rates among Canadian Indigenous learners continue to increase, requiring that the government engage more actively to mitigate its impact on the future of young Indigenous peoples (TRC 2015; Toulouse 2013; Dunlop 2016; Eggertson 2015; The Government of Canada 2016). Further research may be required to draw correlation between the increasing use of digital technology and the growth in suicide and self-inflicted injury numbers among members of this community. However, there was evidence of cyberbullying in the research community as community members became more conversant with the use of digital technologies. The impact of this on learning and research is discussed further below.

Safe Frames as an Essential Determinant

The study examined how Indigenous adult post-secondary learners who are located in a remote community in Northern Manitoba, far from the reach of urban education, were able to negotiate their learning by adapting and orienting

themselves between Eurocentric and Indigenous learning methods. Using digital technology such as mobile phones, participants produced documentation about these adaptations and orienteering. The aim of the study was to identify the determinants of these negotiated learning and adaptation. A useful application of the outcomes of the research is its contribution to knowledge and its potential for addressing Indigenous education challenges such as high attrition and low participation rates among Indigenous learners.

The research methodology was phenomenology, allowing participants to provide more in-depth and contextual data about their negotiated learning and adaptation (Creswell 2006). Through narrative inquiry, participants responded to questions about their lived experiences (Clandinin and Connelly 2000).

A total of 14 participants were recruited into two participant groups: eight (8) primary research participants were directly involved in research activities, and six (6) secondary participants were interviewed only to provide contextual information to the study. Participants were identified using purposeful sampling (Suri 2011; Coyne 1997), which allowed for sampling and selection of “information-rich purposeful cases for study in depth” (Patton 1990).

Participants utilized their personal mobile devices including iPhone, iPods, smartphones, iPads, etc. and the apps on them such as camera, voice recorder, and video recorder to capture video, voice, and data of the interviews they conducted of their family, community, community members, and themselves. Participants interviewed family members on culture-centric questions related to their cultural histories and traditions, such as original birthplace, family history, level and type of Indigenous education received, housing structures, transportation, parenting styles, traditional medicines and ceremonies, and strategies for survival.

Upon gathering this information, participants analyzed the responses and then produced individual reflections of their own learning practices, which they recorded as video and voice and on blog posts or notebooks. They were consequently interviewed, using the overarching research

question, “what are the determinants of technological adaptive orienteering among adult learners in your community?” Their responses provided the primary data for the research.

Upon analyzing the data, various themes and sub-themes emerged and were categorized. One emergent thematic area concerned the impact of digital technology on the local culture such as its role in enhancing existing traditional practices and in erasing, preserving, or making it obsolete (McLuhan and McLuhan 1988). Some participants felt that digital technology had increased vulnerability and created exposure to cyberbullying. This outcome highlighted the need for the construction of a safe frame during classroom learning. The constructed frame had four levels (see Fig. 1).

In describing the contextual background of this paper, I described the research policies that had been put in place to guide research in Indigenous communities. These policies such as the *Ownership, Control, Access and Possession* (OCAP) (OCAP/FNIGC 2013), the *Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans*, and the *Integrated Knowledge Translation* framework (GC 2014; CIHR 2011) are frameworks defined by government departments to protect Indigenous communities from unscrupulous researchers. These policies are also applicable for teaching. They are the first-level components of the safe frame.

Safe Frames, Essential Determinant for Educational Technology Implementation in an Indigenous Context, Fig. 1 Safe frame

The second-level components are the institutional ethical frameworks, which provided students, researchers, and educators with the boundaries for their work and prevented them from undertaking activities that could negatively impact human participants. It also allowed participants to become familiar with the extent of their involvement in the process. Participants have the option to opt out and can withdraw their complete participation in the process.

The third level of this safe frame concerned the culture-centric responsibilities of the researcher to the research community. This level required the “blessing” of the elders in the community. The research design was presented to the Council of Elders, to offer suggestions and to grant permission prior to conducting research activities.

Even with the blessing of the Council of Elders, participation in the study is not guaranteed, resulting in the construction of a fourth level of this safe frame. Participants may be present but may not affectively engage in the research. This form of participation will not produce the level of depth nor generate the quality of data required. Because cultural practices were nuanced to the research community, they cannot be generalized. Relationships were established directly with the community members to construct this level of the frame. This involved constant visit to the research community, building relationships with research participants, engaging with the local Elders and Council of the community, and presenting the research in a transparent manner to them. Parts of this frame involve making full disclosure about the research, proceeding cautiously by ensuring that the availability of researchers are respected, respecting the time constraints of the participants while adjusting activities to fit their schedule, and ensuring that the research outcome involved “giving back” by adhering to the promise to leave research knowledge with the community upon completion (Akoh 2016b).

Discussion

The components of the frame described earlier had to be developed by and for the research

community. Successful research could not be conducted solely upon promises to abide by ethical principles. Carefully constructed respectful relationships with the research community and potential research participants were essential. The notion of developing relationships with the research community prior to commencement of the research would have been in direct conflict with the requirements of existing ethical frameworks, which prevented researchers from making contact with the research community prior to the commencement of research activities. A safe frame will not contain this component, and could be even more stringent for outsider researchers seeking to conduct a study in an indigenous context, thus making the frame fragile.

It was necessary to develop confidence in the research participants. To do so, engagement with the research community took over 2 years to develop, involving regular travels to community, presenting papers and research ideas with the Elders and Council, and at conferences hosted in the community, and even living in the community while conducting the research.

Participants had to feel safe by constructing a requirement for confidence in the safe frame. This level of confidence was tested when participants’ personal traumatic experiences surfaced resulting in their unavailability to participate and unwillingness to communicate about their traumatic experience. The constructed safe frame was fragile requiring a more affective and self-conscious approach to the research activities, described as a personal code of ethics and captured in this self-reflection:

A personal sense of ethics derived from a feeling of having experienced trauma of the other. We cannot be empathetic towards another if we ourselves are not in the position of the other. . . we have a personal sense of ethics towards the other; we would not impose our ways and times of doing things on them. Rather, we will concede that they have their challenges and from this, we find ways of adapting to their learning using their time. We cannot impose our time on them (personal reflection).

The self-consciousness, to be cognizant of this safe frame, may be unrequired for an insider researcher, but it is of prime importance to an outsider researcher, more so in the context of

technology use. Outcomes from the research indicated that the use of social media on mobile devices resulted in creation and transmission of inciting messages that heightened the trauma of community members. Cases of cyberbullying increased as community members made social media posts with little consideration to the feelings and emotions of their target recipient.

Arguably, the boundaries of the safe frame dissolved when community members used digital technologies and social media for interaction between themselves but erected them when outsider participants/researchers were involved. It would appear that a safe frame was not required when community members interacted with each other; the frame tended to dissolve under the illusion that the sender and receiver of messages did not need it.

Three important conditions were required in the construction of this safe frame, (a) a feeling of safety, (b) assurances of privacy, and (c) guarantees of equity.

(a) *Safety*

Participants were critical of the digital technology used in the study. They expressed wishes of safety concerning the use of digital technology, even though they had owned and used them prior to the research. One participant expressed the need for this feeling by requesting that the outcomes of the research benefit the community, that the application of digital technology in this context was done in a safe way without harm to the community members, and that community members, including elders, parents, and teachers, are constantly consulted throughout the research. Remembering the potential for cyberbullying and self-harm, participants recalled the need for much safer and happier times of the past, prior to era of digital technology when community members live in peace and there were not many incidences of traumatic experiences.

(b) *Privacy*

A second condition for this frame included assurances of privacy. Participants expressed the need for privacy by suggesting

that privacy exceeded merely keeping communications within the boundaries of the safe frame. Participants wanted to be assured that data loss would not occur and personal information would not fall in the wrong hands. Participants had to develop their own levels of confidence and assurances in the use of the digital technology as they were informed of the privacy requirements of each digital tool and the extent to which violating privacy rules could lead to loss of data or misuse.

(c) *Equity*

A third important condition is the need for equitable relationship between participants, researchers, and potentially their instructors. Even though participants were aware of the power relations present between them and outsider researchers and instructors, a safe frame would be destroyed if they felt their culture was being undermined, especially in the light of ongoing perceptions about “cultural genocide” that undermined their culture in relation to Eurocentric culture (Battiste 2004, 2005; TRC 2015).

These conditions were necessary within the safe frame. Through the construction of a safe frame that encompasses these policies, community protocols, and conditions, successful access to the research community was attained. However, it was the outcome of the research, such that it benefited the research participants and their community that was strongly highlighted.

Conclusion

The notion of safe frames is described in this text so that future researchers and teachers in Indigenous communities, who use technology, may be able to produce research and learning outcomes that seek to benefit community members and the context in which their research is performed. The objective is to address challenges with Indigenous learners where there may be a need to scaffold their learning from a cultural based with which they are more familiar

to a less familiar base such as an Eurocentric learning worldview. Digital technology, such as mobile devices, appropriated within Indigenous context and utilized in a culture-centric manner, and in compliance with a constructed safe frame, holds promise in addressing some of the challenges of adult learners in Indigenous communities.

This paper describes aspects of a larger study in which digital technology was used as a tool documentation of adaptive and orienteering movements from Indigenous ways of learning to Eurocentric ones undertaken by adult learners in a Northern Indigenous community in rural Manitoba. The research was conducted by a non-Indigenous Canadian in an Indigenous setting, which provided some levels of entry complexity to the researcher. In compliance with the various policies and protocols in place, access to conduct research in this community was not sufficient, hence the need to construct a safe frame that assured research participants of the levels of confidence they needed to actively engage in the study.

This study does not intend to generalize this aspect of its findings as a rigid structure of safe frames. In fact, safe frames are nuanced to the communities in which the research or teaching is delivered. It is the responsibility of the researcher or educator to develop the most appropriate frame consisting of the elements that could address the needs of their specific community. Thus, more nuanced research is required.

The research presented in this paper, however, highlights three important aspects: (a) that safe frames are a required construction in research context where trauma and self-inflicted harm are prevalent; (b) that digital technologies, especially mobile devices, could play a significant role in understanding the cultural nuances in the research community and are necessary for highlighting the pedagogical applications of digital technology; and, finally, (c) that constructed safe frames may be the missing piece in understanding and addressing learning problems that are evidenced by symptoms such as high attrition and low completion rates among adult learners in Indigenous learning context.

Introduction

Computers were being used in management applications in some Victorian schools long before the Department of Education got involved in providing administrative software for schools in the mid-1980s. Some schools, in which a particular teacher had an interest in computing, used teacher-designed BASIC programs on Apple// computers for things like scheduling and recording information about the school sports, for word processing in the school office, for assistance with timetabling, and for listings of students in each class. These were very much single school applications (Tatnall 1995).

Every school needs to store large quantities of administrative data relating to matters concerning individual students, groups of students, parents, teachers, events, and curriculum. This entry reports on how one primary school in the Australian state of Victoria makes use of its educational management systems.

Australia is a federation of six states and two territories. The Commonwealth Government is based in Canberra, but school education is the province of the state governments. Government schools in Victoria enroll only about 68% of Victorian students, the remainder being catered for by the independent and Catholic schools (Victoria State Government 2018). This entry deals only with management systems in Government schools.

Hurstbridge Primary School

Hurstbridge Primary School is situated in the semirural town of Hurstbridge 32 kms northeast of Melbourne. The picturesque setting of the school, newly constructed in 2005, is set among the gum trees along the Diamond Creek and provides a magnificent environment for members of the school's community. The school comprises two main wings, a library and computer lab, art room, music room, instrumental music rooms, aftercare room, hall, and science and Italian room (Tatnall and Tatnall 2014, 2007; Hurstbridge Primary School 2018).

In 2018 the staffing profile consists of a principal and assistant principal and ten classroom teachers and specialist teachers. Chris Tatnall is the school principal.

Administrative Systems in Victorian Schools and Their Use at Hurstbridge Primary School

There are two categories of application software used in Victorian schools: curriculum applications and administrative applications. To keep these separate, schools have two entirely separated and unconnected networks:

- A Curriculum Network that is accessible by teachers. This can be accessed throughout the school using either Ethernet or Wi-Fi connections.
- An Administration Network that is accessible only to school management and school

administrative office staff, but not to teachers. The Administrative Network is accessible only via an Ethernet connection at specific locations.

CASES21

In the early 1980s, a newly elected Victorian Government found that it was not possible for it to get consistent financial data from all its governments departments, as each had its own accounting system (Birse 1994). This meant that the government was unable to draw up a balance sheet for the State of Victoria as a whole and as a consequence it quickly decided to set up accounting standards that would be used by all government departments and to institute a centralized accounting system (Tatnall 1995). In the case of the Department of Education, with the aim of making schools more centrally accountable, this system *imposed* an unalterable chart of accounts, which for small primary schools was seen as unnecessarily complex. Birse (1994) suggests that “the system was definitely not set up to empower schools. It was fairly imposed, and from that point of view they got it wrong.” The result was CAAS (Schools’ Administrative Systems Development Unit 1987) where the development philosophy placed emphasis on an integrated database management system: “All school records should be part of an overall construct where a general information system comprising students, staff, assets, facilities and financial data is readily available to school-based personnel to assist in the

administrative process” (Directorate of School Education 1993). CAAS was designed to be used with MS-DOS and a later version became known as CASES. Since that time CASES has been through several different versions culminating in CASES21 which, in 2018, is used in all Government schools in the state (Fig. 1).

The Computerised Administrative System Environment in Schools (CASES21) (CASES21 is a customized version of the Maze school software system, marketed commercially by CIVICA.) provides support to Government schools for administration, finance, and central reporting (reporting back to the Department of Education). CASES21 runs on a Windows PC within the school and is claimed to have been designed to be easily modified to meet evolving school business needs. It currently has two main modules:

- **Administration module:** student and family records, photos, enrolments and census, student medical records, welfare, accidents and sick bay, attendance, student achievement, incidents, discipline and merit, activities, excursions, home groups and houses, staff records and photos, daily organization and calendar, timetabling, school details, management, and council and parents’ clubs.
- **Finance module:** payroll; staff records and leave for school-level employees; student, family and sundry debtors; creditors; asset

School Management Software in a Primary School in Victoria, Use of, Fig. 1 CASES21 (a customised version of the Maze school software system)

register; budgets; reporting; and end-of-year and end-of-financial year (Department of Education and Early Childhood Development 2011a).

The use of CASES21 is mandatory for all Government schools, and all school data is stored on-site but automatically backed up online remotely by the Department of Education. This means that the Department of Education can create its own reports from any of the school’s data and the school doesn’t need to send it anything. Within the school, CASES21 is used by school management and office staff with no direct teacher access. CASES21 is linked to most other management systems within the school and to the Department of Education.

Apart from assisting schools with some administrative tasks, perhaps the biggest difference made by the introduction of CASES21 was the flow of information back to “Spring Street” – the location of the Department of Education (Its location is Treasury Place, Spring Street.). It is now very easy for someone in Spring Street to obtain details of the finances, enrolments, teachers, students, and maintenance requests for any school in the state.

Financial matters are now handled by office staff in the school, but the Department of Education has online access to all this data at any time. Use of CASES21 makes the task of handling finance, record keeping, and enrolments by the school very much easier.

School Maintenance System (SMS)

Audits of all (Government) schools are carried out each financial year by the Department of Education to determine the maintenance needs of each of their buildings. Based on priority considerations, it then determines works to be included in its maintenance program, and the prioritized data is loaded onto the School Maintenance System (SMS) in order to assist with its statewide maintenance and infrastructure planning (Department of Education and Early Childhood Development 2013). SMS is accessed online and linked to CASES21 (Fig. 2).

At the school level, SMS is used to assist with buildings and facilities, property management, repairs, and urgent works. At Hurstbridge Primary School, it is used mainly by the assistant principal and the school office staff. As SMS works online, the Department of Education is always easily able to see the school’s spending patterns and to check to see that the cost of all maintenance, repairs, and urgent works is within the school’s global budget. An important feature of SMS is for tracking urgent works, which is done automatically.

Before introduction of this fairly new system, purchase orders to a contractor for any school maintenance tasks had to be handwritten at the school and then sent off to CASES21 for Department of Education approval. Now, after the school has set up the system with contractor names and other details, when maintenance is needed, it sends an order to the contractor and also enters

School Management Software in a Primary School in Victoria, Use of, Fig. 2 School Maintenance System (Department of Education and Early Childhood Development 2018c)

this directly into CASES21 where all the data is stored remotely. The school office staff then just pay the bills from CASES21, making it easy for the school to track spending.

This system is also used for routine inspections and occupational health and safety issues. Once set up, the system remembers dates for checking and ordering of these inspections. Use of this system has made these school administrative tasks a good deal easier.

EduPay

While selection and appointment of teaching and administrative staff is done at a school level, the Department of Education manages the payment of all salaries. The Department's HR and payroll system – EduPay – is web-based and designed to enable viewing of up-to-date leave and salary information. It also allows school teaching and administrative staff to access their payslips, to apply for leave, and to view and update their contact and banking details (Department of Education and Early Childhood Development 2018a). It also is linked to CASES21.

Recruitment and position advertisements are done via the EduPay website. Schools list their new teaching jobs and openings over the weeks on the EduPay website, and then this is transferred to the Department of Education "Recruitment online" website. Using this system is the only way in which teachers can apply for new positions. The way that this is done is that the teacher writes a job application, taking care to take note of the selection criteria, and then uploads this as a PDF onto the recruitment online website. Recruitment online then automatically sends emails to prospective applicants to tell them whether they have been shortlisted, not shortlisted, or successful. If they are successful, then EduPay sends out their employment contract.

EduPay is also used by staff in schools to track their performance. Each staff member, teaching and nonteaching, is required to enter a Performance and Development Plan (PDP) each year. This plan sets out what the staff member is hoping to achieve during a 12-month period. The principal will use EduPay to approve and sign off on each staff member's plans. The

principal also makes comments on the plans during the staff member's reviews each year. This plan is linked to the principal's PDP and also the school's strategic plan (Fig. 3).

For quite some time, teachers have been paid by direct bank transfer rather than by check. Before the EduPay system, teachers were sent payslips each fortnight with information about this pay, leave, etc. All this information is now provided online. Whether this is better is a matter of personal opinion: some teachers are happy with this, while others would prefer a printed payslip rather than having to go online to check.

Program for Students with Disabilities (PSDMS)

PSDMS has been designed for use by schools to provide information about support processes associated with funding applications, eligibility evaluations, and budget reporting for students with physical and intellectual disabilities. This program provides funds for teacher aids to assist these students, and not for facilities or equipment. PSDMS also is linked to CASES21 (Fig. 4).

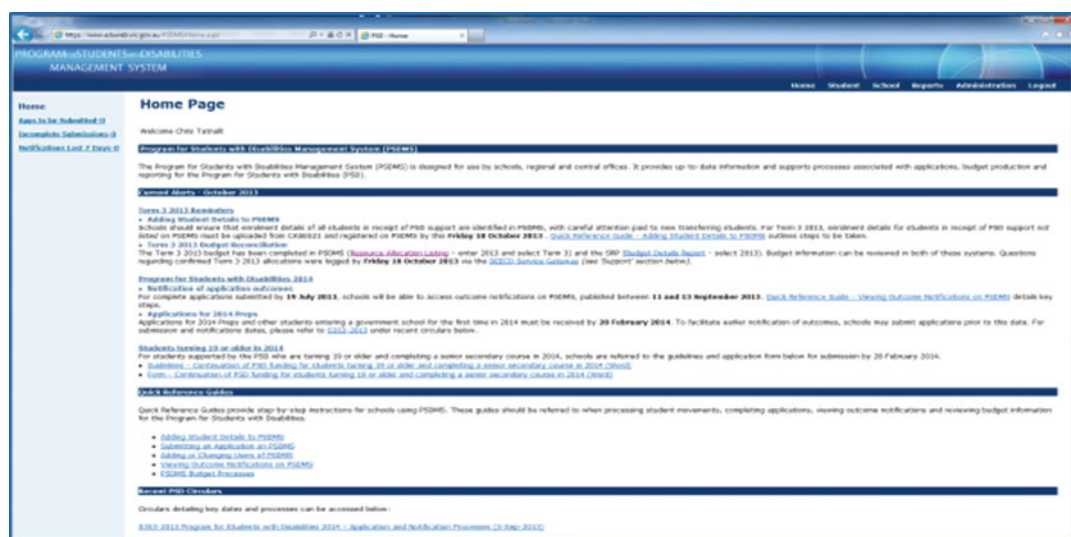

The school has found that the system's provision of information about support processes associated with funding applications, eligibility evaluations, and budget reporting for students with physical and intellectual disabilities is a big improvement on doing this by hand.

Ultraset

The Ultraset (now discontinued) was designed as a web-based system to support delivery of curriculum, online teaching and learning, and sharing of knowledge across all Victorian Government schools (Department of Education and Early Childhood Development 2011b; Tatnall et al. 2013). It began its service to all Victorian Government schools in September 2010. It had many of the features found in a business extranet in that it was closed to people outside the Victorian Government school community and required a username and password to gain access, but with over 500,000 users, it was a good deal larger than most business extranets. The Ultraset's intended users were school teachers, as well as school students and their

School Management Software in a Primary School in Victoria, Use of, Fig. 3 EduPay (Department of Education and Early Childhood Development 2018a)

School Management Software in a Primary School in Victoria, Use of, Fig. 4 Program for Students with Disabilities (Department of Education and Early Childhood Development 2018b)

parents, all of whom would be issued with usernames and passwords.

The Ultranet was potentially an innovative technology that could have provided value to

the Victorian education system, but for a variety of reasons (Tatnall et al. 2013; Davey and Tatnall 2014), it was not successful and was discontinued at the end of 2013.

Compass

Many schools have taken on new student management systems to link in with other systems provided by the Department of Education. There are many companies providing these systems, under private arrangements with schools, but the Department of Education does not cover the costs of these systems. Compass (Compass Education 2018) was built and launched in 2010 as a software-as-a-service solution for schools. Compass is distributed by JDLF International Pty Ltd. with offices in Victoria and San Francisco. Compass is the emerging leader in online school and student management in Australia, providing schools with immediate, on-demand access to a student’s performance, well-being, and much more. In late 2010, they launched CompassPay; their merchant service division focused on incorporating streamline payment options to parents and students. Hurstbridge Primary School does not take advantage of this facility at the moment (Fig. 5).

Compass assists with roll marking and attendance, semester and progress reporting, news feeds and calendars, staff student and parent

portals, online payments and consent, resource and curriculum building, parent-teacher interviews, well-being and behavior management, event planning, budgeting and purchases, smartphone application, SMS and push notifications, parent communication, and more.

In Hurstbridge Primary School, Compass is used for communicating with parents. Once rolls are marked on Compass using the teacher’s laptop, smartphone, or tablet, SMSs are sent automatically to all students not present. Parents are then required to log into the Parent Portal to notify the school why their child is not present that day. Compass also sends parents notifications for all students who visit the sick bay, informing them what happened and what the school has done. Parents will be sent notifications when their child is out of uniform, when their Individual Learning Plans are completed or their school reports are available. Teachers are able to easily contact parents via email or SMS; parents also easily email their teachers to ask questions through the Compass Parent Portal.

Compass’s news feed allows the school to share information, forms, letters, etc. with all

School Management Software in a Primary School in Victoria, Use of,
Fig. 5 Accessing Compass on a smart phone

parents easily. The internal news allows for communication between staff at the school. A daily bulletin is shared with all staff informing them of what is happening that day at the school.

Updating information in Compass is very important; each night the school's administration system, CASES21, will update parent, staff, and student data into Compass, ensuring that data is up to date and correct. Student attendance data collected on Compass as well as student academic achievement data is updated back into CASES21 to be shared with the Department of Education.

EduMail

This exchange email system is based on Microsoft Outlook. Each teacher has their own email address provided by the Department of Education. Bulletins are sent weekly from the Department of Education to school management which then uses the system to forward these to each individual teacher. The Department of Education does not normally contact individual teachers directly via EduMail. School management has access to the management side of EduMail for their own school.

Almost everyone, of course, now makes use of email whether they use it for work or at home, and Victorian teachers are no different. The system provides each teacher with their own email address, and in addition to these individual staff accounts, the school also has its own email account. While at one time in the past the Department of Education used to communicate with schools and teachers via "The Victorian Education Gazette" printed monthly, in more recent times, a summary weekly bulletin was provided by Fax, but now everything is sent to the school by email.

Conclusion

What difference to school management and to teachers have these new systems made at Hurstbridge Primary School? The answer is that they have made a great deal of difference. Very little administrative output is now handwritten. This has made a quite dramatic change in the

way that the school office operates and changed the roles and tasks of office staff. The old cash-books are gone, and there is now no need for office staff to count or balance cash: office staff jobs are very different. Much more access to data is now available, and reports can easily be generated for each subject budget (which was very difficult in the past) and for any other account. This provides more easily accessible information, to both teachers and school administrators. All accounts and bills are settled by electronic payment, and parents pay any school fees via BPAY (an electronic bill payment system widely used in Australia). This makes quite a difference in the parent-school interface.

Parent communication has become a lot more transparent. All notices and information between the school and home is done via Compass. For parents this one platform provides them with everything they need in one place. They can also contact the school, book parent-teacher interviews, enrol their children into clubs, etc. through the Parent Portal. For the school, it is important that this is kept up to date, creating a new role in the school for a Compass Manager. For the classroom teacher, having all the information about their students in one location has made it significantly easier for their daily teaching. Parents also have notices, school reports, Individual Learning Plans, etc. easily accessible online at any time.

Although not all are compulsory, these systems are necessary for a school to operate efficiently today, and their use makes life much easier in a busy school environment.

Introduction

The world today is confronted with many socio-scientific and technological issues. Presley et al. (2013) defined socio-scientific issues as open-ended social problems with substantive connections to science. Zeidler and Nichols (2009) considered them as controversial in nature that require a degree of moral reasoning or “the evaluation of ethical concerns in the process of arriving at

decisions regarding possible resolution of those issues.” Sadler (2004) indicated that such issues are personally meaningful, require the use of evidence-based reasoning, and provide a context for understanding scientific information. These issues include climate change, use of nuclear power and gene therapy, human cloning, and the production of genetically modified organisms.

On the other hand, technological issues have been associated with the development and use of certain forms of technology. The use of information and communication technologies (ICT), for instance, may put some social processes at risk. Although ICT has improved social processes such as banking, marketing, and health care, they have become very dependent on the use of information systems, which could not be made 100% secure. Audestad (2005 as cited in Werlinger, Hawkey, and Beznosov 2008) suggested that one of the reasons for this is the complexity of the technology. “This complexity makes it difficult for the decision makers to manage the big picture and design security policies that cover all the possible configurations of the systems” (Werlinger et al. 2008). Hence, security testing has become a lengthy, complex, and costly process (Jiwnani and Zolkowitz 2002). Other issues associated with technological use include environmental degradation, pollution, addiction, and risk to safety.

These and other scientific and technological developments give rise to myriad of ethical, moral, and global concerns that threaten human dignity and survival (Choi et al. 2011). These make them essential sociocultural decision points since they are not only threatening human survival but also transforming the world economy, encouraging new patterns of social mobility and migration, and increasing interconnectivity between and within societies and culture. As Choi et al. (2011) indicated, “these concerns stretch from the personal to societal and global.” Hazelkorn et al. (2015) argued that these developments are “placing new demands on governments, educational institutions, businesses and civil society organizations to meet the evolving needs of society and the workplace.” The concerns that resulted from them can be solved “through collaboration,

communication, and cooperation between people who see themselves as members of a global community” (Choi et al. 2011).

These concerns call for producing citizens who understand scientific ideas, intellectual capabilities, creativity, and reasoning (Choi et al. 2011). There is a need to “nurture citizens with an awareness and respect of the issues and problems that exist throughout the world so that they can make important environment, health, and social policy decisions for themselves and the global community” (Choi et al. 2011). Science education provides the key towards this goal and technology could provide a platform in achieving this goal. But, the current social and technological landscape necessitates a review as to how science education should be approached. This entry aims to elucidate on how science education can be taught given the myriad technological changes and innovations in recent years, how it should respond to these technological advances, and how to harness technology to achieve these goals.

Science Education: Achieving Scientific Literacy

Scientific literacy is the common goal of science education. Science education should produce people who can think scientifically, apply knowledge to practice, critically assess information, and actively engage in an informed democratic dialogue about socio-scientific issues using valid evidences and scientific tools for reasoning (Siarova et al. 2019). Being a society influenced by information and technology, knowledge of and about science is essential to preparing people to be active and responsible citizens who can work collaboratively and communicate clearly the complex challenges facing society. As Alberts (2009) indicated, the knowledge of and about science can help people explain and understand the natural world, guide technological development and innovation, and forecast and plan their future personal and societal success.

Science education provides the knowledge and process of knowing things systematically in the natural world. An effective science education

facilitates students' learning of both the content and methodology of science so that they are able to design and analyze empirical investigations or utilize empirical evidences in constructing and refining explanations of certain phenomena (National Research Council 2007). Hence, the National Research Council (2007) described students who are proficient in science as students who can:

- (a) Know, use, and interpret scientific explanations of the natural world
- (b) Generate and evaluate scientific evidence and explanations
- (c) Understand the nature and development of scientific knowledge
- (d) Participate productively in scientific practices and discourse

Harrison (1982) suggested similar outcomes of science education. For him, an effective science education must provide learning experiences that develop a student's ability to discover and explore scientific phenomena, rationalize results of investigations, understand the integrity of the scientific process and knowledge, and explore the impacts of scientific knowledge on the perception of one's self, community, and the environment. Moreover, he sees a scientifically proficient individual as one who participates critically in decision-making about societal matters involving science and technology and understands the place of probability and statistics in science and in the analysis and resolution of societal problems. These outcomes emphasize the significance of the learning process rather than overloading the academic experience of students with facts, which they would most likely just memorize (Harrison 1982). Thus, the approach to science education must allow students to achieve scientific literacy, which is commonly used as the reason for studying science in schools (Brown et al. 2005) although as Fensham (2004) has indicated, it has received different interpretations from different individuals or institutions.

Holbrook and Rannikmae (2009) cited two views of scientific literacy, one from the camp of

those that advocate a central role for the knowledge of science and another from those who see scientific literacy with societal usefulness. The first view is grounded on the idea that science has concepts that are essential and that its content is a crucial component in scientific literacy (Holbrook and Rannikmae 2009). Maienschein (1998) considered it as a short-term view of knowing science, where its focus is more on knowing and understanding scientific concepts rather than on the capacity of the students to use these concepts for social use.

On the other hand, the second view looks at scientific literacy as a requirement for adapting to the rapidly changing world. As Rychen and Salganik (2003) suggested, this view sees scientific literacy aligned with the development of life skills such as reasoning skills in a social context. It recognizes that scientific literacy has little to do with science teaching solely for a career in science (Holbrook and Rannikmae 2009) but with science teaching that addresses social needs. In fact, it contended that social needs must be a major consideration in putting scientific literacy as a goal of science education. Németh and Korom (2012) reported that this view has received increasingly more attention over the past few decades than the first one. In fact, Holbrook and Kannikmae (2009) indicated that this view has been utilized to refute the need for specialized science courses in school. They cited that specialist courses are simply extensions of the generalist courses with an increase of "time on task" for more in-depth investigations. Thus, Németh and Korom (2012) suggested that general science courses are sufficient to develop students' skills and competencies that enhance awareness of the natural sciences, ability to apply knowledge in everyday life, and capacity for learning independently, acquiring information, and making decisions.

Given the gravity of the need for scientific literacy, Fisk (2017) suggested that science education must assume a new vision, one that promotes learners not only to learn the skills and knowledge of and about science but also to identify the sources from which they would learn these

skills and knowledge. Yager (2015) also suggested that these skills must aid individuals to explore the natural universe and explain the objects and events encountered as well as increase their economic productivity. It should likewise correct students' perceptions that "doing" science is only listening, interpreting, recalling, and/or repeating what they are told (Yager 2015).

The current technological landscape is expected to facilitate the achievement of these goals. For instance, the development and advances of Internet technology make teaching and learning resources accessible and available to teachers anytime anywhere. Wiesenmayer and Koul (1998) reported that the Internet stores a vast array of teaching materials such as graphics, sound files, lesson plans, documents, data, and software that teachers can access and integrate into their lessons. The presence of these readily available resources is expected to support teaching and learning of science. Teaching can become effective when diverse resources are being provided and teachers can readily access them (Odunlade 2017). The availability and accessibility of these resources will not only broaden the teachers' knowledge base but also prepare them for the challenges that will come along the way as they impart knowledge to students (Odunlade 2017). In recent years, Recker et al. (2013) reported that there has been a tremendous growth in the number of available Internet-based learning objects for teaching and learning as more free online resources were uploaded on the Internet in response to the open educational resources (OER) movement. This movement has allowed the proliferation of educational repositories of rich media on the Internet that can be used or reused for instruction (Perez 2017). This unprecedented growth in information resources on the Internet is seen to improve the way science is being taught. As Kumari (1998) indicated, the use of information resources on the Internet could require teachers to rethink the way they teach and/or create their lessons (Kumari 1998), and in so doing, they would improve the way they deliver science content to students.

Responding to Recent Technological Innovations: The IR 4.0

The recent technological revolution labeled as the fourth industrial revolution or IR 4.0 has significantly changed the world economy, just as the first three revolutions did in the past. According to Azmi et al. (2018), these four revolutions influenced not only the production itself but the labor market and the educational system as well. Schwab (2016) considers IR 4.0 as an unavoidable change that will affect every line of business and system of production, management, and control in almost every country. Frezzo (2017) emphasized that with IR 4.0, technology will play a central role in nearly all aspects of the society including education. With its impacts on the production system, IR 4.0 will demand new sets of competencies from students. Azmi et al. (2018) indicated that the expectations of industries and job market are usually influenced by society, economy and competition, and revolutions of industry. It means that demanded skills will change according to the revolutions of industry, although some skills may remain unchanged but should be enhanced to complement the needs of today's industry (Azmi et al. 2018).

Petrillo et al. (2018) identified three fundamental aspects of IR 4.0. The first one is the digitization and increased integration of vertical and horizontal value chains. This includes the development of custom products, customer's digital orders, automatic data transfer, and integrated customer service systems (Petrillo et al. 2018). The second one is the digitization of produce and service offerings, which involves the complete description of the product and its related services through intelligence works. The third is the introduction of innovative digital business models where high levels of interaction between systems and technology opportunities develop new and integrated digital solutions (Petrillo et al. 2018). These aspects have radically transformed the traditional industries by changing their approach to the work, i.e., extensive use of new production technology, new machinery, new materials, and new inputs. As Petrillo et al. (2018)

have indicated, knowledge has become an essential input in this new industrial context.

On the other hand, Capgemini Consulting (2014) implied that IR 4.0 is characterized by the merging of real and virtual worlds in cyber-physical systems. It involves the collaboration of intelligent machines, storage systems, and production systems into intelligent networks (Capgemini Consulting 2014). According to Lee et al. (2014), the cyber-physical system consists of an IT system being integrated with mechanical and electronic components that are connected to online networks to allow the communication between machines in a similar way to social networks. The very purpose for such innovations is to make factories “smart,” so that they can produce customized products on an industrial scale. Likewise, it is intended to create operational flexibility and efficiency so that many opportunities for improvements may be provided (Lee et al. 2014).

How work is done in IR 4.0 necessitates the development of technologies that can support the industries’ operations. Petrillo et al. (2018) identified nine main technologies that play important roles in IR 4.0. These technologies include big data, cloud computing, cybersecurity, automated robots, additive manufacturing techniques and 3D printing, augmented reality, horizontal and vertical integration technology, and simulation systems and software. These technologies are essential tools for maximization of the benefits of IR 4.0. Cloud computing, for instance, “allows [one] to manage huge data volumes in open systems and ensure real-time communication for production systems” (Petrillo et al. 2018) and “access to information from anywhere in the world at any time, thus increasing flexibility” (Haiping et al. 2014). In addition, the additive manufacturing techniques and 3D printing make it possible to construct prototypes, which in turn, make it possible to test the material to be used for the finished products (Petrillo et al. 2018). Moreover, instead of the old paper manuals that are difficult to understand, augmented reality is used to educate operators for maintenance or machine set-up (Petrillo et al. 2018). On the other hand, simulation systems allow the simulation of business

systems and manufacturing processes, which are important in analyzing these under study.

Clearly, these technologies and the advances in industrial processes require different prerequisites for their applications and operations, respectively. As IR 4.0 is being controlled by artificial intelligence (AI) and digital physical frameworks that make human–machine interface more universal, Shahroom and Hussin (2018) suggested that education should be able to harness pertinent information and abilities that could not be replaced by robots. Education should be able to prepare graduates for future life and work given that production systems under IR 4.0 would now consist of cyber-physical systems that make decisions and monitor the physical processes of factories (Bolat and Bas 2018). It means that the curriculum designed by universities should be able to produce holistic graduates with technical and nontechnical skills and sound ethics and morality (Azmi et al. 2018).

In responding to these requirements, science educators and education managers should revisit the curriculum of science programs and the approach by which science courses are being taught. As previously presented, the curriculum of science programs should be redesigned to produce holistic graduates. Azmi et al. (2018) defined “holistic” to consist of both technical and nontechnical skills and good ethics and morality. As part of the redesigning of the curriculum, they suggested the inclusion of industrial training in the academic curriculum in higher education institutions. They argued that the inclusion of such training in the university curriculum can provide an opportunity for students to apply the knowledge they learn in the lecture to the real workplace in the industry. Renganathan et al. (2012) also indicated that industrial training allows students to incorporate their work-related experience and knowledge into their formal education. In this way, students would be able to gain confidence and face challenges at work and in universities as well as develop skills necessary for teamwork, working under pressure, and dealing with people from all levels of the organization that are important in their future workplace (Pillai et al. 2012). It is necessary that universities develop these skills

among their students because, as Prifti et al. (2017) had emphasized, these are the skills that new industries would be demanding. Aside from the technical skills such as those related to information technology or information system, employers expect graduates to be equipped with behavioral skills such as collaboration, negotiations, customer orientation, networking, and communication (Prifti et al. 2017).

In addition to the curricular revisions, how science is being taught should also be taken into consideration, given the changes in the educational and technological landscapes worldwide. As the new industrial structure operates under the framework of the Internet of Things or IOT, it is imperative that science and technology learners develop an interdisciplinary framework. Aside from science being an interdisciplinary field by nature, science teaching should consider using interdisciplinary approaches to appropriately prepare students for the new characteristics of the workplace.

The networked nature of the new workplace under IR 4.0 underscores the importance of approaching science education with an interdisciplinary framework both in its content and pedagogy. You (2017) has emphasized the importance of shifting the teaching paradigm towards interdisciplinary approaches. According to her, the various science standards across the globe have already reflected this shift. Haseeb (2018) emphasized that the new industrial landscape will be situated at the intersection of disciplines such as technical, business, and science. Hence, he suggested that universities should be able to come up with interdisciplinary programs to produce graduates with interdisciplinary perspectives. Although You (2017) argued that science as a discipline is already integrated and not isolated, Cone et al. (1998 as cited in You 2017) suggested that it should be taught through an interdisciplinary approach so that students would be able to develop an integrated understanding of the complexity of the natural system or its corresponding scientific problems. Having an integrated understanding of complex systems is important to survive in a highly networked working environment where every system is highly

interconnected with each other (Sony 2018). A singular discipline may not be able to provide such understanding of the complexity of this integrated system or the real world as a whole (You 2017). As previously indicated, science disciplines are already integrated and not isolated; hence, separating them may create an artificial way to teach science, one that is not reflective of its true nature (You 2017).

Interdisciplinary teaching is defined as a process where two or more subject areas are integrated to foster enhanced learning in each subject area (Cone et al. 2009). It emphasizes cooperative and collaborative learning (Stier et al. 1994) that facilitates student engagement. As networking and interconnectedness are focal components of the new industrial landscape (Petrillo et al. 2018), developing cooperative and collaborative skills among the students is an important preparation for students. Expectedly, workers in such workplaces will collaborate and communicate real time without borders with intelligent machines (Petrillo et al. 2018). Thus, it is important that students should be trained on these requirements.

In addition, as interdisciplinary teaching provides a variety of ways to learn that are appropriate to a discipline, it promotes active learning among the students (Kaittäni et al. 2016). Active learning could facilitate higher order thinking such as problem-solving, critical thinking, and metacognitive reflection (Jacobs 1989; Newell 1994). Leblanc (1998) described it as an approach engaged with the tenets of effective teaching and learning. The National Science Teachers Association (2003 as cited in Kaittäni, Derri, and Kioumourtzoglou 2016) defined higher order thinking as the ability of the students to engage effectively in inquiry using scientifically defensible methods. Again, these are important skills in working with increased complexity of the job contents, a characteristic of the new or future working environment (Petrillo et al. 2018).

Several empirical studies (e.g., Eggebrecht et al. 1996; Cone and Cone 2001; Lattuca et al. 2004; Derri et al. 2010; Mueller et al. 2014) show the effectiveness of interdisciplinary approaches in students' cognitive advancement

and improvement of affective domains. For instance, Coskun and Demirel (2010) reported that interdisciplinary projects contributed to the development of students' abilities to make "connections between previously learned concepts, transferring what has been learned, and using the computer effectively as well as development of problem-solving, logical thinking, and communication skills." Also, Akins and Akerson (2002) observed that students exposed to integrated projects for an electricity unit have high interest in the subject matter. The projects required the use of language, arts, and skills of oral and written communication to plan the projects, and application of science knowledge to build the most effective design. Carmichael and LaPierre (2014) reported that interdisciplinary learning and learning community practices are effective in "promoting academic improvement, retention, development of general education skills, and high levels of student engagement."

Given these advantages of using interdisciplinary approaches in science teaching, You (2017) suggested that integrating various disciplines in the teaching-learning processes in science education should help students "develop a general core of knowledge that is essential for deeper understanding and knowledge connections." Newell (1994) also suggested that interdisciplinary teaching could increase students' understanding of multiple perspectives, which is important in appreciating implications for ambiguity and diversity. The importance of interdisciplinary perspectives as Kaittani et al. (2016) had emphasized is its capacity to bring together expertise from different fields in a way that retains and clarifies the fundamental building blocks of a given discipline. The approach could help students see and understand the connect between and among concepts and principles across various disciplines while they build up their disciplinary knowledge.

You (2017) summarizes and explains the wide range of desirable educational benefits for students and teachers of the interdisciplinary approach. She identified four important points about the benefits of using interdisciplinary teaching in science education as follows:

1. Interdisciplinary understanding facilitates higher-order thinking.

Higher order thinking has been hailed as the hallmark of scientific literacy (National Science Teachers Association 2003). Deeper understanding and multiple perspectives of knowledge are reflections of higher order thinking. Several scholars proposed that the integration of disciplines could help students develop a general core of knowledge that is essential for deeper understanding and knowledge connections (You 2017). Newell (1994) highlighted that interdisciplinary learning could lead to deductive reasoning and synthetic thinking by students. Lattuca et al. (2004) referred to the interdisciplinary teaching outcomes as "assisting students in developing complex understanding in a particular subject area, promoting the development of sophisticated views of knowledge, building students' capacity to recognize, evaluate, and use differing perspectives, engaging student interest, increasing motivation, and enacting constructivist and active learning strategies."

2. Integrated knowledge expands the explanatory capacity of knowledge and provides the additional richness of viewing the topic through multiple lenses.

Interdisciplinary teaching approaches develop students' deep understanding of concepts in a variety of distinct contexts and cognitive processes, which in turn helps them create links between their disciplines and other disciplines. In an interdisciplinary teaching environment, students can become "motivated by realizing that a single way of knowing is insufficient to understand the complexity of the natural world" (You 2017). As You (2017) explained, this would allow them to actively develop their own interdisciplinary stance on all sciences and "to demonstrate the full range of their understanding of science."

Lake (1994) made a similar stance when she argued that learners in programs taught with an interdisciplinary approach are guided to a deeper assimilation of cross-disciplinary concepts. It means, for instance, that students in an interdisciplinary program are expected to

complete a critical analysis of the connections between the artistic expressions such as in visual arts, music, or poetry, and the philosophical and political thought characteristic of an era (Lake 1994).

3. Educational scholars have suggested that interdisciplinary connections may make “learning easier... more realistic and potentially more useful to the student.”

Students might easily make sense of scientific issues and problems when they are presented with knowledge in an interdisciplinary perspective. As Entwistle and Ramsden (1983) have suggested, students who took a deep approach to learning would “seek meaning, reflect on what has been learned, and internalize knowledge by creating personal understanding.” With the multiplicity of perspectives and frameworks in an interdisciplinary approach, students would develop skills and knowledge associated with any of the relevant disciplines that could aid them to cope with real-life issues (You 2017). In addition, “teaching practices with an interdisciplinary approach can help students make sense of science regarding abstract scientific concepts and the role and function of science in modern-day society, which can encourage them to hold a more holistic view of real-world phenomena” (Fogarty 1991).

4. Several studies have been attentive to affective gains made in interdisciplinary learning contexts.

Empirical evidences indicate that interdisciplinary teaching develops positive attitudes and motivation among students toward learning. For instance, Bragaw et al. (1995) confirmed that interdisciplinary teaching produced positive values on students’ attitudes and motivation for learning. Barab and Landa (1997) made a similar observation when they reported that interdisciplinary curriculum and instruction motivated students to develop problem-solving skills. This is important because, as Singh et al. (2005) had argued, the affective factors drive students to action, where they initiate and direct purposeful behavior for evaluating their progress toward their goal. They

also provide a driving force for students to alter their behavior, if necessary, to ensure success at their desired level (You 2017).

Technology for Science Education

The current technological innovations could be harnessed to improve the delivery, management, and assessment of science education. Isman et al. (2007) believed that technologies can enhance students’ deep understanding of scientific concepts by changing what is abstract to concrete to make them easier to understand. This ability of technologies should be given due importance by science teachers to provide a productive learning experience to students in science education. Jowallah (2008) indicated that the use of technology in science teaching could help improve students’ involvement in courses, assuring their progress as active learners, and/or widen their independency and social interaction.

Roblyer (2003) defined educational technology as a combination of processes and tools that are used to address educational needs and problems. Educational technology could consist of two components, namely, processes and resources although most people think of technology as just the products (Smaldino et al. 2005). The processes are simply the learning activities necessary to achieve the learning objectives of the course while the resources are the tools used to enhance learning (Isman et al. 2007). As Newby et al. (1996) indicated, technology performs a bridging function between the theoretical explorations on the one hand and the real-world problems on the other. Thus, educational technologists should be able to design and redesign technological tools to address this concern. In science education, educational technologists should “use research method, pay attention to theory, plan activities, implement theoretical knowledge, and evaluate the application results so that they would be able to re-design the technological tools to achieve the goals of science education” (Isman et al. 2007). Roblyer and Edwards (2000) reported that such technology as the Internet, hypermedia, and big data had

significantly advanced the goals of science education by providing students with readily accessible information anywhere, anytime. Linn (2003) also stressed that technological innovations aid in formulating and re-formulating science instruction, creating new fields, and exploring impacts of new technologies. For instance, the rapid advances in information and communication technology had shifted the content delivery paradigm from teacher-centered to learner-centered to learning-centered. This shift has made the science learning environment more collaborative and interactive, which effectively increased students' interest for learning (Isman et al. 2007). Suduc et al. (2011) described this change as the evolution "from the formal transmission of information to an active process of knowledge acquisition, based more on the studying and understanding of practical aspects of a process than learning of the involved theoretical concepts."

There are several technologies that have supported the development of science education through the years. For instance, the development of light microscopy in the early part of the nineteenth century has transformed the way plant and animal tissues are being understood. With the availability of enhanced light microscopes, all plant and animal tissues were discovered to be aggregates of individual cells. The discovery of cells then has formalized the beginning of cell biology (Alberts et al. 2002), which was marked with the development of the cell theory proposed by Schleiden and Schwann in 1838. Since then, there has been a better understanding of the microscopic world as scientists continue to explore and provide information about it (Storksdieck 2015). Such understanding was advanced with the invention of the electron microscope (EM) in 1931 by the physicist Ernst Ruska and the electrical engineer Max Knoll. Today, the various EM-mediated studies provide a better projection of the microscopic processes and structures as EM makes subcellular structures and processes visible. Thomas et al. (2015) considered these advances as influential in the development of molecular biology.

Telescopes have also improved knowledge about the universe. For instance, it was instrumental in changing the Ptolemaic geocentric (earth-centered) view of the universe to the Copernican heliocentric (sun-centered) view. The Galilean telescope provided astronomical information that refuted the geocentric worldview of Ptolemy and established the heliocentric worldview of Copernicus. Because of the availability of telescopes, Johannes Kepler wrote his "Astronomia Nova" where he introduced the concept of planetary motion for the Solar System. Such work in 1609 has revolutionized the field of astronomy (Brown 2016). Since then, the use of telescopes in astronomical observations has increasingly become the norm. Today, a variety of telescopes are utilized to collect immense quantities of astronomical data that refine or refute the current understanding of outer space structures and processes. Robotic or remote telescopes are used to collect data about exoplanets or planets beyond the earth's solar system (Howell 2018). Among the discovered exoplanets so far, 51 Pegasi b, HD 209458 b, 55 Cancri e, HD 80606 b, and WASP-33b could provide information that could expand students' perspectives on how planets form and evolve (Howell 2018).

Recently, the rapid advances in ICT and its combination with other technologies have advanced scientific knowledge and processes. It also widens access to both the information generated through scientific processes and science education itself. It has made science education more inclusive, more attractive, and far-reaching, which is important in enhancing the scientific literacy of every individual in a society. As Suduc et al. (2011) emphasized, "the use of ICT in science education offers even more advantages due to the attractive premises to simulate and interactively explore and test experiments which would be too expensive or too dangerous in real settings (for example in nuclear physics)."

The combination of ICTs with microscopy has improved knowledge on biological processes at the gene level. Swedlow (2012) reported that combining the technical advances in microscopy with robotics has resulted in the development of

automated microscopes suitable for studying gene transcription. Using this technology, better information about gene action and its practical application has been obtained. As Swedlow (2012) reported, these microscopes are capable of recording cell phenotypes that result from systematic gene knockdown by RNA interference (RNAi). This information has allowed the development of RNAi technology that is used to screen drugs. Through RNAi technology, genes that can confer drug resistance or whose mutant phenotypes are ameliorated by drug treatment could easily be identified (Agrawal et al. 2003).

In relation to science teaching, ICT can be harnessed to support the administrative teaching tasks and the teaching and learning processes in a classroom (Tondeur et al. 2007). ICT can be utilized to support student administration, preparing worksheets, developing evaluation activities, keeping track of pupils' learning progress, etc. (Suduc et al. 2011). It can also be tapped to support and enhance the actual teaching and learning process (Tondeur et al. 2007). This could include the use of computers for demonstration purposes, drill and practice activities, modeling, representation of complex knowledge elements, discussions, collaboration, project work, etc. (Sang et al. 2010).

There are different ICTs that can be used to support science teaching and learning, and students should be able to construct their knowledge with activities supported by these technologies to enable them to become active in their courses (Balim et al. 2011). One of the technologies that is currently being implemented and continuously being studied for its application in education is artificial intelligence (AI). Reports (e.g., Popenici and Kerr 2017; Chassignol et al. 2018) have indicated that the use of artificial intelligence in science teaching has improved assessment and detection of learning and teaching gaps. With intelligent systems, assessing large numbers of assignments and detecting teaching and learning gaps are no longer a problem (Chassignol et al. 2018) albeit it might not be always true in all situations with no human interventions. In addition, the use of intelligent tutoring systems is

reported to increase productivity inside and outside a classroom (Chassignol et al. 2018). For students with learning difficulties, the use of AI helps them study more effectively and adapt to educational content through more individualized study plans. Individualized study plans are expected to address the differing students' pace of learning and understanding of instructions. Such differing pace could make students who are already ahead of the material easily bored, while others may be completely lost in new terms and phenomena (Chassignol et al. 2018). The capacity of AI to develop a more personalized learning environment could help resolve these issues.

The advancements of AI have also been tapped to create an inclusive science learning environment, where students who are physically challenged could still maximize their learning process. Assistive technologies such as text-to-speech, speech-to-text, zoom capacity, predictive text, spell checkers, and the like are some of the examples of technologies that are initially designed to assist people with disability (Popenici and Kerr 2017) though later their use has been expanded even to individuals who have no disabilities. Today, these technologies have augmented the learning interactions of students globally and can maximize their learning experiences. But it should be emphasized that although AI has enhanced teaching and learning processes, it cannot completely replace the roles of human teachers with students. In fact, Popenici and Kerr (2017) argued that despite the rapid advancements in AI, solely relying on these technologies for science teaching and learning is a dangerous path.

Augmented and virtual realities (A/VR) have also shown great potentials in enhancing science education. Furness et al. (1997) reported that the use of VR improves learning by providing the learners an experience of a phenomenon they could not have experienced before, either in direct interaction with the real world or using other technologies. On the other hand, Wu et al. (2013) reported that augmented reality systems support the visualization of abstract science concepts or unobservable phenomena, and have noted such affordances as learning content in 3D

perspective, ubiquitous, collaborative, and situated learning, immediacy, and immersion, bridging the formal and informal learning and visualizing the invisible in using it. Munnerley et al. (2012) reported similar observations. They emphasized that AR provides opportunities in relation to visualization, mobility, alternative perspectives, and comparison of multiple perspectives. Radu (2014) argued that allowing students to physically enact the abstract educational concepts through gestures, etc. will greatly increase their understanding of the concepts.

The Internet also plays important roles in teaching science such as in facilitating productive interactions, seeking new information, and aiding in research, dissemination of information, and extension of classroom instruction (Haury and Milbourne 1999). With Internet-based communication tools, teachers can extend their productive interactions with their students and others around the globe, especially those that share their interests (Haury and Milbourne 1999). This is a way by which students' interests in science could be maintained. In addition, being a storage of diverse learning materials, the Internet can help facilitate students' learning of new concepts and/or making of plans for a scientific project (Haury and Milbourne 1999). Indeed, ideas that could lead to the formulation of research questions may be searched from the Internet.

The capacity of the Internet to extend classroom instruction has gained popularity in the last two decades. Modalities of content delivery such as online learning or blended learning receive considerable attention from the academe as well as corporate institutions. Such extensions of instruction have widened access to science education. Renes (2015) mentioned that e-Learning in higher education has reached populations that were not commonly reached by the traditional modality. These populations include students with disabilities (Kumar et al. 2011), rural students who have difficulty relocating (de la Varre et al. 2010), parents with children (Mueller 2008), military personnel (Star-Glass 2011), and working individuals (Serrat 2010).

Although these technologies have contributed so much in the development of science education,

how effective they are for science teaching and learning depends on the properties of the tool itself, users' technological and pedagogical orientation, teachers' beliefs about the suitability of the tool, and the available support. As Salihi (2015) has emphasized, an effective use of a technology cannot be analyzed without the knowledge of the users of the tool or the context in which such a tool is being used. These factors should be considered to make science education effective in reaching its goal of increasing the scientific literacy of every society.

Concluding Remarks

Science education is playing an important role in societal development. It allows the development of individuals' abilities to creatively utilize appropriate empirically based scientific knowledge and skills that are relevant to their daily life and are useful in making socio-scientific decisions. Being a society influenced by information and technology, these knowledge and skills are essential in preparing people to be active and responsible citizens of a country.

Science education is continuously evolving, and in each evolution, technology plays an important role not only in terms of transforming its curriculum, delivery, and management but also in transforming its practitioners and learners. The rapid advances in technology, especially in ICTs, have transformed science teaching and learning, from highly teacher-centered to authentic learner-centered to learning-centered. Consequently, teachers under the new approach become more and more facilitators of learning and are expected to make learning more collaborative, personalized, and networked. This is necessary to prepare students for the challenges brought about by IR 4.0.

As the interaction of science education and technology has been proven to be essential in nation building, it is therefore imperative that a country develops its technological roadmaps. These roadmaps should direct its educational reformation to better address the current as well as future societal and industrial demands.

Security and Privacy of Information Technology Management Systems

Javier Osorio and Julia Nieves

Synonyms

Data protection

Definition

Information security is usually defined as a feature of information systems management which involves three main aspects, named confidentiality, integrity, and availability (Lov om behandling 2000; ISO/IEC 27002:2005 2005; ISO/IEC 27000:2009 2009). Usually, quality is included as a fourth aspect of information security, although it can be considered as overlapping with integrity. The following is a brief definition of these items: (a) Confidentiality is the guarantee that information is not made available or disclosed to unauthorized persons, entities, or processes; (b) integrity relates to the trustworthiness of the information, thus assuring that data has not been deliberately tampered with, nor accidentally changed; (c) availability means that information is accessible and can be utilized upon demand by an authorized entity; and (d) quality refers to the information being correct and not misleading. Among the aforementioned aspects, confidentiality is particularly important because of the sensitivity of personal information. Associated with security, privacy emerges as an issue because of the right to privacy with respect to the processing of personal data. In this way, regarding the relationship between security and privacy, the latter could be defined as the right of the client and the former the duty of the service provider (Henriksen et al. 2013).

Security

Introduction

The security of information technology (IT) is a matter of great importance for organizations. One important reason is the continued use of IT by different stakeholders and the large amount of information stored, sometimes critical to the organization or its customers. Education centers are not oblivious to this type of problem, with the main characteristic being that the clients, in this case, are the students who study at the center, and the sensitive information is of a mainly personal

nature (Culhane et al. 2018). Thus, the management of education centers is faced with a problem for which they are responsible as top management of the organization but for which they have often not received training. Many of the aspects related to the assurance of information security are fundamentally based on technical issues, with which many school directors feel uncomfortable. However, this lack of knowledge or discomfort cannot be a pretext for neglecting this important aspect of the management of information systems (Weng and Tang 2014). The directors and top managers of education centers and institutions must be aware of the implications of guaranteeing the security and privacy of the information they are responsible for as leaders of their organizations.

Education centers, regardless of the level of education they provide (primary, secondary, or higher education), which utilize information technology (IT) infrastructure must guarantee its normal functioning, especially when a large part of their daily operations is based on the use of information systems and technologies. Errors and cyberattacks, both internal and external, can prevent its proper functioning. For this reason, it is crucial to have a security policy that includes actions to prevent errors or attacks from affecting the technological infrastructure. However, this policy should not be considered as optional since there are issues related to the safeguarding of privacy which are protected by law. Therefore, this issue becomes a mandatory element in the agenda of decisions and activities of those responsible for education centers and institutions (Brockmeier et al. 2005). In addition, the problems that education centers encounter in this area, although in many cases they are public, non-profit institutions, are the same as those faced by companies and organizations of all kinds that make use of information systems and technologies as part of their daily activities. The above is, however, an opportunity for schools because advantage can be taken of the great volume of knowledge generated in terms of the security and privacy of information systems and technologies in the business field.

The main aspects that should be considered in terms of the security of information systems within any organization, and therefore in educational organizations, are the following (CAP Gemini 2000): (i) errors due to a malfunction of hardware or software, (ii) errors due to IT users, (iii) natural catastrophes, (iv) unauthorized access by external or internal personnel, (v) deliberate damage done by staff or by strangers, and (vi) deterioration due to aging or everyday use of infrastructure.

Policies and Procedures

Establishing policies and procedures related to the security of the IT infrastructure is a key issue that managers of any type of organization must face. The significance of this issue increases in environments where computers are connected through communication networks, whether internal or external. In this situation, to the physical threats are added the risks that arise through communications, either in the form of unauthorized deliberate access or by the introduction of harmful software (viruses) into the system.

Each organization should establish a security policy and communicate it to all staff. The policy should be the result of an analysis of the potential risks to which the organization may be exposed. The purpose is to protect the assets of the organization, in this case, data and information about the different stakeholders of the education centers; for this objective, the collaboration of those affected should be encouraged, i.e., teachers, administrators and technicians, as well as parents and students. The security measures must be coherent, and a key factor in obtaining the commitment to execute security procedures is to make them practicable. The people involved will most likely not accept procedures that make their work practically impossible and, if this were the case, in all likelihood they would end up using their time and ingenuity to bypass such controls. Therefore, impractical conditions raise the risks instead of decreasing them. The IT infrastructure cannot be protected by technical means alone; it is also necessary to have a security plan with the guarantee that people involved in IT are aware of and act

to adhere to the general security policy (Culhane et al. 2018).

The responsibility for security matters rests with the management of the center and, in the case of delegation, the person in charge of the IT department, assuming there is one. The responsibilities that are acquired include (i) the prohibition of the use of unauthorized software, (ii) the implementation of the physical security process, (iii) the availability of procedures that prevent unauthorized access to the center's IT systems, and (iv) responsibility for the integrity of the data. One of the most important missions of the IT infrastructure security manager is to raise security awareness in all stakeholders. This is because success in this matter depends on procedures being followed, and this is only possible when there is full awareness. For this to be achieved, a culture of security must be created, which can be materialized through campaigns based on messages and information on this issue. The staff of the center in direct contact with IT must be the first recipients of this type of message, in which the need to protect the information and the IT infrastructure used in the center must be highlighted, as it is part of their work routine and, therefore, fundamental to the correct development of teaching tasks.

A very useful tool for checking the security of the IT infrastructure at the center consists of the regular practice of auditing the procedures and their level of effectiveness in terms of computer security. Essential aspects to evaluate as part of the audit include (CAP Gemini 2000) (i) access controls to the IT systems, (ii) physical access controls to the facilities in which the electronic devices are located, (iii) protection against physical threats, (iv) data integrity controls, (v) generation of backup copies, and (vi) security awareness procedures. The following is a set of factors recommended for consideration in defining security procedures. They cover a wide range of cases, and it must be the director or head of security of the center who establishes the degree of development of each one of them (for a greater development of the concepts, it is recommended to go to a computer security manual published by consultants or IT manufacturers).

Physical security. The protection of the IT infrastructure depends on the physical conditions in which computer systems and communication networks operate. There are also other risks, such as fire and flood, that are beyond the physical characteristics of the IT infrastructure, but that need to be considered. The storage of documentation and magnetic supports deserve special mention due to the importance of ensuring their protection. Aspects to take into consideration related to physical security are electrical protection, fire risks, natural catastrophes, urban disorders, and buildings and facilities outside the center susceptible to generating hazards (gas stations, bus stations, high density traffic routes, railways, etc.).

Physical access. One way to ensure security is by restricting access to the room in which sensitive equipment is located, such as servers or communication racks. Access to this equipment allows control over the system, so protocols should be established to prevent unauthorized personnel from accessing the equipment. Access by authorized personnel should also be monitored. Aspects to take into consideration related to physical access are security controls in the areas of access to sensitive equipment, the use of booths or security boxes to store documentation and magnetic backup media, and security keys and protocols for control of access for both internal and external personnel (maintenance technicians).

Access to computer applications. Access by an unauthorized person to the information systems housed in an education center is a crime, and, as such, those who commit it can be reported and prosecuted. However, education center managers must articulate policies and procedures, directly or through specialized technical services, internal or external, to protect the IT infrastructure from unauthorized access. The nature of the information available in the center's databases and applications, and the possibility of accessing them through internal and external networks, makes this a critical point of IT security. The main requirement is to develop mechanisms

that ensure that only authorized users can access computer systems with user identifiers and defined passwords. The first, identifiers, constitute a main component of computer security. It should apply to both people and terminals. Each user must have an identifier to control their access rights, privileges, available resources, and access to sensitive information. For this reason, user identifiers must be assigned individually. The second key mechanism to ensure that no unauthorized person accesses the information systems of the center is the use of passwords. As far as this question is concerned, a password policy should be established, known to the users of the systems, which includes the characteristics of the password itself (length, type of characters) and the duration of its validity.

Installation of unauthorized software. The installation and use of unauthorized software pose many risks, both for potential infringement of intellectual property rights and for facilitating security breaches. Many unauthorized downloads come from internal personnel or from the organization's suppliers of IT equipment. It is often the case that the staff of education centers, whether due to dissatisfaction, boredom, or other reasons, add their own software to compulsory use programs for purposes unrelated to the requirements of their work. This software can lead to easy entry into sensitive parts of the information system, unauthorized operations (e.g., Trojan horses), or the installation of computer viruses into the center's systems. Installation of unlicensed software can damage the reputation of the organization if it is made public that this type of software is being used. The center can only be protected against such threats when users only make copies of the licensed software or obtain copies from external sources through control procedures. All users' computers should be audited and clear guidelines must be set to establish exactly which software applications can be approved for installation.

Network security. The systems are usually connected through communication networks,

both internal and external through the Internet, which generate threats to security. The risk comes from, among other sources, unauthorized access from outside and the installation of malicious software that may negatively affect the proper functioning of the IT infrastructure. The use of encryption systems, passwords, and advanced authentication systems through digital signature, firewalls, antivirus programs, etc. can decrease, although not avoid entirely, the potential risks derived from the use of communication networks. One of the least known forms of risk regarding the use of networks, especially the Internet, is the infringement of intellectual property. This could be the case regarding the information shown on the education center's official website. In this sense, part of the information present on the website may come from sources that are the intellectual property of third parties. On the other hand, there may be teachers or staff from the center who use material obtained on the Internet with registered copyrights. In this sense, it is important that all members of the organization become aware of the potential dangers of violating intellectual property laws, in addition to those mentioned above on safety.

Privacy

Definition

Privacy in the field of IT is understood as limiting the use of information systems to guarantee the honor and personal and family privacy of citizens and the full exercising of their rights (Schwartz 2004). Under this definition, of a broad nature, some related aspects can be circumscribed, such as (i) personal data, referring to all information about an identified or identifiable person, that is, whose identity can be determined directly or indirectly; (ii) processing of personal data, which is any operation or set of operations carried out (or not) by automated procedures and applied to personal data, such as collection, registration, modification, consultation, communication, suppression, or destruction; and (iii) personal data

file, i.e., a structured set of accessible personal data according to certain criteria, whether centralized or decentralized.

Introduction

The use of modern means of information processing and communication, with a huge capacity to process information of all kinds, has given rise to a growing concern for the security of IT infrastructure, mainly because of the damage that can be caused to the functioning of the organization derived from fraudulent access or use. However, it should not be forgotten that much of the information that is stored in the information systems is personal, that is, it affects personal privacy and the freedom to make decisions regarding the automation and transmission of personal data. Therefore, the security of IT infrastructure and privacy are two closely related areas, and each must be considered as complementary to the other in the management of IT. For the specific case of education centers, it is a function of educational management teams to ensure that not only are security policies and procedures established, but also that compliance with privacy requirements is ensured, given that there are numerous laws that establish compliance with minimum requirements which, if not met, is considered a crime.

Privacy or data protection is an issue that has acquired a high profile as a consequence of the continuous development of information processing systems, as well as the transmission of information through all types of networks. The right to personal privacy, which can easily be violated through these devices, has led to growing interest. This issue has been, for a long time, the remit of the courts, materializing in a series of national or supranational laws on the protection of the privacy of individuals' information. For educational managers, this question is of great importance because in schools there is a very sensitive group, namely, students. A large amount of personal or other information (academic, attitudinal, aptitude) is handled by these organizations, and irresponsible use of it is not only subject to sanctions but can also cause great moral damage. When dealing with information

about minors in the case of schools, these considerations are all the more critical.

The set of terms and procedures related to privacy acquires special relevance in the figure of the controller, which is the person or public authority responsible for determining the purposes and means of processing personal data. Educational management teams have, therefore, the maximum responsibility in this matter and are in charge of establishing the procedures and policies that have to be communicated to all the members of the organization for compliance with the privacy directives (Akbaba-Altun and Güler 2008).

Legal Basis

Electronic communication and the storage of personal information are subject to national legislation and, in some cases, such as with European legislation, to supranational legislation. Examples of this are the EU directive on the processing of personal data for the countries of the European Union (Directive 95/46/EC 1995) and the Health Insurance Portability and Accountability Act of 1996 (HIPAA) in the United States (Health Insurance Portability and Accountability Act 1996). Standardized procedures compiled as international ISO standards on best practices for the establishment of information security techniques and IT have also been developed (ISO/IEC 27002:2005 2005; ISO/IEC 27000:2009 2009).

Recommended Actions for Managing the Privacy of Information in Educational Environments

The work of the management consists, first of all, of establishing the necessary technical and organizational measures that must be implemented for personal data files, equipment, and information systems, as well as ensuring that the people who intervene in the processing of this data comply with the privacy requirements as established by law. The recommendations established in the ISO standards on information technology security techniques are also useful for this function. The person in charge of the treatment of information is the director of the educational center, who, in the

case that they need support for these functions, can formally delegate the function of coordinating and controlling the required security and privacy measures (Wilk 2016). The following is a summary of recommended actions:

Security document. A first action in this matter is the development and implementation of security regulations to ensure the privacy of information. This is done through a mandatory document for staff with access to automated personal data and information systems. Said document should contain the following aspects: (i) scope of application, with detailed specification of the protected resources (automated data files, equipment, systems, programs, people intervening at some stage of the process); (ii) standards and procedures to guarantee the required level of security; (iii) staff functions and obligations; (iv) structure of the files with personal data and description of the information systems that treat them; (v) procedure for notification, management, and response to incidents; and (vi) procedures for making backup copies and for data recovery. The document must be updated and revised whenever there are relevant changes to the information system or to the organization thereof. Its content must be adapted at all times to the current legal provisions regarding the security of personal data.

Functions and obligations of the staff. The functions and obligations of each person with access to personal data and information systems will be clearly defined and documented. The personnel must know the safety regulations that affect the performance of their functions, as well as the consequences that could be incurred in case of non-compliance.

Incident registration. The notification and incident management procedure will necessarily contain a record stating the type of incident, the time it occurred, the person making the change, who is notified, and the effects that would have been derived.

Identification and authentication. The personal data security officer will ensure that there is an updated list of users who have authorized

access to the information system and establish identification and authentication procedures for said process.

Access control. The users will have authorized access only to the data and resources that they need for the development of their functions. In this sense, within the scope of teaching activities, teachers should be prevented from accessing sensitive personal data if it is not for a justified reason that affects the exercising of their teaching duties, in which case it will have to be done through a formal request. The information handled by teachers, in general terms, must be of an academic nature. Similarly, the administration staff, who habitually work with the personal data of students and their families, should have some kind of restriction on access to academic performance data. The officer responsible for the file will establish mechanisms to prevent a user from accessing data or resources with rights other than those authorized.

Management of data storage devices. The electronic devices that contain personal data must be able to identify the type of information they contain and be inventoried and stored in a place with access restricted to the personnel authorized as set in the security document. The movement of electronic devices that contain personal data outside the premises in which they are stored may only be authorized by the person responsible for the file.

Backup copies. A procedure for making backup copies and recovering data must be established. These procedures must guarantee their reconstruction in the state in which they were at the time of the loss or destruction. Backup copies should be scheduled periodically, at intervals that depend on the volume of updated data.

Summary

The right to information privacy and the security of the IT infrastructure is a matter of great importance that, however, has not traditionally received enough prominence in the agenda of educational

managers. Among the set of functions assigned to educational managers are also included those involved in information management and IT. Education centers generate and store a large amount of personal information, which can have negative implications for people's lives if they are misused. The laws on data protection and the right to privacy oblige educational managers to establish security protocols to safeguard people's right to privacy. For this reason, educational managers must assume this responsibility as part of their work. For this, they can rely on qualified personnel and on the wide range of recommendations and guides developed by national and international companies and organizations on information security and IT infrastructure. Each education center, according to its circumstances, must elaborate and comply with a security policy which is known to all the people who work at or have a relationship with the center and which includes coherent and practicable security measures.

Introduction

Very few digital games can be described as a cultural phenomenon. From players that identify as “gamers,” extending a sphere of influence to anyone with a passing interest in mainstream popular culture (Thompson 2016), it is remarkable to consider how the independently developed game, Minecraft made its impact on mainstream popular culture. One of the key reasons often attributed to this success was its accessibility to a range of audiences and the affordances that it provided users to “play the game” in the manner of their preference (Zolyomi and Schmalz 2017). Minecraft is the rare game that can be almost all things to all players. It was designed to be shared.

While Minecraft can be played as a single player experience, it was most popular as a

multiplayer, online game (Zolyomi and Schmalz 2017; Thompson 2016). The increased interactions and socialization between players have inevitably contributed to increasingly sophisticated instances of social interaction, and this is an area that has received increasing academic attention. Research has been undertaken into the different forms of collaboration between players engaged in multiplayer games, particularly in relation to massively multiplayer online role-playing games such as World of Warcraft (Uz and Cagiltay 2015; Chen 2012). A key social skill for successful collaboration is social regulation, which can be thought of as the processes for controlling behavior within group interactions. This encyclopedia entry unpacks the concept of regulatory planning, a key process within an established conceptualization of social regulation (Grau and Whitebread 2012), illustrated using two different modes of multiplayer play in Minecraft.

Viewing Minecraft as a Tool for Collaborative Creation

Minecraft was originally conceived by its developers as a simplistic sandbox game, where a player would freely create, locate, and destroy objects called blocks. This form was known as a “Creative Mode,” which presents an open-ended space with no specific objectives or ending. The subsequent “Survival Mode” was soon released, a mode of play that encouraged players to mine resources and construct fortifications to withstand the damaging advances of “creeps,” or challenging hordes of creatures. As Minecraft began to transcend its origins as a niche independent game project and became a mainstream cultural phenomenon, many game players focused their output almost exclusively on building, sharing, and showcasing their creative designs. The addition of more sophisticated design components in subsequent updates to the game allowed players to add functions and automated macros to the static environment. Minecraft was coded in the platform agnostic computer language Java that encouraged players to contribute and share their own content. The affordances offered by these additions allowed the

design of automatic doors, context-dependent lighting, and the creation of complex mechanical components such as pistons.

Minecraft has been used as a research tool for exploring understandings of such diverse domains as spatial geometry (Foerster 2017), sustainable planning (West and Bleiberg 2013), digital storytelling (Garcia Martinez 2014), social skills (Petrov 2014), informatics (Wagner 2015), computer art application (Garcia Martinez 2014), project management (Saito Takebayashi and Yamaura 2014), and chemistry (Hanc1 2012) and artificial intelligence (Aluru et al. 2015).

The ongoing cycles of design modification and changing player behavior have resulted in Minecraft evolving into a more complex space for collaborative creativity and expression. The release of a server-based multiplayer feature made it possible for many players to work together, or against each other, with an online environment that appeared almost boundless. In a virtual gaming environment with a creative mode such as Minecraft, when players interact and collaborate, then they will consequently plan and regulate their behavior while negotiating, setting goals, and developing sub-games.

Conceptualizing and Capturing Instances of Self and Social Regulation

There has been a shift in the thought surrounding how regulations of cognitive and metacognitive processes in learners are understood, particularly in the field of educational psychology. Regulation has traditionally been described as a process at the individual level, contained to the “self,” with a focus on the child’s own cognitions, emotions, and behaviors (Hadwin et al. 2011). There has been a move away in the literature from such models of self-regulation towards a social understanding of an interplay between regulation at an individual level and a co-constructed social level (Hadwin et al. 2011; Volet et al. 2009; Vauras et al. 2003). These theorists no longer conceptualize students as isolated silos. This shift reflects the emergence of a sociocultural model of cognitive development, emphasizing the essentially social

nature of learning. This increased emphasis on social learning, particularly in regards to collaborative problem-solving, has resulted in new models to explain the regulation of individuals within these group contexts that exist outside of the boundaries of self-regulation.

- *Co-regulation* is a regulatory process that is intended to influence the “cognition, motivation or behavior of one specific member” of a group (Grau and Whitebread 2012, p. 411). This can be seen through the lens of a master-apprentice relationship or expert-novice tutoring relationship, where a “more knowledgeable other” guides a relatively less knowledgeable or skilled individual in solving an equation, or finding the right note on a musical instrument.
- *Shared regulation* is a regulatory process that is “more related to group planning, monitoring and regulation” of a shared activity, characterized by multiple group members interacting with each other to achieve a common goal (Grau and Whitebread 2012, p. 411). Despite this commonality of purpose, this form of regulation may still retain imbalances between participants in relative knowledge, skills, and social capital (Hadwin et al. 2011).

Grau and Whitebread (2012) discuss the interplay between these three forms of regulation, contending that all three are active, often simultaneously, in the collaborative planning, monitoring, regulation, and evaluation of group activities. Figure 1 visually represents the relationships between self-regulation at an individual process, co-regulation as a bilateral process, and shared regulation as a socially constructed co-process occurring during multilateral interactions. The focus is on the social levels of regulation, “co-regulation” and “shared regulation.”

As can be seen in Fig. 1, both self and social levels of regulation are conceptualized as consisting of four subprocesses spanning the planning, regulating, monitoring, and evaluation of behaviors. Focusing just on the shared planning processes within this model, Table 1 examines planning processes in three different contexts: planning the completion of a common task, planning the

Shared Regulatory Planning in Minecraft, Fig. 1 A visual representation of the self and social levels of regulation, as described by Grau and Whitebread (2012)

Shared Regulatory Planning in Minecraft, Table 1 Describing the planning processes within joint activities, as listed in the model by Grau and Whitebread (2012)

	Planning processes
Task	Planning the task
Indicative behaviors (<i>What does this look and sound like?</i>)	Talks about the relevant content knowledge that should be applied in the resolution of the task Talks about his/her knowledge about strategies or personal resources that can be used in order to solve the task Talks about setting goals Establish task-specific goals that can be used to guide cognition and monitoring Formulates a step-by-step strategy before solving a problem Propose a way of solving the task or a way to start doing it
Organizational	Planning the organization of the group
Indicative behaviors (<i>What does this look and sound like?</i>)	Students plan the organization of the task in a pragmatic level (who is going to do what)
Socio-emotional	Planning socio-emotional interactions
Indicative behaviors (<i>What does this look and sound like?</i>)	None provided as Grau and Whitebread reported they did not observe any instances of socio-emotional planning

organizational structure of the group, and planning the socio-emotional components of the interactions.

The use of this established model serves dual overarching purposes in helping to understand shared regulatory planning:

1. It provides a framework to capture and explore instances of social regulation in collaborative play in player created artifacts within the Minecraft community.
2. It allows for the exploration of the boundaries and tensions within Grau and Whitebread's (2012) when applied to a virtual environment.

Recording video and audio has been used as a tool for capturing a time and place, affording the identification of shared regulation with Science classrooms (Grau and Whitebread 2012) and exploring social regulation through the analysis of publicly shared footage from multiplayer Minecraft games (Harrison et al. 2018). Self-regulation is notoriously difficult to observe during a solo activity and a challenge to capture, relying on recording "self-talk" during a solo activity or asking the player to reflect or comment on their own performance. By contrast, in Minecraft, there are clearly identifiable instances when a player regulates their social behavior while planning, either as co-regulation with another player or shared regulation between multiple players. Instances of regulatory processes during joint activities have been observed by analyzing verbal and nonverbal communication between participants (Whitebread et al. 2009).

Exploring Shared Regulatory Planning in Minecraft

As is now increasingly common within gaming culture, Minecraft players and users often capture and share a recording of their game session using screen capturing software to stream live or publish the session to a video sharing service. These public recordings and gameplay artifacts are freely shared online. Not only do these invite feedback and comment but also they are a cyber-ethnographic opportunity to examine the community and culture created through computer-mediated social interaction.

The accompanying player narration is often deeply personal and may widely vary in style and nature from shared laughter, dialogue with other plays, to that colored by profanities or filled with obscure jargon. Players within the view of each other can draw attention or emphasize something by moving in unusual ways such as wildly jumping on the spot or gesturing. Another, albeit slower option is to type and broadcast a text message to other players. While online games are rich in visual images and audio messages, the option for feedback by nonverbal communication is limited. Despite this limitation, instances of shared regulatory planning where multiple players are interacting, collaborating, and competing are quite common. This is illustrated in Table 2 by the following different sub-games or gameplay modes: Game A, a "Team-Build," and Game B, a game of "Capture-The-Flag."

Game B involved a more action-orientated mode of game play that required players armed with arrows to engage in medieval combat in a castle setting, attempting to secure the position of the enemies and return it to a home base for points. Points were also awarded for mortally wounding members of the opposing team, causing the deceased to wait a period of time before "respawning" near their own base. Screenshots from these two modes are shown in Table. 2. The differing modes of play impacted upon the team and individual goals, and the rules around interacting with the other teams. Players in Game B could interact in the virtual environment and through text-based chat with their opponents, while in Game A players can only interact with the other teams once the building phase was completed. Focusing specifically on verbalizations or behaviors relating to "planning," there are some interesting contrasts and some surprisingly similarities between the frequency and nature of planning in the two modes of play.

Understanding Regulatory Planning Through Motivation

Grau and Whitebread (2012) describe three sub-categories of planning which may further help in

Shared Regulatory Planning in Minecraft, Table 2 Contrasting two different modes of Minecraft game play

Game A: Team-Build (Gamer Chad 2018)	Game B: Capture-the-Flag (Bajan Canadian 2014)
In this Minecraft game, several teams of players are challenged to construct something around a set theme within a designated time limit and concluding with a vote. The theme this <i>team-build</i> game is about SpongeBob SquarePants, an animated television series created by marine biologist and animator Stephen Hillenburg	In this Minecraft game, two player teams coordinate a competitive game challenge to capture the opposition’s flag on a randomly generated map. It is a variant of a traditional outdoor game where team’s race to <i>capture-the-flag</i> located at the other team’s “base,” then bring it safely back to their own base
	

understanding the implicit motivations underpinning these observed verbalizations and behaviors. One framework that has been used for examining player motivation specifically in online gaming is Filsecker and Kerres’ (2014) Volitional Construct Framework. This framework conceptualizes motivation “as a volitional process” (Filsecker and Kerres 2014, p. 456), which can be understood as a system of psychological control processes that allow individuals to stay focused on achieving a goal and to ignore distractions that are not related to achieving that goal (Filsecker and Kerres 2014; Kuhl 1987). These goals may be a joint team goal in the game, such as winning the Team-Build vote in Game A, or scoring higher than the opposing team in Game B. These goals may also be individual goals, such as building a particular structure in Game A, or one player having a higher individual score compared with the rest of his or her team.

With the use of publically shared artifacts from an online video service, such as YouTube, comes a third meta-goal, attracting more viewers to gain increased revenues. When prioritized by the player, this third meta-goal can result in players acting in a way that seems counterintuitive in achieving the first two goals. It is only when placed in the context of attracting a viewership through providing something “out of the

ordinary” such that running into an enemy base unarmed begins to make sense. This goal-driven understanding of motivation helps us to understand shared regulation when planning the approach to the task, the organization of the players, and the socio-emotional state of individuals within the team.

Examples of Players Being Motivated by Task Planning

The first of these subcodes is *task planning*. This centers around any verbalization or behavior that refers to actions that should be carried out in the future to help achieve the task or team goal. The coding scheme provides number examples of social planning processes being utilized in the context of planning how to approach a task in a primary school Science group activity. These examples provided a series of indicative behaviors or descriptions of what task planning may look like “in action” (Griffin and Care 2014). These are useful in considering what these processes in a games-based context may look like.

Setting the Team Goals

Working towards joint goals requires significant negotiation and planning to manage individual and team objectives. The steps for achieving this and the activation of relevant prior content

knowledge (Grau and Whitebread 2012) is best illustrated using the instances of task planning as outlined in the following two different games in Table 3 below.

When talking about the goals at the start of a game, players will often communicate the goals of the scenario or mode of play. It is a chance to focus a team towards the same mission then ask questions to ensure understanding of the rules or to align personal goals with this team goal. Most of the modes within Minecraft provide a clue as to the goal through the naming of each particular mode. For example, the aim of a game called “Capture-The-Flag” is fairly self-evident. When a team member in Game B reported back that “*Okay I see it, I bring in a flag from that thing,*” they were paraphrasing the goal to confirm their understanding. Whilst the discussions that then followed explored various weapon strengths and access staircases, an important planning alignment had been first undertaken with other team members with the main goal which was established through the design of this mode. This is confirming of the goals for a particular mode of

play is also observed in other modes, such as the Team-Build mode being used in Game A:

*... our theme is SpongeBob ... and we're gonna do (um) like .. where they live and stuff.
... I want to build (um) Patrick's house too.
... Didn't we literally are going to make this Bikini Bottom?*

There is a substantial difference between the nature of the goals being discussed in this example of dialogue and the goal used in the previous example. In the example drawn from Game B, the players are discussing a goal that is established through the design of the mode; it is a goal set by the rules of the game. This second example in Game A discusses a goal that is negotiated by the players; it is a socially constructed objective that fits within the affordances of the Team-Build mode of play. It still draws on the conventions of this mode, as the players are arguing what they will build with the objective of achieving the goal set by the mode of play, winning the end of game vote. This raises an important consideration in analyzing goal setting within multiplayer digital games; game design sets the overarching goals of

Shared Regulatory Planning in Minecraft, Table 3 Examples of instances of task planning observed in Minecraft play

Indicative behaviors from Grau and Whitebread (2012)	Game A: Team-Build (Gamer Chad 2018)	Game B: Capture-the-Flag (Bajan Canadian 2014)
Talks about setting goals	“..our theme is SpongeBob .. and we’re gonna do um like .. where they live and stuff.” “... I want to build (um) Patrick’s house too. (Yeah yeah you) Didn’t we literally are going to make this Bikini Bottom?” (t = 2 m 55 s)	“Okay I see it, I bring in a flag from that thing.” (t = 2 m 24 s)
Formulates a step-by-step strategy before solving a problem	“This is the road Dollastic. Okay, which way do you want it to go? ... Like that way? So right here, you’ll put Sergeant’s house” (t = 33 s)	“Hey guys. Okay, let’s all go down mid. (t = 8 m 53 s) “I’m going, I’m going around. I went around the whole map, I’m sneaking into their base” (t = 9 m 11 s)
Talks about his/her knowledge about strategies or personal resources that can be used in order to solve the task		“So it’s a neutral game so far, I’m at imagine your spawn is just on where they’re running to. It’s great that spawn point” (t = 4 m 45 s) “I get back to the flag faster anyways. That’s actually legit strat, you could suicide and get to the flag quicker” (t = 8 m 30 s) “I’ll be I’ll be a body bag.” (t = 9 m 00 s)

a game, and the boundaries around what is possible, but in many modes of play also encourage a degree of negotiated interpretation by the players.

Pendulous Decision-Making

A player in Game A opened by stating that the team-build game theme was *SpongeBob*. The player then sets out what the other team members will do and gave a clue about the scope of this project, “*where they live and stuff*.” This is quickly followed by a remark by another player that begins to explore a smaller personal goal or house that they want to work towards. This then prompts a further clarification about the central mission “*Bikini Bottom*,” a collection of homes that make up a small city set within *SpongeBob*. The planning at this stage of a game is pendulous, swinging from a main goal to personal goals, then back to a redefined central goal. While aligning players to work towards the same goal is a common planning task, a complication that is novel to many virtual worlds is how to just make them face the same way.

Avatar Alignment and Pointing the Way

The navigation in virtual games is complicated by direction and orientation cues that impact upon planning tasks.

I'm here. I see them there. No look, right here on top of the tower; on top of their tower

For this exchange in Game B, there is a verbal planning direction to make the other characters turn around towards a distant object and face in the same direction. Lacking cardinal directions, this is so that they can align their faces and attention the same way, towards a threat posed by the opposing team, and then agree on the next course of action. Not only is the planning in a virtual world challenged by the lack of clear directions, when a virtual player lacks arms to gesture or a head to turn, then they are even further challenged to point out a particular direction when elaborating upon their plans for a particular task. There are ways of working around this.

which way do you want it to go? . . . Like that way?

For example, a player in Game A attempts to probe the physical direction of a chosen for a

small road construction by building a small section to draw the attention of other team members.

Without physically turning their Minecraft avatar, it is impossible for a virtual player to raise a hand to point in a direction for a particular planning task. They could become conspicuous and make an idea stand out in ways that are similar to we attract attention in the “real world.” A Minecraft player could make their avatar jumping, wave a sword, dig a hole, build a path to show off their actions to make their point clear and their planning task conspicuous.

To guide work on the same planning task in a virtual world with no clear cardinal directions, it is difficult for a player to ensure agreement and progress towards the same goal unless they can make fellow players face in the same direction. By facing the same challenge and problem, then the task planning dialogue can atomize a task into smaller steps that increment towards the same goal direction and the following task. It is at this point that players will exchange questions and trade their ideas.

Sharing Knowledge and Past Experience

One of Grau and Whitebread's most interesting indicative behaviors for task planning is when a person discusses his or her knowledge about strategies or personal resources that can be used in order to solve the task. There were a number of instances of players in Game B sharing strategies that they deemed to be effective. Some of these were more conventional in nature, adhering to time-tested tactics developed and refined in other games with similar modes of play, and then transported to Minecraft's version of Capture-The-Flag.

So it's a neutral game so far, I'm at imagine your spawn is just on where they're running to. It's great that spawn point.

The player shares their personal knowledge of the “great” spawn point, suggesting a level of familiarity with the layout of the map. This is interesting in that while the map is randomly generated, this player has either gained enough experience in the limited play time of this session to make a formative judgement on which “spawn

points” are the most effective, or they have identified a pattern in the algorithm that Minecraft uses to place “spawn points” when generating these maps. This dialogue illustrates how difficult it can be to make distinctions between the four broader processes within shared regulation, as this one sentence shows that the player is both monitoring and evaluating their team members. It draws on the knowledge of the other games of Capture-The-Flag to evaluate the performance of the player’s team relative to their opposition, uses this evaluation to predict the opposition next strategy, and then in the same instance uses this knowledge to inform the suggestion of a potential strategy to counteract the likely maneuverers of the opponent.

As in other virtual and online environments (Hanewald and Gesthuizen 2009), task planning is undertaken by players who seem to be trading a currency of support, thoughts, ideas, and sharing experiences. Perhaps it is not surprising that in virtual games, some players would offer to trade with their life.

Personal Sacrifice and Reputation

In the Capture-The-Flag mode, one player has a rather unique understanding of the mortality of his game avatar as a resource to be exploited in achieving the team goal:

I'll be, I'll be a body bag.

This line suggested that the player was offering to position their character as a physical shield and protect another player running towards the opposing team’s flag. To understand this perspective and planning strategy, it is important to understand that players generally view their virtual character as a respawning avatar and recyclable resource. This strategy offers a chance to boost reputation at the risk at failure. A willingness to sacrifice your individual virtual health to assist the team commands a level of creativity and innovation. It does require that the plan is accepted by the other team members.

Justifying Your Plans and Planning by Nudging

Players in a virtual world can easily be seen as being distracted or working off-task. To counter

this, they may need to articulate a modified plan that will justify their action or move that they are planning. Two examples of this occurred during Team-Build Game A when it briefly appeared that a player was briefly off-task as they were building a floor in their building and when they had found a fun feature such as a bubbles action that was worthy of distraction.

I need to make sure we get this or the ground in there would be a hot mess, okay?”

“Oh Lets see, I’m gonna go hide it back here, just in case it’s bad

When planning, players will give repeated verbal instructions to nudge another player into the correct position or a construct in a particular direction. While emphasis can be given to a planning task instruction by speaking louder or inflecting the voice, without the benefit of a visual expression or gesture, players can still give due emphasis towards their instructions by repeating them or gently prod another player into a desired location or build position.

.. a bit taller. I'll be telling just a bit though, just a little bit, just a little bit.”

“.. Please step down, one more step down

Unlike working in the real world of a classroom, laboring on a complex task in a virtual world requires more explicit instructions to help change the behavior of other players. This can wildly vary from a gentle push to move a single block to a boldly unorthodox maneuver that threatens to undermine the unity of a team or destroy the spirit of the game.

Planning Your Task Legitimacy and Morality

Game B Capture-The-Flag involved an interesting discussion about the morality, “legit” or legality of a particular game action or nuances that would advantage them. One player in this game used a particularly unusual movement across the game map by sacrificing themselves but felt it necessary to firmly articulate the details of what they were planning to other team members.

I get back to the flag faster anyways.

That's actually legit strat, you could suicide and get to the flag quicker . . .

Okay, just keep coming down.

Okay, watch out this is legit. This is like, this is serious business guys

The exact location of random spawn point where a team player reappears after their demise could provide that team a slight advantage by the novel strategy of a highly unusual but unexpected movement across the game map. Anticipating the potential for scorn from fellow team members, this player has emphasized the legitimacy of the movement, reinforcing that the advantageous movement was not restricted by any explicit game rules. In a sense, this player is using their task planning to affirm the legitimacy of the action that they are seeking and permit its adoption and use.

*Okay, I'm sneaking around seeking staircases.
I'm sneakin, I'm sneakin.
Okay I've got the flag*

For example in this dialogue from Game B, a player is similarly detailing their planned movements across a map. Many first-person shooting gamers express a disdain for players that hide their position on a map, avoid any obvious movement, then “snipe” or shoot from a distance, a behavior that is derogatively described as “camping” (Ash2x 2007). It seems to be considered more dignified to give the other team a fighting chance by encouraging moving about while you are shooting with the added skill of avoiding becoming a target. By contrast, it is considered fair game to move about the map in secret. What is interesting with this line of dialogue is that the player is attempting to explain their covert actions to verbally justify the morality of their chosen online behavior to the other team players. They are clearly engaging in a form of social regulation.

Examples of Players Motivated by Organizational Planning

The second subcategory of planning is referred to as organizational planning which involves the participants planning the organization of the task at a pragmatic level, such as allocating roles and setting expectations of individual contribution to the team. Instances of organizational planning were observed in both Game A and Game B, although these manifested in different ways. Once again, the rules of play dictated by the game design interwoven with the social norms of each respective sub-community resulted in contrasting expressions of this process, as outlined in Table 4.

Egocentric

Many statements shared in virtual environments are egocentric in the sense that they notified teammates about what a player was intending to do. Reviewing the instances of organizational planning observed in Minecraft listed in Table 4, a number of considerations become apparent from the dialogue shared in Game A.

*I think, I think I'm gonna try to do like the Krista the Krusty Krab.
I don't know if I have time I believe, but I'm gonna try*

This can be interpreted in a number of ways depending on the allocation of social capital within the group. It may be the case that this player feels inferior to their teammate, sensing that they don't have an equal level of experience and hence are in no position to dictate what their peer should be doing with their limited time. Alternatively, they may see their peer as being inept and

Shared Regulatory Planning in Minecraft, Table 4 Instances of organizational planning observed in Minecraft play

Indicative behaviors from Grau and Whitebread (2012)	Game A: Team-Build (Gamer Chad 2018)	Game B: Capture-the-Flag (Bajan Canadian 2014)
Student plans the organization of the task in a pragmatic level (who is going to do what)	“I’m gonna go and get stuff for SpongeBob’s little house.” (t = 59 s) “I think, I think I’m gonna try to do like the Krista the Krusty Krab. I don’t know if I have time I believe, but I’m gonna try” (t = 4 m 45 s)	“I’ll be the defenseman, I’m gonna post up, I’m gonna post up.” (t = 1 m 32 s) “You want to run the flag?” (t = 3 m 03 s) “I got three and got one of them at almost. Tyler, I’m just distracting. Mitch I’m just buying you time” (t = 5 m 57 s) “Yeah okay I’m through them, through big. I’m going the left side, protect my left side.” (t = 10 m 16 s)

feel that they will have to engage in most of the construction as a unilateral act if their team is going to be competitive in the Team-Build game. It is important to note that unilateral planning and action is not necessarily selfish in nature, as they can be an important process in having a team adjust an unsuccessful strategy.

Sense of Task Urgency

The examples elicited from Game B also show how the sense of urgency provoked through real-time interactions with an opposing team require more spontaneous and shorter-term planning, with less dialogue dedicated to planning for the “long game.” Instead, players were largely observed planning their response to events that had just occurred. Considerable dialogue involved adjusting their strategies in response to a defensive breakdown around protecting their flag.

I'll be the defenseman, I'm gonna post up, I'm gonna post up.

This dialogue from Game B follows the team ceding their flag to the opposition. There is a sense of urgency to this comment, with the player fearing that the opponent was nearby, and that another successful maneuver by the opposition could shift the momentum irreparably in the other team's favor. Through conveying these fears to the rest of team, the player signals a perceived need for a change in team strategy. Recognizing and communicating this recognition for adjustment is an important process within organization planning. It gives notice about continued engagement and the scope for plans to change.

Changing Task Strategy

This is a recognition that a change in strategy is required, with the need for a more defensive posture. Within the broader cycle of shared regulation, this verbalization can be seen as serving dual purposes. It is both a pragmatic allocation of human resources and perhaps more contentiously a subtle reminder to the other players of the need to play a defensive role, as opposed to prioritizing individual glory and focusing on the thrill of capturing the opponents flag. This shift in emphasis from prioritizing exhibitions of individual skill

towards planning coordinated strategies where players are willing to take on a secondary role was also seen in the team's offensive endeavors. Through subsequent cycles of attack on the enemy base, it can be heard by one player that someone else should be going for the flag while the player will protect the designated flag carrier:

You want to run the flag?

Adjusting the plans at the shared-level requires some degree of recognition from the other players that the existing plan is unlikely to succeed. The degree to which players change their actions as a result may reflect their confidence in this plan but can also be influenced by their own self interests. They are foreseeably much less likely to agree to a plan if they perceive this new course of action as disadvantaging their process towards their individual goals, such as gaining the most enemy “kills.” This is tension between individual success and group success is a recurring theme when considering organizational planning.

Unilateral Organization Within the Team

In the duress of a competitive game, players are often forced to make decisions without consulting their peers out of necessity. In Game B, for example, players in the game explained a strategy that involved a measure of self-sacrifice for the greater good of a team. In one instance, one described themselves as becoming a “body bag,” hinting at a strategy that would involve their easy death by the opposing side. Another player verbally justified their planned reckless behavior to reassure the other team members:

Tyler, I'm just distracting. Mitch I'm just buying you time

This dialogue between two attacking players shows an instance where one player has unilaterally recognized that effective planning requires more time and has decided to take matters into his own hands. Although the planning has occurred at an individual level, the player needs to share his plan with his peers to put it into action. As the first player has already begun to put this plan into action by jumping around and drawing attention from the opposition, the other players

need to evaluate the effectiveness of this plan and then either accept it or form an alternative plan. Shared planning requires a complex consideration for both individual and group goals, although as the above example shows, the social goals are ultimately filtered by interpretations of the “team goal” by individual players. Although planning at a shared-level allows for the declaration and careful consideration of every player’s individual goals, the added pressure of a time limit in Game A and an opposing team in Game B can disrupt these negotiations. This can leave players making unilateral decisions that they believe are in the best interests of the team.

Planning Roles Within the Team

As Game B progressed, the pendulum between planning pragmatic roles gear towards either individual success or team success swung back towards prioritizing the individual player. This was likely a conscience of victory for the player’s team at this late stage of the match being seemingly assured:

Yeah okay I'm through them, through big. I'm going the left side, protect my left side.

In this dialogue, the player is still planning the roles of the other players but sought to coordinate them in a manner that positioned himself as the central protagonist in the action. This position of the self as the hero through this pragmatic organization reflects both the power dynamics within the group and brings to mind questions player perception of individual identity within the group. This player wanted to be perceived by his peers as the hero, seeking to align perceptions of his individual success with the team achieving their common goal. This careful framing of socio-

emotional planning dialogue can help mitigate unwanted responses by other team members and their steer perception of the player as focused on the welfare of the team.

Examples of Players Being Motivated by Socio-emotional Planning

Finally, Grau and Whitebread suggest a third subcategory of planning entitled “socio-emotional planning.” This involves preempting what other people may feel and planning a way to avoid negative or unwanted emotional responses from peers. This is the most interesting category, as there are no examples provided by Grau and Whitebread (2012) in studying collaborative interactions in the primary Science classroom. This is where examining social regulation through the context of the lens of Minecraft becomes particularly interesting. Three instances that could be classified as socio-emotional planning were found in both Game A and Game B, as highlighted in Table 5.

Unraveling the planning process in any online game requires a measure of subjective interpretation grounded in a clear understanding about the culture within and surrounding the game. To draw a connection between planning for the emotional state of the other players and the associated dialogue requires an understanding of the social norms found within Minecraft communities and an understanding of the design of the respective modes of play. In the Game B Team-Build example, a planning instance can be classified as socio-emotional planning when one player prefaces her critique of her peer’s taste in architecture with the phrase “OK, I mean it looks really good,” preempting his foreseeable displeasure about

Shared Regulatory Planning in Minecraft, Table 5 Instances of socio-emotional planning observed in Minecraft play

Indicative behaviors from Grau and Whitebread (2012)	Game A: Team-Build (Gamer Chad 2018)	Game B: Capture-the-Flag (Bajan Canadian 2014)
None provided as Grau and Whitebread reported they did not observe any instances of socio-emotional planning	“OK, I mean it looks really good but I don’t like it. It should be 3D.” (ref here)	“You ever ate butter with a spoon, <i>that’s how it’s gonna be.</i> ” (t = 1 m 41 s) “Listen they needed that, they needed that. You don’t mean cuz they were getting really demoralized, so this is good alright” (t = 1 m 22 s)

receiving negative feedback on his plans for a particular component of SpongeBob's house. By including this phrase, she is acknowledging the emotional connection he may have developed to his work. In an arguably unrefined manner, she is trying to both praise his effort and share a critique about the product of his labors.

Maintaining a Balanced Team Mental State

Reviewing the instances of socio-emotional planning in the game of Capture-The-Flag also requires a deeper understanding of this mode of play. This mode is more intensively competitive by design, with a game being scored in real-time through a combination of enemy "kills" and flag "captures." A player and a team's relative success is broadcast to everyone playing or observing the match, with the game providing instantaneous feedback on an individual's performance for the world to see. This public sharing of an individual's contribution to the success, or lack of success, in achieving the team goal may foreseeably have a toll on their performance. Just as talk about baseball players who "get into a rut" and are seemingly unable to hit the ball, competitive gamers can falter under the glare of a public audience (Jin 2010). This can occur despite their objectively high level of playing experience and past successes. Following this logic, the other players have a vested interest in maintaining an individual player's emotional state in this more competitive environment. In Game B, this planning for a "winning" team mindset begins early, with one player predicting that:

You ever ate butter with a spoon, that's how it's gonna be.

This seemingly boastful comment, comparing the perceived "easy" level of competition from the opposing team to a hot spoon easily digging through butter can be interpreted in a number of ways. One interpretation is that the comment was designed to be reassuring, allaying the fears of his teammates and reducing the levels of anxiety about playing on an unknown, randomly generated map. This preempting of a negative emotional state is also evident when considering later dialogue after a significant individual error, which

could have had ramifications for achieving the collective goal:

Listen they needed that, they needed that. You don't mean cuz they were getting really demoralized, so this is good alright

These are the affirming words from one player to his teammate after he failed in his designated role of defending his team's flag. The player was caught unaware and was killed by an enemy player, leaving their flag vulnerable. From this event, the opposing team scored a much needed victory. The affirming player has identified that this player is most likely feeling responsible for this loss and has reminded him and the rest of his team that they still maintain a significant score advantage over the other team. All three examples are interpretations of dialogue through the lens of socio-emotional planning, with other equally valid interpretations of the dialogue being possible. What they serve to do is provoke thought about the value that players place on the emotional state of their peers, and of this may be strategically manipulated through bilateral and whole team communication.

Conclusions: Social Regulation Within Multiplayer Digital Gaming

Educational systems in developed economies are increasingly called to assist in the transition from a manufacturing-based economy to a knowledge-based economy with a priority placed on "soft skills" (Lay and Kamisah 2017) such as the set of effective collaboration skills privileged by both educational theorists and economists (Griffin McGaw and Care 2012). Central to these skills are the processes of social regulation. Grau and Whitebread's coding scheme can help identifying and classifying "real world" observations of the processes and subprocesses within regulatory planning. As a tool, it can help understand the potential motivations underpinning these processes. The provision of a common vocabulary, alongside the indicative behaviors, allows for a comparison between the frequency and nature of regulatory planning in physical spaces. This is the

basis for an improved model that better describes and defines the ways that social regulatory process can occur within simulations and virtual environments such as the Minecraft game. The model will need to consider the complex relationship between the virtual environment design, artifacts, location, and social regulation.

Pertinent questions include:

1. What are the differences between players engaging in online play and local multiplayer, and where players are co-located in a shared physical space?
2. What is the role of game design in promoting social regulation?
3. What is the relationship between people using these processes in a designed virtual environment and people using them in other contexts in the physical world?

Whether it is working together to build SpongeBob's house, designing a sustainable form of transport, or undertaking a joint experiment in a Science class, when people are working and planning together on a shared task, a refined understanding of these social regulatory processes will assist with their effective collaboration.

A dedicated coding scheme that derives from this model would allow for a nuanced study of the social regulation of cognition, emotion, and behavior in a virtual context. Not only would this be an asset in developing better games by incorporating principles that encourage positive social regulatory processes, an improved understanding of the relationship between virtual world design and its influence upon player interaction could have wider implications for the design of these virtual environments and other simulations.

Situative Perspective and Determinants of Technology Acceptance in Educational Technology

[Situative perspective](#); [Technology acceptance](#); [User motivations](#)

Technology acceptance studies in education have proliferated in recent years. As education technologies take on more prominent roles in education, it has become necessary to study the antecedent factors to students' acceptance of technology to ensure the adoption of innovative and proven education technologies. Technology acceptance is based on the observation that user motives affect acceptance of technology (Davis 1989). The field of technology acceptance aims to identify the motivational factors determining intentions and use of technology.

The technology acceptance literature is grounded in the cognitivist perspective, taking inspiration from the theory of planned behavior and the theory of reasoned action. Technology acceptance researchers have also been informed by innovation diffusion theory, social cognitive theory, and self-determination theory, among others, as they have sought to understand the

determinants of technology acceptance. Subsequent to Davis' (1989) original formulation of the Technology Acceptance Model (TAM), many extensions have been proposed, reflecting the wide ranging contexts of technology applications. More recently, attempts have been proposed to create a unified theory of technology acceptance and use (Venkatesh et al. 2003). While some have pointed to the proliferation of models as a shortcoming of technology acceptance models, others have argued that the parsimonious character of the core factors of the TAM is a strength, because it recognizes the contextual specificity of technology application situations (King and He 2006; Sun and Zhang 2006; Venkatesh et al. 2003).

The TAM is composed of five key constructs: Perceived Usefulness, Perceived Ease of Use, Attitude, Behavioral Intention, and Use. According to the TAM, the actual use of a technology is determined by the user's behavioral intention to use the technology. The user's behavioral intention is an immediate antecedent to use of the technology; whereas, the user's attitude toward the technology determines their behavioral intentions. Perceived usefulness and perceived ease of use are two fundamental antecedents posited to influence attitudes toward use. The original TAM advanced that perceived ease of use influences perceived usefulness, and perceived usefulness is also related to behavioral intentions. The TAM has garnered substantial empirical support and is one of the most widely employed models. All the core relationships, save the more questionable link from perceived ease of use to perceived usefulness, have been replicated across a wide range of contexts.

Whereas technology acceptance investigations around exogenous antecedent variables have been focused on user beliefs (Bagozzi 2007), attempts have been made to incorporate situational factors to account for the contextual specificity of technology applications as TAM has historically explained less than 50% of variance in user behavioral intentions (Venkatesh et al. 2003). To the extent that situational factors are

considered, they have been often relegated to single factors such as Subjective Norm, Voluntariness, or Facilitating Conditions (Venkatesh et al. 2003). However, the situative perspective (Greeno 2011) militates more broadly for the influence of situation on user's beliefs. In this perspective, a user's beliefs are reflexively determined through their participation in the situated activity and meanings (Gee and Green 1998), and conversely, situated meanings and activities are constituted in users' perceptions of the situation. In practice, meanings, including beliefs, are inseparable from the contexts of use. Concretely, what this suggests is that choices of technology are constrained by the situations and activities that employ the given technological tool to accomplish specific objectives. Thus, participants' choices do not operate independently and technology acceptance cannot simply be conceived as a function of user beliefs. A useful example is provided by social media technologies since the technology represents a platform for community, the affordances of the technology are reflexively determined in the dynamic interactions between individuals and collectivities. In other words, Twitter, Facebook, and Instagram offer greater affordances than any other functional replicas from a horde of copycat social media applications that offer neither the scale nor the depth and range of human contact and ingenuity provided by high levels of social adoption of the preeminent platforms. However, as the founders of these preeminent platforms recognize, the platforms depend crucially on their communities. Indeed, their value lies in the communities they have built. This inescapable duality is central to the situative perspective. In other words, technology acceptance must be conceived within the frame of activity that the technology in question enables or facilitates – its conditional affordances (e.g., usefulness, ease of use) – but where such technology is integral to the activity, such as the social media platform, we must also consider that the activity itself limits the range of acceptable choices, whether on a socio-organizational, technological, or

individual level. You may choose any social media technology from an ever-growing list of options; however, the community or activity that you wish to engage with will dictate the technology that you are required to accept. Such considerations move us beyond the scope of voluntariness, social norm, or facilitating conditions – all which have been conventionally defined with regard to individual cognitions. Increasingly, social media technologies are required for participating in many professional communities or communicating with the marketplace. In these situations, user beliefs such as perceived usefulness and perceived ease of use only provide a partial explanation of individual technology acceptance as determinants of user actions in social contexts are often grounded in social imperatives. To the extent that social participation in a community is contingent on acceptance of some technology, a user will find their choice constrained by necessity.

The situative perspective on technology acceptance holds that situational determinants operate on the whole model, that is, on the core factors and path relationships as well. In other words, according to the context of technology use, certain factors may take on more or less salience. For instance, the workplace has been shown to influence users' behavioral intentions, as employees may have little or no choice in the technology they use (Sun and Zhang 2006; Venkatesh et al. 2003). The influence of the organizational context on user's beliefs is suggestive of a class of moderating influences on technology acceptance that has not received due consideration. Whereas TAM is grounded in user beliefs, little attention has been given to the influence of the modality of these beliefs on the core TAM constructs. However, such modalities appear to interact with situational determinants to influence contexts of technology acceptance. Doleck et al. (2017a) proposed an organizational matrix, adapted from Sun and Zhang's (2006) synthesis of the literature on moderating factors on the TAM, that illustrates how moderating influences on the TAM can be conceived as resulting from the interaction of

situational and modal characteristics. Moderating influences such as voluntariness, individual/group dynamics (i.e., subjective norm), and cultural background are conceived in terms of the modality of necessity, such that a user may feel internally compelled or externally constrained to use a certain technology. Other moderating factors that may determine use as a requirement of the task, activity, or profession may be conceived in terms of the modality of certainty. For instance, where performance stability, safety, trust, or uniformity in application is a requirement of the activity (e.g., failsafe), legacy systems may be preferred even though better options may be available. Finally, technology acceptance beliefs may be classified as a function of the modality of possibility or conditionality (e.g., affordances) where the technology application is oriented to solving complex problems or fostering innovation. Such innovative uses may be witnessed in the rapid and unceasing proliferation of web programming frameworks, all proposing novel solutions and providing new extensibility to the original problem of delivering web content.

Research demonstrates that external factors exert a strong influence on core TAM constructs and are often as important if not more important sources of explained variance on both behavioral intentions towards and actual use of technology. In a series of studies exploring technology acceptance among students and general population (Doleck et al. 2017a, b; Lemay et al. 2017), factors expressing the modality of necessity were shown to strongly influence attitudes, behavioral intentions, and use of social networking, imaging sharing platforms, and online and computer-based education. In these contexts, the perceived necessity of the technology contributed large amounts of variance explained over the contribution of the conditional affordances of perceived usefulness and perceived ease of use. Thus, considering the modality of the underlying beliefs informing technology acceptance helps researchers situate technology within the frame of social activity. By helping to better conceptualize the range of constraints and affordances of

technology, the language of modality helps understand the situational determinants of technology acceptance and use.

Introduction

There are many forms of Interactive White Board Technologies (IWBT), but usually an IWBT combines an electronic touchable whiteboard connected to a network computer and a data projector. IWBT allows teachers and students control applications by touching the screen with their fingers or writing digitally with a non-ink pen tool. The touch-sensitive nature of IWBT facilitates more efficient presentation and more professional delivery of multimedia resources (Smith et al. 2005).

The IWBT or the smart board is believed to increase the effectiveness of teaching both qualitatively and quantitatively and to greatly facilitate the use and benefits of computers and the Internet for teachers (Somyürek et al. 2009). IWBT represents a tool and an environment that promotes dialogue and knowledge building among students (Warwick et al. 2010). Students can benefit from the different learning styles provided by IWBT features and software application where students could see, touch, and hear the content of the lesson. Therefore, IWBT promises to elevate teaching to new heights and represents a key enabler for the creation of student-centered

Skills

► Teaching with Computing, Educational Games

collaborative environments (Somyürek et al. 2009) and hence could foster performance parity and increase student achievement (López 2009). Similarly, IWBT is considered an effective interactive learning approach and is being used in teaching and grading and expected to alter current pedagogical system and means of exchanging information with students (Stoica et al. 2011). For teachers, the IWBT made their lessons more enjoyable, and for students, the IWBT resembled an opportunity to actively participate in a lesson and to internalize inputs in a more appropriate manner (Gursul and Tozmaz 2010).

However, upon a thorough consideration of IWBT literature, it was observed that many challenges surround the successful adoption and usage of this technology. Slay et al. (2008) found the IWBT research divided into two areas: investigate the use of IWBT in particular subject areas and solicit teachers' and learners' perspectives on the IWBT technology. At the outset, although integrating technology into teaching and learning is growing, non-anecdotal evidence of IWBT effectiveness in teaching and how to implement a successful IWBT classroom is lacking (López 2009) and even controversial (Gursul and Tozmaz 2010). For example, Warwick et al. (2010) found existing IWBT research focusing mainly on teacher–pupil interaction and ignored pupils' collaborative needs. On the other hand, other researchers noted that existing IWBT research focused on the effective use of IWBT in the classroom and its impact on student's academic achievement and largely ignored teachers' opinions about IWBT (Gursul and Tozmaz 2010). This scant research (Somyürek et al. 2009) reported limited successes with IWBT and failed to clearly state the problems and solutions and the successful implementation of IWBT in teaching (López 2009).

In looking at some adopted approaches, Warwick et al. (2010) noted that the introduction of new technologies in teaching did not address its link to pedagogy as such. This is aggravated by the attempt to introduce new innovations like the IWBT into old educational models (Warwick et al. 2010). Korucu et al. (2011) even questioned

whether teachers are capable of using IWBT or not.

Therefore, it is not surprising that researchers like Lopez (2009) asserted that innovative technologies like the IWBT must be introduced as a disruptive innovation, where it should not compete with existing current curriculum and instructional practices but rather to challenge the teachers' ability to discover new features in IWBT and use them to devise new ways of teaching. Accordingly, educators should develop accurate plans and strategies to integrate technology into teaching as educators may lack a clear understanding of the pedagogical principles underlying integrating these new technologies in the classroom (Salinas 2006; Somyürek et al. 2009). For example, Stoica et al. (2011) highlighted the importance of addressing student's cognitive capacity and limit and that teachers must always be alert about their objectives and in identifying appropriate content and assessment techniques. They indicated that students working in teams are more inspired and more excited where, for example, with the aid of the IWBT, collaborative students could intricate their conceptual micro-maps more effectively.

Interactive White Board

Korucu et al. (2011) shed more light into teacher's perceptions toward IWBT usage and reported that teachers agreed on the positive impact of interactive materials in the classroom despite its scarcity and limited use in the classroom. Teachers reported difficulty in using IWBT and interactive materials (including visual and animation content) and in creating it. The same researchers found that although most teachers raised the importance of having IWBT in all classrooms, they did not prefer using interactive material and viewed IWBT as not to have a positive effect on the courses they teach.

This confusion in IWBT research and in appraising the outcomes of IWBT could be attributed to the lack of knowledge about the effective use of IWBT in the classroom. Teachers with

limited knowledge in technology would refrain from using the IWBT because portable IWBT requires adjusting its calibration settings, more frequently (Gursul and Tozmaz 2010). In the same vein, Korucu et al. (2011) contended that it is essential to strike a match between teachers and IWBT capabilities for IWBT to succeed in education which could be bridged by in-service training. Gursul and Tozmaz (2010) contended that once IWBT is integrated correctly into the curriculum and this process is continuously employed, the IWBT could prove to be a revolutionary invention for schools. To elevate the argument further, Warwick et al. (2010) concluded that technology alone cannot change classroom teaching and learning but rather requires mediation by the teacher. Hence, the teacher role is not confined to direct intervention which will scatter pupil interaction at the IWB but to developing innovative ways which employ his/her pedagogical knowledge to come up with appropriate learning tasks.

Student's use of IWBT is also limited. For example, Gursul and Tozmaz (2010) found that the activities carried out by students on IWBTs were limited to using it for normal board activities (solving questions, writing, etc.) (29%), and explaining things which would otherwise be impossible to do so in classrooms through animation (23%). They reported scant use of the IWBT in carrying out interactive activities such as matching, dragging, and painting; permission to control the computer; and making children play games related to the subject of a lesson.

IWBT provides many benefits to teaching, such as offering flexibility, versatility, multimedia ability, efficiency, interactivity, lesson participation, collaboration, idea sharing, motivation, instant access to vast electronic resources, and the ability to save and post drawings and writings on the board (Slay et al. 2008; Smith et al. 2005). Lopez (2009) found that digital learning classroom promotes positive social norms and a learner-centered pedagogy where both teacher and students are learners, which allows for the development of common themes and shared meanings. Teachers began sharing their direct instruction with the IWBT and students

interacted with the IWBT when they were prompted by the lesson unit. Smith et al. (2005) highlighted that teacher-student interactivity is the primary benefit of the IWBT. Slay et al. (2008) reported the following advantages from a teacher's perspective:

- a. Seamlessly access one resource after another from the board
- b. Allow teachers to support multiple needs within one lesson
- c. To draw from countless multimedia sources
- d. Ability to face the class while teaching which allows teachers to maintain class control
- e. To be more in touch with the learners by maintaining eye contact than when using a laptop and from a learner's perspective:
- f. Saw IWBT as effective tools for initiating and facilitating the learning process, in particular when they were given the opportunity to use the IWBT themselves
- g. The visual nature of the IWBT allows for different ways to presented information which reinforce concentration and attention
- h. Learners pointed to their teacher's lack of ICT skills, associated cost of IWBT technologies, and the technical reliability of the IWBT as disadvantages of the technology

Slay et al. (2008) highlighted six factors that were consistently reported by the literature to influence teachers' and learners' use of the IWBT and reported the following theoretical implications:

- a. Improved visibility of classroom content
- b. Value of multimedia content (audio/videos, online/offline content, etc.)
- c. Motivational use of up-to-date technology where the contradictions here are twofold
- d. Interactive affordances
- e. Lack of ICT literacy and competency
- f. Cost

In the same vein, Somyürek et al. (2009) found teachers, though not having a negative attitude toward ICT, reporting the following reasons for the limited use of IWBT:

- a. Lack of technical competency on how to use IWBT
- b. Lack of pedagogical competency on how to integrate them into classroom activities
- c. Lack of a school plan on the use of IWBTs
- d. Lack of both technical and pedagogical in-service trainings and how to integrate IWBT into the learning processes
- e. Lack (number and quality) of digital educational materials to highlight the advantages of multimedia, including static and dynamic images, sounds, videos, animations, web sites, presentations, and text editors
- f. Lack of support and maintenance
- g. Administrative concerns: lack of measures to monitor the use of IWBT and the failure of school administrations to encourage teachers use the IWBTs, scheduling of ICT installed classrooms, and sharing of digital educational materials among the teachers

Schmid (2008) addressed the notion of effective multimedia integration in IWBT-based classroom and reported the following:

- a. Advantages: Use of multimedia in IWBT-based classroom facilitates students' learning processes
- b. Challenges: teachers and learners faced in the process of multimedia integration

Table 1 shows a thorough examination of these factors alongside four main themes: advantages, complexities, management support, and compatibilities. This table also shows the questionnaire development criteria which is explained next.

Case Study

UAE University (UAEU) is the first national (federal) university in UAE. It was established in 1976. The university's founding mission was to realize the aspirations of the society, deepen social ambitions, and consolidate the structural foundations. As of 2011, the UAEU has over 12,000 students, primarily based in Al Ain city. UAEU has over 650 teaching-faculty members and offers

bachelor degrees, postgraduate courses, PhD programs, and continuing education programs for the community at large.

Data for the study was collected in 2011 by means of a survey questionnaire based on the research model in Table 1. Standard measures were used (where available) during the design of the measures adopted in this study. Some of the previously validated measures had to be adapted to meet the constraints of this questionnaire. Table 1 shows the development of the different research variables in the research model and their measures. On a scale of five-point Likert scale (1 = Strongly disagree, 5 = Strongly agree), respondents were asked to provide their opinion about the different characteristics of the IWBT in relation to teaching in the classroom.

Before the questionnaire was emailed out, it went through extensive pretesting with teaching-faculty members. Particular attention was given to wording, structure, sequence, and overall presentation of the items in the questionnaire. The questionnaire was pilot-tested with 15 teachers. Interviews were conducted with those teachers to determine whether there was any problem with the questionnaire questions or format. On the basis of their comments, changes were made to the questionnaire to clarify wordings and increase readability. Four teaching-faculty members further revised the final version. The pre-testing procedure is important to establish content validity. Responses from the piloted teachers were not included in the survey.

An online version of the survey was created and posted on the university's web site targeting all teaching-faculty and instructors. Two hundred and twenty-eight responses were received. The effective response rate was 35.1%. The questionnaires were coded and keyed into the SPSS statistical software tool. The following tables show statistical details about the sample and IWBT.

When asked whether teaching-faculty adopt or not adopt IWBT, 93% were found adopters and 7% did not adopt IWBT (Table 2). Usage as a measure provided more accurate depiction of IWBT penetration in UAEU. As can be seen from Table 2, the majority of surveyed teaching-

Smart Board Technology in Higher Education Institutions, Table 1 Theoretical IWBT adoption framework

#	Item	Source
	Advantages	Adapted/extended
	IWBT better relieves physical fatigue IWBT enhances the preparation and the management of my class IWBT offers better features	Baek et al. (2008)
	IWBT offers more visualized content (graphics, colors, web sites, etc.) (Schmid 2008; Slay et al. 2008; Smith et al. 2005) IWBT provides better exercises and assessments IWBT provides more variety of teaching methods (Slay et al. 2008; Smith et al. 2005) IWBT provides easy access to different resources at the same time in the classroom (newly introduced) IWBT allows the instructor to satisfy multiple learning needs within the one lesson (newly introduced) Using the IWBT in the classroom increases instructor-to-student interactions (Slay et al. 2008) Using the IWBT in the classroom increases student-to-student interactions Using the IWBT's different resources enhances the student's conceptual understanding Using the IWBT's different resources in the classroom enhances the student's practical understanding (newly introduced)	Barak (2007)
	IWBT offers more flexibility IWBT provides better lesson participation from students IWBT provides better collaboration between students (also adapted from Schmid 2008) IWBT enhances idea sharing in the classroom Ability to save and post drawings and writings on the board I save notes made on the IWBT for later use by me or students I post (e.g., email) saved notes made on the IWBT to students	Slay et al. (2008), Smith et al. (2005)
	IWBT in the classroom promotes positive social norms and habits IWBT promotes learner-centered teaching	Lopez (2009)
	IWBT enhances the facilitation of learning IWBT in the classroom saves the instructor's time Compared with earlier practices and technologies, the IWBT gives me more time to face the class (also from Slay et al. 2008)	Schmid (2008)
	Complexity	
	IWBT fails more frequently during the class session (also from Slay et al. 2008) IWBT faces more hardware problems in the classroom (also from Somyürek et al. 2009) IWBT faces more software problems in the classroom (also from Somyürek et al. 2009) IWBT takes longer time to repair (newly introduced) IWBT requires more specialized technical expertise to fix it (newly introduced) Learning about the different information technology resources for me in the classroom is difficult for me (newly introduced)	Baek et al. (2008)
	Lack of technical competency on how to use IWBT Using the IWBT in the classroom is easier for me (newly introduced) Integrating course-content with the IWBT is an easy task for me Lack of digital educational materials to highlight the advantages of using the IWBT in the classroom Lack of support and maintenance limits my ability of using of the IWBT in the classroom Virus problems cause the IWBT to run inefficiently	Somyürek et al. (2009)

(continued)

Smart Board Technology in Higher Education Institutions, Table 1 (continued)

#	Item	Source
	Management support	
	The university/teaching-faculty have a clear plan for the effective use of the IWBT in the classroom The university/teaching-faculty provide sufficient technical training on how to integrate the IWBT technology into the teaching processes The university/teaching-faculty provide sufficient teaching trainings on how to use the IWBT for teaching The management puts measures and procedures for the effective use of the IWBT in the classroom The management supports the effective use of the IWBT in the classroom (newly introduced) The management is involved in the effective use of the IWBT in the classroom (newly introduced) The management leads the effective use of the IWBT in the classroom (newly introduced)	Somyürek et al. (2009)
	Compatibility	
	IWBT features are suitable to the course content that I teach in the classroom (newly introduced)	
	Have enough time to use the different features of the IWBT in the classroom (also from Barak 2007) Have enough time to fix problems with the IWBT during the class session (also from Barak 2007) Have enough time to call a technician to fix a problem with the IWBT during the class session (also from Barak 2007) The IWBT fits with the way I like to teach in the classroom (newly introduced) I am just using the basic functions of the IWBT in the classroom Using the IWBT in the classroom could result in losing personal contacts with students (also from Barak 2007) I feel that I must use the IWBT in my teaching Using the IWBT in the classroom attracts positive attention to me	Baek et al. (2008)
	I am motivated to use the IWBT in the classroom Using the IWBT in the classroom motivates my students to learn (newly introduced) The IWBT allows me to face the class while teaching which allows me to maintain class control The IWBT allows me to be more in touch with students by maintaining eye contact	Slay et al. (2008)
	I am comfortable dealing with the different multimedia resources accessed by the IWBT Using the IWBT in the classroom limits the student's ability to practice other learning activities during the class I feel that using the IWBT in the classroom limits the exercise of other teaching methods and styles	Schmid (2008)
	I am comfortable with the way the IWBT equipment is installed inside the classroom	Somyürek et al. (2009)

S

Smart Board Technology in Higher Education Institutions, Table 2 Adoption versus usage

Adopt IWBT	Freq.	%	Using IWBT	Freq.	%
Yes	212	93.0	I do not use the IWBT	16	7.0
No	16	7.0	I use the IWBT occasionally or sometimes	48	21.1
			Using the IWBT frequently	164	71.9
Total	228	100.0	Total	228	100.0

Smart Board Technology in Higher Education Institutions, Table 3 Demographics data about teaching-faculty

Education level (highest degree)	Freq.	%	Original nationality	Freq.	%	Own laptop	Freq.	%	Gender	Freq.	%
Diploma	1	0.4	Emirati	29	12.7	Yes	224	98.2	Male	183	80.3
Bachelors	4	1.8	Other Arabs	130	57.0	No	4	1.8	Female	45	19.7

faculty were frequent users of IWBT. This is an indication of the large-scale diffusion of the IWBT in the UAEU as there is no other alternative to the IWBT in the classrooms. Interestingly, 7% of the teaching-faculty did not use the IWBT and 21% reported using the IWBT occasionally. This finding could be attributed to the fact that not all the classrooms were furnished with IWBT or such teaching-faculty did not use any illustration tool or saw limited uses of the IWBT in delivering their courses or they did not seize the full potential of the IWBT. These are interesting propositions and worth further investigation.

The average age of the surveyed teachers is 44.5 years. On average they have been working in UAEU for 1.7 years. The majority of respondents to the survey were male (80%) and holders of PhD followed by master's degree (Table 3). The majority of ethnicities in the sample came from Arab countries followed by westerners and Emiratis respectively. Almost all respondents owned a laptop. However, the UAEU contributes to this result as it grants laptops to teaching-faculty in certain faculties (i.e., engineering, science, information technology). Teaching-faculty representation in the sample came largely from the teaching-faculty of science (26%) followed by the teaching-faculty of humanities (18%) and followed equally by both the teaching-faculty of business and economics and the teaching-faculty of engineering (16%). The following section highlights the research findings.

Interactive White Board Adoption

The research analyses followed an approach that classified the research findings according to respondents' ranking of the different items where results were discussed in the light of the highly (strongly agree) and poorly ranked (strongly disagree) measures. It is worth noting here that most responses were not extreme in the sense they were concentrated around the neutral position (between 2 and 4 Likert scale), and hence, most responses did not highly agree nor highly disagree with the different impacts of the IWBT in teaching in UAEU.

If we look at IWBT advantages, the findings are split into two parts. Table 4 shows the different characteristics that were highly ranked by respondents. Those advantages ranged from aspects relating to IWBT's features (visualized content, easy access to different resources at the same time, etc.) to aspects relating to the effectiveness of using IWBT in the classroom in UAEU (enhances the facilitation of learning, enhance the student's conceptual and practical understanding, etc.).

The second part (Table 5) shows the different characteristics that were ranked lower by respondents indicating having a lower impact on their IWBT teaching. It is observed that most of the measures in the table focused on assessing the IWBT as it is integrated with pedagogy and course content. Respondents did not feel strongly regarding such aspects. Interestingly, using the IWBT in

Smart Board Technology in Higher Education Institutions, Table 4 Higher-ranked advantages

#	Relative advantage	Mean	Std. deviation
Relating to IWBT's specifics			
1	Using the IWBT in the classroom offers more visualized content (graphics, colors, web sites, etc.)	3.61	1.188
2	The IWBT provides easy access to different resources at the same time in the classroom	3.50	1.140
3	The IWBT offers better features	3.48	1.159
4	The IWBT offers a better variety of teaching methods	3.36	1.120
5	Using the IWBT in the classroom offers more flexibility	3.26	1.245
IWBT's effectiveness in the class			
6	The IWBT allows the instructor to satisfy multiple learning needs within the one lesson	3.21	1.144
7	Using the IWBT in the classroom enhances the facilitation of learning	3.15	1.136
8	The IWBT enhances the preparation and the management of my class	3.13	1.129
9	Using the IWBT's different resources in the classroom enhance the student's conceptual understanding	3.05	1.145
10	Using the IWBT's different resources in the classroom enhance the student's practical understanding	3.01	1.124
11	The IWBT better relieves physical fatigue relating to teaching in the class	3.01	1.176

Smart Board Technology in Higher Education Institutions, Table 5 Low-ranked advantages

#	Low-ranked advantages	Mean	Std. deviation
1	The IWBT in the classroom provides better exercises and assessments	2.97	1.102
2	Using the IWBT in the classroom promotes learner-centered teaching	2.92	1.017
3	Using the IWBT in the classroom enhances idea sharing in the classroom	2.86	1.064
4	Using the IWBT in the classroom saves the instructor's time	2.86	1.361
5	Using the IWBT in the classroom increases instructor-to-student interactions	2.85	1.128
	Using the IWBT in the classroom provides better lesson participation from students	2.85	1.128
6	The IWBT gives me more time to face the class	2.83	1.286
7	I save notes made on the IWBT board for later use by me or students	2.79	1.149
8	Using the IWBT in the classroom promote positive social norms and habits	2.73	0.990
9	Using the IWBT in the classroom provide better collaboration between students	2.70	1.037
10	I post (e.g., email) saved notes made on the IWBT board to students	2.69	1.112
11	Using the IWBT in the classroom increases student-to-student interactions	2.63	1.043

the classroom did not seem to save the instructors' time or to give them more time to face the class.

As for IWBT challenges, Table 6 shows different challenges confronted by teaching-faculty inside the classroom. It is clear from the responses that teaching-faculty faced several technical difficulties in dealing with IWBT's software and hardware problems which require more specialized technical expertise to fix it. They reported that the IWBT fails more frequently during the class session and it takes longer time to repair. This is further compounded by the lack of support and maintenance for IWBT which limits their ability

to use the IWBT in the classroom. However, computer viruses did not seem to be a problem for IWBT usage in the classroom.

Interestingly, teaching-faculty noted that using and integrating course content with the IWBT in the classroom is an easy task for them. Also, they did not see learning about the different information technology resources in the classroom as difficult for them. However, given the above discussion, it was obvious that the IWBT here relates to using IWBT's obvious features only, i.e., as a projector, showing a web site, etc. The lack of digital educational materials to show the effective

Smart Board Technology in Higher Education Institutions, Table 6 IWBT challenges

#	IWBT challenges	Mean	Std. deviation
Higher rankings			
Technical problems			
1	The IWBT faces more software problems in the classroom	3.86	1.008
2	The IWBT requires more specialized technical expertise to fix it	3.82	1.000
3	The IWBT faces more hardware problems in the classroom	3.82	1.007
4	The IWBT takes longer time to repair	3.76	0.992
5	The IWBT fails more frequently during the class session	3.75	1.076
2	I would call a technician to fix a problem with the IWBT during the class session	3.54	1.080
6	The lack of support and maintenance limits my ability to use the IWBT in the classroom	3.29	1.071
IWBT usage and instructions			
1	I am using the basic functions of the IWBT in the classroom	3.77	0.835
2	Integrating my course content with the IWBT in the classroom is an easy task for me	3.38	1.010
8	There is a lack of digital educational materials to highlight the advantages of using the IWBT in the classroom	3.33	0.935
9	Using the IWBT in the classroom is easier for me	3.31	1.055
Lower rankings			
1	Computer viruses represent a problem for IWBT usage in the classroom	2.91	0.920
2	Learning about the different information technology resources for me in the classroom is difficult for me	2.32	1.032
16	I have enough time to fix problems with the IWBT during the class session	2.28	1.057

use of the IWBT in the classroom further endorses this opinion. Also, it could be used to justify the low usage of the advanced features of the IWBT by UAEU's teaching-faculty.

Using IWBT is a must in UAEU as there is no alternate technology in the classrooms. Table 7 shows some positive attitude toward IWBT among teaching-faculty. They are motivated to use the IWBT and its different multimedia resources, and they felt that IWBT fits with the way they teach. However, teaching-faculty noted slight drawback on IWBT usage such as in limiting their ability to exercise other teaching methods and styles inside the classroom, and this in turn deprived students from witnessing alternative styles. In this regard, teaching-faculty seemed to be confined to using IWBT's features only. Toward the low-ranked items, there was a weak support for the impact of the IWBT among teaching-faculty. Teaching-faculty barely agreed on having enough time to use IWBT's features in the classroom and that such features are more suitable to the course content that they teach in

the classroom. However, they did not foresee the IWBT to:

- a. Attract positive attention to them
- b. Motivate students to learn
- c. Be comfortable to them in terms of its position inside the classroom
- d. Effect personal contacts with students
- e. Allow for more time to face the class while teaching which allows them to maintain class control
- f. Give more time to be in touch with students by maintaining eye contact

In looking at the supporting environment, most of the factors in Table 8 seemed not to be supported in the case of the UAEU. Although some support was provided by management and in providing training on how to integrate the IWBT technology into the teaching processes, none of the remaining factors elevated beyond the cut-off (neutral) point. Those factors need to be addressed by UAEU management in order to realize IWBT advantages.

Smart Board Technology in Higher Education Institutions, Table 7 Teaching-faculty attitude toward IWBT

#		Mean	Std. deviation

6	The university/teaching-faculty have a clear plan for the effective use of the IWBT in the classroom	2.94	0.998
7	The management puts measures and procedures for the effective use of the IWBT in the classroom	2.89	0.898

Interactive White Board Implications

The research findings were in line with the literature. For example, Gursul and Tozmaz (2010) found modest (23%) use of IWBT in the classroom by teachers who reported using the IWBT as a combination of computer and projection; carrying out such interactive activities as matching, dragging, and painting; and using it for normal board activities (solving questions, writing, etc.).

Other advanced uses of IWBT were minimally reported by the same teachers.

IWBT is considered a disruptive technology as its full realization is dependent on its full integration in pedagogy. That is, pedagogy should drive IWBT not the opposite. In reality this represents a challenge for most educators in the world. This was evident in this research analyses and the challenges faced in interpreting the research results. Due to the lack of knowledge about the effective

use of IWBT and how to integrate it in teaching, the majority of responses were concentrated around the neutral level. The lack of support for the different factors in the research framework suggested the lack of IWBT integration in teaching in UAEU. Contradicting findings in this research further endorsed this posture. Conducting longitudinal research could monitor the progress on the impact of the different factors in this research on IWBT success.

However, this research was delimited to the specified factors in this research. This research used standard measures where possible in developing the survey questionnaire. Further, most of IT research looked at adoption as a proxy for IT success. However, attempting to capture the depth of the adoption criteria of IT or its use in business through dichotomous adoption (yes/no) measures is inconclusive. This research introduced both adoption and usage measures to assess the depth of IWBT penetration in pedagogy in UAEU. It is obvious that “usage” as a measure produces more effective results here as mere adoption is not an effective indication of IWBT success. Researchers could capitalize on this research’s framework and measures by adding further factors and measures which could shed more light into the IWBT phenomenon in tertiary teaching in UAEU and elsewhere.

If we look at IWBT advantages, the implications here are twofold. First, teaching-faculty commended IWBT’s most obvious and direct advantages only which represented an extension to existing technologies in the classrooms. In this regard, the IWBT represents a superior technology with its dual smart-boards and projectors, touchable screen, and integration with a computer and Internet to display online content. However, this admiration started to dwindle as the unique and more advanced aspects of the IWBT started to emerge. This finding led to a conclusion that IWBT is not yet integrated in teaching as such in UAEU. This conjuncture could be further endorsed by the finding that using the IWBT in the classroom did not promote positive social norms and habits. Also, the lack of digital educational materials to show the effective use of the IWBT in the classroom further endorses this opinion. Reasons for such attitudes and low-usage

could be attributed to lack of knowledge and resources on how to integrate and use IWBT’s advanced features to:

- a. Provide exercises and assessments
- b. Promote learner-centered teaching
- c. Promote idea sharing in the classroom
- d. Increase instructor-to-student interactions
- e. Increase student-to-student interactions
- f. Encourage lesson participation from students
- g. Provide better collaboration between students
- h. Integrate IWBT’s notes-taking into the course content

From the above remarks it is obvious that the process with IWBT is not that easy in UAEU as it requires the collaboration of technologists, educators, and students to fulfill such integrated tasks. One possible solution here is to form a committee that includes the above stakeholders to integrate IWBT’s features and curricula. Students’ involvement is important as they are the end recipients of such integration and their acceptance and satisfaction of the developed solution is essential.

To better illustrate the above insights, Fig. 1 shows the evolution of the data-show technology across time showing the position and the strength of IWBT as compared to existing technologies in the classroom. The figure also shows the direction of the industry trends and teaching strategy along with a depiction of the learning needs across each evolutionary phase. In this research it is suggested that UAEU is positioned in the middle of the evolutionary path in Fig. 1.

Technical mishaps that surrounded the IWBT in the classroom represent a great challenge for teachers wanting to finish their classes and course material on time. The implications here are three-fold. Initially, the IWBT is maturing and manufacturers are enhancing its features, reliability, and availability in the classroom. This is an important priority. Gursul and Tozmaz (2010) suggestions toward a more efficient use of IWBTs indicated that technical staff should be available in order to overcome technical problems.

Secondly, teachers must be trained at least to address most impending IWBT’s technical problems that may arise (impede) during a class session. The availability of technical staff on-site is

Smart Board Technology in Higher Education Institutions, Fig. 1 Evolution of the data-show industry across time

important to maintain the continued functionality of the IWBT inside the classroom. A better service level agreement (SLA) with vendors should guarantee effective on-site and off-site response and repair time and putting contingency measures and backup plans, in case a prolonged time is needed to fix a faulty IWBT or server (i.e., providing a backup or portable unit). Let's not forget that the installed IWBT in each class in UAEU has dual white boards and projectors which add some redundancy and class continuity in case of a failure.

The positive teaching-faculty's attitude toward IWBT represents a good starting point which should not be missed out by management. Gursul and Tozmaz (2010) suggested that corresponding authorities should provide digital educational materials that can be used on IWBT and qualified staff to help teachers use the IWBT more effectively and IWBT should be integrated into teachers' lesson plans. This has led to the research's third implication. The adoption and diffusion of IWBT in teaching in UAEU should not be automatic rather infused in a piece-meal fashion where it should supplement exciting

teaching preferences, approaches, tools and strategies first. Teaching-faculty noted that the IWBT deprived them from exercising other teaching methods and styles inside the classroom and this would reflect negatively on students. They also noted that they did not foresee the IWBT to be an effective management and control tool inside the class. Remedying such challenges is important before elevating to the next level. Here, plans for supplanting existing teaching approaches with IWBT should be drafted in the longer term projections alongside important behavioral aspects as highlighted in this research. This entails addressing cultural perspectives concerning teaching-faculty and students. Finally, IWBT usage by teachers should be monitored to report progress.

Snap! Programming System

Bernat Romagosa i Carrasquer
Snap! team, Barcelona, Spain

Introduction

Snap! was developed by Jens Mönig and Brian Harvey under the umbrella of the University of California at Berkeley, with the objective of bringing the power of the Scheme programming

language and its computer science concepts into a Scratch-like environment. In fact, for a bunch of years, Snap! was developed as a modified version of Scratch. The ability to construct your own blocks out of other blocks was one of the foundational principles of this modification of Scratch, which is why, initially, they named it BYOB (standing for Build Your Own Blocks). In Snap!, blocks built by the user bear the same weight as any other preexisting ones. In other words, Snap! lets us build custom expressions that look and behave like primitive ones.

Nowadays, Snap! is a separate project with a codebase that is completely independent from Scratch and with an outstanding number of new features and particularities that make it suitable for a serious study of computer science as well as for research projects. However, Snap! still keeps intact everything that Scratch is about, and, in a programming language jargon style, we could very well call it a dialect of the latter.

So, before diving into what makes Snap! special, let us see what it inherits from Scratch and how it can be used for a playful introduction to programming and computer science.

What's Scratch-Like in Snap!

The User Interface

In the Snap! user interface, we quickly recognize three major column-shaped areas that resemble those in Scratch. The leftmost one is called the *palette*, and that is where we can find all the primitive expressions, in the shape of blocks. To build our programs, we will be dragging these blocks into the big, central area. This striped gray blank space at the center is called the *scripting area*, and it is where we combine these blocks together to give behavior to objects in the system.

Like in Scratch, this central column features three different tabs. Aside from the default one that we have just described, labeled *Scripts*, we can also choose between *Costumes* and *Sounds*. These two additional tabs let us deal with images that our objects can “wear” as costumes or sounds that our objects can play.

The third column is a very important one, and it is, in turn, divided into two rows. The white rectangle at the top right is what we call the *Stage*: a programmable microworld where our objects interact with each other (and with us) according to the code we have composed for them. When you first open the Snap! editor, the Stage only contains one arrowhead-shaped object, in homage to Logo, where the programmable *Turtle* was also represented as an arrow. We call these objects *sprites*, and we can see how many of them there are, what their names are, and a small thumbnail previewing what they look like at the bottom of the Stage, in an area we call the *corral*. At the center left of the corral, we can see a thumbnail of the Stage itself that can also be programmed.

Live, Parallel Blocks

Some block-based environments translate graphical blocks into text-based languages that are then fed into an interpreter or compiler. In that sense, these environments do not constitute actual programming languages but graphical, block-based façades for existing text-based languages. In such environments, we very often have to begin our programs with a predefined “start” block and run them by using some kind of “run” button or instruction.

One of the essential differences between these block-based language representations and Scratch (and thus) is that the latter does not translate blocks into any other language. Scratch and Snap! are full-fledged languages all by themselves, with an evaluator that actually looks up the graphical blocks and runs them in place.

This lets us build programs that have multiple start points and even run arbitrary pieces of code (block stacks) at our own will, whenever we want to. Clicking on a block or block stack will run it immediately, and if that block is meant to return a value, it will actually pop up a speech bubble showing that value. Scratch and Snap! are live also in the sense that we can modify code while it runs, without having to stop our scripts and restart them again to see these changes take effect.

Another key particularity of these languages lies in their parallel execution model, allowing us to run many processes at the same time. The evaluator

takes care of scheduling the execution of these processes for us and makes sure that – in the vast majority of the cases – we do not have to worry about race conditions, deadlocks, or any other quirks of concurrent programming.

Events

As explained in the previous subsection, processes can be started by just clicking on blocks and block stacks, and it is strongly encouraged to play with the language in that way, as it allows the programmer to experiment with code in an interactive way. However, sometimes we are going to need scripts to be triggered automatically upon given conditions, not just when we decide to click on them.

In languages like Scratch or Snap!, the way to bind scripts to events is to crown them with what we call a *hat block*. What these hat blocks do is to start whatever script is attached to them when the event in question occurs.

Examples of such events include pressing a key, moving the mouse, clicking on an object, receiving a broadcast message, or pressing a particular button in the user interface. Additionally, in Snap! we also have a generic “when” hat block that lets us define arbitrary trigger conditions for a script.

What Sets Snap! Apart from Scratch

First-Class Heterogeneous Lists

Snap! takes from the Scheme programming language the idea of first-class lists as the only necessary complex data structure, out of which we can build any other data structure that we can imagine. When we say that something is first class, we mean that it can be used in the same way as any of the primitive data types in the system, such as a number or a string. This implies that, in Snap!, we can use lists as if they were, for example, numbers.

As such, we can assign lists to variables, use them as parameters to blocks, have functions return them, or broadcast and receive them as messages.

Since lists are first class, and since something that is first class can be used as if it was a simple

Snap! Programming System, Fig. 1 An example of a binary tree implementation. Top: definition of the branch and root accessor blocks. Bottom: example usage with a tree list

number, it must be possible to have lists contain other lists. In fact, by embedding lists inside of other lists is how we can compose any imaginable data type.

In order for this to work, though, we also need the language to let us store whatever we want into lists, be it a number, a string, another list, a block, or a sprite. That is, lists should be able to hold anything that the system exposes as first class. Not only that, but we need lists to be heterogeneous, meaning that we need to be able to store different data types all mixed together as elements of the same list.

Having these properties we could, for instance, implement binary trees as lists where the first element holds the left branch of each node, the second element holds the root, and the third element holds the right branch (Fig. 1).

To make the tree structure easier to understand, we could build a block that hides away the internal list representation. Thanks to Snap!’s support for unicode characters and line breaks in block labels, we could even build a block that resembles a tree branch (Fig. 2).

Similarly, a stack could be implemented as a list where we can only either add a new element or retrieve (and remove) the latest element added (Fig. 3).

Associations can be thought of as lists where the first element is the key and the second element is the value, and thus dictionaries can be thought of as lists of associations (Fig. 4).

In a similar fashion, by just grouping elements into lists and building custom blocks that abstract

Snap! Programming System, Fig. 2 A more visually appealing tree representation. Top: definition of the tree block. Bottom: example usage

away the complexity of these structures, we can implement any other data structure, be it a heap, a hash table, or a set (Fig. 5).

Tables

Snap! offers two different visual representations of lists. The first one is box-shaped and displays all items contained in the list sequentially from top to bottom. This representation reflects changes to the list contents in real time, making it very useful for live inspection of objects and data structures (Fig. 6).

The second representation is the default one for lists of lists where the first inner lists have more

Snap! Programming System, Fig. 3 A possible stack implementation. Top: definition of the push and pop blocks. Bottom: creating and filling a stack with some elements and popping the last one

Snap! Programming System, Fig. 6 Traditional list representation

than two items. This representation is not live, so changes to the original objects are not reflected in real time, but it is extremely fast and is capable of displaying hundreds of thousands of rows with almost no performance penalty, which makes it suitable for inspecting big data sets and very long collections (Fig. 7).

First-Class Procedures

One of the main foundational ideas behind Snap! is to let the programmer extend the system by

building blocks that look and behave exactly like the ones provided by default. We have already seen examples of new block definitions in the previous section, when implementing different data structures, but we have not explained them in detail.

To create a new block in Snap!, we need to either head to the *Variables* category and click on the *Make a block* button or right click (command-click on MacOSX) anywhere in the scripting pane and select *Make a block* from the contextual menu.

Snap! Programming System, Fig. 7 Tabular representation of a huge list of 51.096 rows where each row is a list containing three numbers

This will open a dialog where we will be asked to select a category and give a name to the new block. Additionally, we will be able to choose among three different kinds of blocks, namely, commands, reporters, or predicates.

Command blocks are the ones that can be stacked to other blocks. They are called commands because they perform an action. Reporters, on the other hand, are blocks that can be embedded into input slots of other blocks, and they return values. Predicates are a particular case of reporters, in particular the kind that returns a Boolean value.

As an example, we will be creating a new block that draws a cross, and we will place it under the *Pen* category. Since this block performs an action, it will be a command block, and since we want every sprite in the project to be able to run it, we will select *for all sprites* (Fig. 8).

Accepting this dialog will show another dialog where we can define our block (Fig. 9).

Snap! Programming System, Fig. 8 Creating a new *cross* global command block under the *Pen* category

Snap! Programming System, Fig. 9 The *cross* block sets the pen down, moves the sprite in a cross pattern, and then sets the pen back up again

Blocks in Snap! can have parameters, which we can use to modify their behavior accordingly. We could, for instance, add a *length* argument to the *cross* block that defines how long the four

arms of the resulting cross drawing are. To do so, we need to edit the block by selecting *edit* from its contextual menu (right-click on the block for GNU/Linux or Windows users and command-click for MacOSX users) and then add the missing text and parameters by using the little plus-sign-shaped buttons on the block label (Fig. 10).

This new block can be now used as if it was any other block in the system and will be graphically and functionally indistinguishable from the native ones (Fig. 11).

Custom blocks being first class means that we can also use them to define other custom blocks or even to define themselves recursively. That allows us to build a new *fractal cross* block that makes use of itself to draw a fractal cross figure, where each arm ends in a cross half the size of the previous one and results in a square pattern (Fig. 12).

Snap! Programming System, Fig. 10 The new *cross* block definition, after having added a new *of length* text part and a *length* parameter to it. The pound symbol next to the parameter indicates that we are expecting it to be a number

Closures

Closures are programming constructs that allow us to deal with code as if it was data. *Full closures*

Snap! Programming System, Fig. 11 The *cross* block being used to draw crosses of random arm length

Snap! Programming System, Fig. 12 The new *fractal cross* block definition, plus an example of the drawing it generates when used with an arm length of 60

capture the context in which they are created, including the values of any variables in their scope. A full closure is, in a way, like taking a snapshot of a piece of code at a particular moment in time, so that invoking that closure later on will be like running it at the moment of its creation, including the state of the program at that past moment.

This lets us play with code in a substantially different way, even allowing us to define our own control structures. In fact, some computer languages – like Smalltalk – implement all of their control structures by means of closures, without the need of any primitive expressions or reserved keywords.

Snap! represents closures as *ring blocks*. A ring is a special graphical structure that encloses scripts and turns them into first-class data (Fig. 13).

A *ring* is, actually, a procedure without a name, and clicking on the right-pointing arrow on its

Snap! Programming System, Fig. 13 A *ringified* addition block

Snap! Programming System, Fig. 14 A *ringified* addition block with a parameter

right edge will let us add parameters to this procedure (Fig. 14).

But these procedures are special in that clicking on them will not result in them running. As explained before, these constructs convert code into data, so clicking on them will actually just return the data they hold (i.e., the closure

itself). In other words, if we understand procedures as verbs, then putting a ring around a verb is turning it into a noun.

To run these, we need to use one of the two special blocks Snap! provides, namely, *run* and *call*. The first one is meant to be used to execute a ring as if it was a command block, whereas the second one will execute it as if it was a reporter. That is, the second one – *call* – will expect the ring to return a value (Fig. 15).

We have just created an anonymous procedure that adds 1 to any number, but up to here it seems that rings only add complexity to something we could have very much easily achieved by just using the addition block by itself, so let us find an example that shows the value of closures a little bit better.

Rings turn any stack of blocks into a parametrizable function that can be treated as data and, as such, can be passed to another procedure as a parameter, in the same way that we can pass a number, a string, or a Boolean as a parameter. This allows us to, for instance, map the items of a list into a new list where each item has been applied a

function, without the need of using any iterators or indexes. From a mathematical point of view, this could be seen as the application of a function over a vector (Fig. 16).

As a little syntax sugar goodie, Snap! will automatically fill up any empty input inside the body of a ring, letting us rewrite the previous code in a shorter form with exactly the same functionality (Fig. 17).

This automatic parameter filling lets us easily map a list into another list where each item maps to its own double (Fig. 18).

As a matter of fact, the *map* block is actually implemented in Snap! itself, and, internally, it takes a function as a parameter and iterates over a list to apply that function to each of its items (Fig. 19).

As a curiosity, even the *for each* block used inside the *map* block has been implemented as a custom block that takes a function as a parameter and runs it for each item in a list (Fig. 20).

These functions that take other functions as parameters and apply them to every item on a list are called *higher-order functions*, and they

Snap! Programming System, Fig. 15 Calling the ringified addition block with one parameters and getting back the result the adding 1 to that parameter

Snap! Programming System, Fig. 16 Mapping the *add 1* anonymous procedure to a list and getting back a new list where each item has been incremented by 1

Snap! Programming System, Fig. 17 The same application of map over a list but this time with automatic parameter filling

Snap! Programming System, Fig. 18 Using the automatic parameter filling feature to double all numbers in a list

Snap! Programming System, Fig. 19 A simple, iterative implementation of the *map* block

Snap! Programming System, Fig. 20 A simple, iterative implementation of the *for each* block

represent one of the most useful applications of closures in computer science. Indexes and iterations are processes that are much closer to the way computers work than to the way humans think, which is why, in functional programming, *HOFs* are the natural way to transform lists and perform operations over their items.

Social Media and Networks as Digital Instruction and Learning Platforms

Yaacov J. Katz

 Ramat-Gan, Israel
 Michlalah – Jerusalem Academic College,
 Jerusalem, Israel

Introduction

Mobile learning is an evolving technology that utilizes the advancements in mobile computing to enhance education. In mobile learning portable devices such as laptops, tablets, iPads, and smartphones are used as platforms for presenting learning content using Internet-based databases.

The widespread popularity and availability of mobile devices have led to the development of mobile learning as a legitimate delivery platform in the educational process, and mobile learning provides a range of platforms and opportunities for teachers and students in interactive learning environments. Knowledge is no longer confined to classrooms, and it is now possible, feasible, and sensible to provide learners with access to knowledge via mobile learning without the constraints of time and location (following Neumann 2015).

Smartphones are now universally accessible and have become an integral part of daily life. In a recent report published by the Group Special Mobile Association (GSMA) in 2017, there will be an additional one billion subscribers by 2020. This trend is not only evident in the developed world but is characterizing the developing nations as well. In Asia, the Middle East, and North Africa, mobile penetration reached 50.2% in 2014 and expected to rise to 54.3% by end of 2020. In education smartphones are becoming increasingly popular among students (Domingo and Gargante 2016) and have proven to be successful in classroom utilization. Adolescent and young adult students increasingly view traditional learning platforms as somewhat boring and uninteresting; thus smartphones increasingly serve as valid alternative digital instructional educational platforms. In fact, the younger generations of students are more open and keen to embrace smartphones in the learning process (following Katz 2018).

Social Networks and Learning

Most students today are part of the Net Generation, sometimes called the Millennial Generation. This group of students has grown up with information technology all around them and is adept at social networking. They learn and communicate using technology, and as such, they expect their teachers to integrate technology into the classroom learning process. Mobile learning via smartphones is the popular and preferred technological platform for utilization of social

networks although laptops, tablets, and iPads can also be effectively used for mobile learning. Social networks may be defined as applications that enable users to communicate with each other by posting information, comments, messages, images, etc. Education and learning are perceived to be specific domains that can greatly benefit from social networks, and recent studies have indicated the increasing effectiveness of the contribution of social networks to the learning process. Social networks can support learning in general and, more particularly, problem-solving, communication, and collaboration with teachers and peers. Social networks represent a common space where friends can share information that can be viewed by others. Studies have shown that students spend a significant amount of time on social networks, checking and engaging in a variety of activities. Thus, social networks, coupled with appropriate pedagogical methods, have the potential to promote learning in educational frameworks and settings. Research results have intimated that social networks as educational tools in the academic landscape are catching on fast as colleges recognize the potential to use the networks for learning and learning via social networking is positively received by university students and contributes to the enhancement of student performance in the learning process. Social networks afford ample and potentially effective opportunities to improve student learning at elementary and secondary schools as well as university levels (following Katz 2014; Raspopovic et al. 2017).

In sum it may be said that research literature offers increasingly widespread evidence that supports the notion that social networks contribute to the fostering of student learning at all educational levels. In the following paragraphs, the different social networks commonly utilized in the learning process will be presented.

Social Networks as Learning Delivery Platforms

Social networks may be defined as technology-based applications that utilize mobile learning

technology to enable users to communicate on any number of topics. Recent studies have indicated that the field of education is a specific domain that can greatly benefit from the utilization of social networks in as well as out of the classroom. Learning is a social process of acquiring knowledge developed by individuals. The interaction between learners has been shown to enhance students' learning capacities. Thus, social networks within which people communicate and interact can contribute to the learning process by expanding the possibilities of learners to interact with their teachers as well as with their peers, thereby reaching new sources of information. Social networks as educational tools are catching on fast as universities, colleges, and schools recognize the potential that they have for the learning process. Research results have indicated that learning via social networking is positively received by students and contributes to an enhancement of student performance in the learning process and positively stimulates learning activities (following Katz 2014; Alkhathlan and Al-Daraiseh 2017).

In summary it may be said that research literature offers increasing evidence that supports the notion that social networks contribute to the fostering of student learning at the university, college, and high school levels.

SMS as a Learning Delivery Platform

As mobile technologies have developed, smartphones are increasingly being used as a learning platform. SMS messaging is used pervasively among students who are increasingly willing to use text messaging for educational purposes. This willingness to adopt text messaging for educational purposes involves a shift in perception on the part of most students who use these platforms primarily for social purposes. Thus, text messaging, together with students' willingness to use such technologies for academic purposes, has motivated authorities in universities and schools to implement SMS messaging to students' smartphones as a legitimate learning delivery strategy. Research results have indicated that when students receive text messages from a teacher, they feel more connected and think

more positively about the teacher and classroom activities. In addition, the use of SMS text messaging facilitates a more intimate student-teacher relationship, and text messaging strengthens social ties between groups of students for academic purposes (following Katz 2014).

Mobile-assisted language learning (MALL) via smartphone-based SMS delivery is rapidly becoming a legitimate and effective platform for vocabulary learning, and results of research studies have indicated that SMS delivery of vocabulary has a more significant effect on students' vocabulary retention than traditional instruction based on the use of dictionaries. In addition empirical results confirm that students who study language via SMS delivery are more enthusiastic about their learning of language idioms and attained higher scores on an achievement test than their counterparts who studied idioms by traditional teaching methods. Also, students who received English vocabulary lessons through the medium of SMS delivery performed significantly better on a vocabulary achievement test than students who received their vocabulary lessons by way of traditional face-to-face instruction. It has been suggested that the extra exposure to language and the reliance on phonological awareness and retrieval to compose and read text messages may explain positive, reciprocal relations between SMS text messaging and developing literacy (following Katz 2014; Ouellette and Michaud 2016).

In sum it is becoming increasingly clear that smartphone-based SMS messaging is rapidly infiltrating the educational process in universities and schools and is becoming commonly legitimized as an effective delivery platform for learning in general and for language learning in particular.

WhatsApp as a Learning Delivery Platform

Another social network application associated with mobile technology is WhatsApp instant messaging. Results of research studies have indicated that the WhatsApp application has a positive impact on learning success and its use is substantially welcomed by students in universities and schools. Students favor the use of smartphone-

based WhatsApp learning delivery in comparison to other types of social networking applications that serve as learning delivery and management platforms. WhatsApp delivery platform has the power to enhance students' learning and is a user-friendly mobile application that contributes to the promotion of learning and student satisfaction with the learning process. Students who used WhatsApp as a smartphone-based learning delivery platform improved their reading and writing skills, and the use of WhatsApp as a learning tool increases student curiosity and motivation in the learning process. In addition, students who used WhatsApp in the learning process enhanced interaction with their peers, fostered rich dialogue in the learning situation, increased sharing of knowledge among learners, and created an enjoyable collaborative atmosphere with peers. Research results have confirmed that different social network tools, but most especially WhatsApp, are advantageous in the learning process because of the integration of learning as well as social interaction in the classroom.

Results of recent empirical studies have indicated that WhatsApp provides students with an opportunity to express themselves freely in a non-limited environment thus eliminating the relatively low active involvement of students characterizing classroom lectures. WhatsApp technology also improves learners' active classroom involvement in learning. In addition, WhatsApp facilitates the creation of a positive social environment, develops a sense of belonging and community among students, and enhances dialogue between the students and teachers as well as between students and their peers to enable them to share information and operate as a team. Students are able to support each other by answering each other's questions and sharing their findings. Moreover, the utilization of WhatsApp has been shown to increase the accessibility of learning materials that enrich learning activities (following Katz 2014; Awada 2016).

From the above evidence, we may conclude that WhatsApp use as a learning delivery platform can effectively enhance learning as well as

collaboration and cooperation in the university or school classroom.

Facebook as a Learning Delivery Platform

Facebook, in addition to being the most popular social network for social groups, has also become a mobile learning-based learning resource well-suited to use with smartphones. From the results of numerous research studies, it is apparent that students value Facebook for providing an informal and motivating learning environment and that learning via Facebook delivery enhances learning performance of students. In addition, there is a clear indication about the positive potential of Facebook as a learning delivery platform at the school and university levels. When used as a learning delivery platform, Facebook enhances critical collaborative thinking, analytical thinking, and learning motivation as well as student-centered and social learning. There are empirical research indications that Facebook-based learning facilitates language learning as well as the learning of historical and cultural concepts. From the social point of view, there are indications that Facebook learning delivery leads to the narrowing of social gaps between students studying in more elite and less elite schools (following Katz 2018).

Results of recent research studies have also confirmed that the use of Facebook as a learning delivery platform leads to a higher level of student engagement with emphasis on increased student interaction with teachers as well as with peers. In addition, Facebook provides students with a way of maintaining and strengthening social ties, which are beneficial in academic settings. Similarly, the inclusion of Facebook in educational settings at one and the same time (a) enhances personally significant approaches to learning and self-expression in learning and (b) encourages students to build social connections that facilitate collaborative and peer learning. Facebook-based learning delivery also enhances student motivation and satisfaction with the learning process (following Carmichael and MacEachen 2017).

Thus, it appears that Facebook can serve as a reliable mainstream learning delivery platform

that positively contributes to students' academic attainments and at the same time uses social interactions between students and their peers as well as between students and their teachers to enhance their all-round performance.

Twitter as a Learning Delivery Platform

Twitter is another mobile-based technological application that may be defined as an online social networking service on which users post and interact with messages known as tweets. Tweets were originally restricted to 140 characters which limited its viability as a learning delivery platform, but in November 2017, this limit was doubled for most languages, thereby increasing the suitability of Twitter as a learning delivery platform. Users access Twitter through its website interface and use their mobile smartphones as receivers of the Twitter tweets. Twitter has increasingly become a mobile technology introduced into education as a learning delivery platform. Recent research suggests that within an academic environment, the use of Twitter adds to educational community building by offering students and teachers the ability to continually inform each other about what they are learning, discovering, or experiencing. Numerous studies have examined the utilization of Twitter in academic environments. Research results have indicated that the use of Twitter as a learning delivery platform can be responsive to student's learning needs. Specifically, Twitter can change classroom dynamics and significantly enhance the sharing of information. In addition, the use of Twitter can support learning beyond the traditional classroom through a constant flow of information between students and between students and teachers without limitation of time or location. Empirical research findings have confirmed that Twitter can serve as a powerful tool for enhancing social presence in addition to establishing informal, free-flowing communication between and among students and teachers. Furthermore, Twitter can help increase understanding of course materials as supported by the interactive environment and affiliated rapid feedback (following Thoms and Eryilmaz 2015).

There is increasing evidence that the use of Twitter in university courses as well as in the school classroom enhances students' learning capacity and potential. Research results have indicated that the use of Twitter at the university and high school levels enhances learning collaboration among students, increases learning curiosity and motivation, encourages students feel that learning could be trendy and fun, and focuses the attention of students on the topic under study. Additionally, empirical research results have confirmed that the use of Twitter for learning delivery leads to a positive effect on students' achievement as well as enhances students' willingness and desire to engage in learning tasks (following Katz 2018).

Thus, it appears that Twitter is an efficient mobile social network application that can positively promote student learning, student achievement, student curiosity and motivation, and student social interactions.

Affective Attitudinal Variables and Social Network Learning

Affective attitudinal variables, such as perceptions of user-friendliness, learner curiosity, learner motivation, and learner satisfaction, are some of those empirically known to be positively related to enhanced learning delivered via social network-based delivery platforms. Numerous research studies have indicated that the SMS-based, WhatsApp-based, Facebook-based, and Twitter-based learning delivery platforms are perceived by students to be more user-friendly than are more traditional learning delivery strategies. Recent research results have also testified to the positive significant relationship between learning achievement attained by students who utilized SMS, WhatsApp, Facebook, and Twitter delivery of learning and positive feelings of learner curiosity, learner motivation, and learner satisfaction with the learning process as perceived by these students (following Katz 2014, 2018).

Thus, it appears that when used in the educational process, the abovementioned social

networks indeed contribute to students' all-round performance which includes enhanced learning achievement as well the promotion of positive affective perceptions associated with their learning.

Conclusion

The empirical research results presented above indicate the potential of social networks as legitimate mobile learning delivery platforms. The four different social networks addressed (SMS, WhatsApp, Facebook, and Twitter) have been shown to yield a similar (but not identical) positive contribution to enhanced academic and scholastic achievement in universities and schools. In addition, the four social networks have also been shown to enhance students' perceptions of the user-friendliness of the learning delivery platforms as well as to encourage learner curiosity, learner motivation, and learner satisfaction with the learning process when compared to more traditional classroom-based learning delivery platforms. The present study indicates the potential of social networks as learning delivery platforms at the university level, and university policy-makers are urged to take note of this significant technological development.

The empirical results that indicate that social networks such as SMS, WhatsApp, Facebook, and Twitter learning delivery platforms contribute to positive learning and to positive affective feelings have led to the increasing introduction of these mobile-based applications into the repertoire of learning delivery platforms available for students in universities and schools. One may conclude that social networks have the proven potential to be utilized as legitimate learning delivery platforms that are competently able to enhance both cognitive and affective correlates of all-round student performance. Thus, the time is ripe for educational authorities to acknowledge the viability of social network applications such as SMS, WhatsApp, Facebook, and Twitter as acceptable learning delivery platforms at the university and school levels and seriously

consider the mass introduction of these mobile learning applications into the mainstream educational process.

Introduction

Technology has facilitated the rediscovery of traditional teaching methods by incorporating pedagogically useful features in a multidimensional environment. A by-product of the advancement in technology is social media – a dominant social interaction technology that has a plethora of uses. Social media can take different forms encompassing blogs, discussion forums, wikis, video-sharing sites, photo-sharing sites, social bookmarking, and social networking sites. Social media can be defined as a web-based technological platform for online communication that enables users to connect and interact, share ideas and information, build and engage social networks, and develop online communities. To maintain consistency, the term social media in this entry relates to all its different forms, unless explicit platform names have been used.

Social media has reshaped the way people communicate and interact, and its influence has not escaped the tertiary education sector. With smartphones and other mobile computing devices in easy access, the ubiquity of social media has increased. Social media platforms such as Facebook, Twitter, Google+, YouTube, Instagram, and LinkedIn are increasingly used to connect the community of learners and teachers. It

can be argued that people live on social media as teens and young adults worldwide spend an average of 188 minutes daily on social media (Statista 2017). If students are spending 3 hours a day on social media, then educators should consider reshaping their pedagogical practices and approaches to reach out to them via social media. Due to the significance of tertiary education or higher education in societies globally, and the amount of time students spend on social media, this nexus deserves attention, particularly with a view to seeing how social media can be used in tertiary education. Social media provides pedagogical, social, and technological benefits and has the potential to be widely utilized in higher education (Chugh and Ruhi 2018).

In order to harness the power of social media, it is crucial that educators understand its lacunae and forte. A one-size-fits-all solution may not be possible or advisable, especially when educational outcomes need to focus on curriculum, content, and collaboration. From an educational context, social media can undoubtedly prove to be a trusted platform for information dissemination, sharing and interaction, and easy accessibility to educational content. The role of social media in the education sector is not just limited to an educational context (teaching and learning), but it also plays a vital role in marketing, promotion, and generally reaching out to students via updates and announcements. However, the main focus of this entry revolves around the role of social media as a tool for teaching and learning activities.

In the pursuit to address this main focus, this entry first considers the benefits of social media for tertiary education. It then outlines some uses of social media for tertiary education. This is followed by the challenges of social media for tertiary education. Guidelines for social media usage in tertiary education are then outlined. Finally, the key premises of the entry are summarized.

Benefits of Social Media for Tertiary Education

For students, social media is an exciting and captivating tool that has opened doors to a wealth of

information, including huge networking opportunities and, above all, convenient access. Students appear to spend a lot of their time on social media. Thus, incorporating social media into teaching and learning practice and diverting the attention from casual socializing and gaming to social learning could prove to be valuable. Through a review of the literature, Tess (2013) highlighted that the majority of studies on social media usage in higher education classes had reported more positive than negative consequences for students. Students have a positive perception of using social media to enhance teaching and learning activities (Balakrishnan et al. 2017), and the use of social media technologies has also shown to increase academic performance of distance education students (Arif and Kanwal 2016). Social media use, as well as teachers messaging students, improved relationships and connections between students and staff, leading to improved class attendance and higher rates of completion (Callan and Johnston 2017). Social media can also facilitate distance learning by providing easier access to subject content in a variety of formats. As students are expected to conduct some form of research during their studies, social media gives them access to a wide range of information, often in a quicker way than traditional research methods. Social media platforms also enable students to consult others who have done similar projects or interact with experts across the world.

Essentially, education is a social process, and social media enables the process further by allowing students and teachers to interact, engage, and learn without worrying about geographic distance. Social media is also about staying connected. Having continuous access to online classes and staying connected to lecturers, tutors, and peers facilitates access to information when needed even when the students are away from traditional classrooms. Teachers use social media platforms with the aim of facilitating the learning process. Social media increases student collaboration and interactivity and enhances interaction between students and teachers (Sugimoto et al. 2015). Usage of social media for teaching and learning activities has also shown to increase trust between students and teaching staff (Ossiansson 2010). Social media allows students to

voice their opinion freely. This works in favor of students who are shy and often not confident in expressing their opinion in person. This also implies that introverted students are not disadvantaged.

Social media is also a valuable marketing recruitment tool that aids students in the educational decision-making process (Galan et al. 2015). Social media enables tertiary educational organizations to provide easy access to a variety of information about student life, university events, unit and program offerings, job opportunities, and so forth. All this information is used by students when they are evaluating study alternatives. The benefits realized through the use of social media in the facilitation of the recruitment process equally apply both to students and staff, as staff may be searching for similar information when applying for jobs. Social media is also used to enhance the interactions of alumni with their host institution. The interaction process is helpful not only in keeping alumni connected but also for fundraising and mentorship opportunities.

Uses of Social Media for Tertiary Education

In the context of teaching and learning, previous studies have outlined that social media has many uses, which includes, but are not limited to, engagement and reflective learning (Joshi and Chugh 2009); developing new literacy practices through text-making (Davies 2012); building social connections (Galan et al. 2015); delivering prior reading material for online interaction and in preparation for in-class discussion (Dyson et al. 2015) and academic-related activities (Khan et al. 2016); informing students about subjects, schedule changes, and resource requirements (Callan and Johnston 2017); and communicating with teachers and peers (Evans 2014). This demonstrates that social media provides numerous possibilities for educators to consider in their learning and teaching endeavors.

Social media can be used to organize class projects, provide supplemental help, generate online discussion, administer subject-related content, post notices and reminders, and generally enhance student interaction (Gettman and Cortijo

2015). Specifically, YouTube can be used by teachers to upload videos of assessment activities, sharing educational content and how-to explainers. This will also lead to self-paced online learning. Students can be required to record their assessments, such as presentations and role play, and upload them to YouTube. Lectures can be delivered live via Facebook, and the subsequent discussion can take place right under the video via comments. This essentially creates a discussion-like online space that allows students to ask and answer questions from each other and from teachers too. Social media can also be used as a tool to monitor posts that indicate conflict or threats. Often, students complain about resources or infrastructure on the institutional social media pages or groups. If correctly monitored, the problems can be addressed in a timely manner.

Social media usage is also exponential in the tertiary education marketing domain, where institutions are using it to canvas their course offerings, attract students, and then continue interacting with them on various social media platforms. Sharing information about campus events, as well as sharing and tagging of photos, creates an informal social network that enables students to further engage in the promotional process. Prospective students use social media channels to find out about universities. The International Student Survey by Hobsons (2017) showed that 82% of international students used social media to research universities even before making an enquiry. The study also found a positive correlation between the popularity of a university's social media platforms and international student recruitment numbers.

Challenges of Social Media for Tertiary Education

A study by Moran et al. (2011) highlighted key barriers to social media usage by higher education faculty. These were lack of integrity of online submissions, privacy concerns, lack of integration with existing learning management system, steep learning curve, and lack of institutional support. Students are concerned that their personal information could be seen by their teachers (Akçayir

2017). The concerns of privacy invasion on social media, especially when teachers and students are able to see each other's profiles and access personal information, are a major challenge. Another negative effect of social media is that some students might unknowingly publish content that might harm their reputation, which might have an effect on their study too. Students who freely participate in online debates and express opinion only on social media miss out on developing public relations skills. This might have a debilitating effect on their confidence in public speaking and lead to social interaction problems.

The use of social media for learning and teaching activities often implies that academics have to deal with an assortment of complex university policies and procedures and this can often lead to confusion (Willems et al. 2016). This frequently creates tension, as academics struggle in the debate of whether to use social media for their teaching and learning activities or not. On the other hand, some teachers' conservative attitudes about the utilization and experimentation with technological innovations also contribute to the lack of social media usage (Callan and Johnston 2017). Another challenge is that some academics may not be familiar with social media and how best to use it to improve pedagogical practices. The problem only exacerbates with so many different social media platforms in existence, each with its own bells and whistles.

Social media is also seen as a distraction from learning and teaching activities, primarily because it is mostly used for entertainment-based activities. Students see social media as a social networking tool rather than as a formal teaching tool. Hence, they are reluctant to use it for formal educational activities (Gettman and Cortijo 2015). Previous research has indicated that if social media usage in academia does not contribute to academic activities, its use is associated with negative academic performance among students (Junco 2012; Stollak et al. 2011). Having continuous access to social media is also distracting. It makes students less productive, and the temptation to check their social network sites for updates might take precedence over study. The relevance of information on social media is very important. Students could spend many hours browsing social media but not practically gaining

anything, except for the loss of valuable time. It can also be argued that in many social media groups created by tertiary education institutions, the students like to stay "in touch," especially when they are studying, but the "touch" and online social connection lose context once students have graduated.

Guidelines for Social Media Usage in Tertiary Education

There are an overwhelming number of social media platforms in cyberspace, some that are for general use and some that specifically cater to the education sector. Teachers need to decide what works best for their student cohort and for themselves too. One of the key factors that influence the choice of platform is the number of people using it. Facebook tips the scales in favor of all other social media platforms, primarily because of its more than 2 billion user base. Then, there is the need to consider the type of content that needs to be shared. If there is visually compelling content, then Instagram might be useful; but apart from photo sharing, Instagram has no apparent use for content sharing and educational interaction. YouTube can be a compelling platform to share videos to a large audience who are not necessarily part of an institution's social network. Facebook can be used to share videos and class notes and encourage interaction.

Some educational institutions use dedicated social media platforms such as Ucuroo, which limits any outsider access and provides more privacy. It is also linked to institutional accounts, negating the need for creating any further accounts. However, power lies in numbers, and if more people are using Facebook, then it is a clear winner. Hence, tertiary education institutions need to find ways of incorporating it for various uses, be it advertising, marketing, promotion, or importantly for learning and teaching activities. To alleviate privacy concerns, academics can create Facebook private groups for their classes, so the groups are not visible to anyone outside the private class group, although this does create a resourcing and monitoring issue. Facebook groups can be seen as a learning management system that allows easy dissemination of educational content and interaction between its members,

and academics can be made responsible for monitoring their groups. It is necessary for teachers to guide students about the privacy settings offered by social media tools such as Facebook and YouTube. To reduce the distraction of students, social media usage in academia should focus on the dissemination of relevant information, particularly so that it aids in meeting learning outcomes and scaffolding assessments. To keep alumni involved with their alma mater, meaningful social media posts should be created to keep them engaged.

Tertiary education institutions should not assume that academic staff are necessarily comfortable with the use of social media to enhance their teaching and learning practices. Ongoing professional development of staff should be provided along with examples and case studies of instances where social media usage has proved to be a success. Social media is constantly evolving, and students and teachers alike have to keep themselves abreast with trending technologies.

For effective use of social networking sites, documented guidelines can provide clarity and practical advice to positively channel online discourse (Chugh 2012). Dedicated social media policies around learning and teaching activities should be developed as generic social media usage policies are not sufficient to deal with the intricacies of the evolving and multifaceted nature of social media. Staff's usage of social media will be better guided by detailed policies that provide advice on confidentiality and codes of conduct. A code of conduct that outlines expectations of staff when using social media platforms is a necessity, especially because staff will be conducting official work on social media. It is also recommended that staff create a separate account using their institutional email for all learning and teaching-related social media interaction. This will also enable some privacy to be maintained as students will not be able to access personal information.

Conclusion

In every tertiary educational institution, critics and advocates will continue to debate the role of social media. Nevertheless, the widespread adoption and

use of social media has the capacity to change and revolutionize education. It has the underpinnings of becoming the classroom of the future. Leveraging social media to improve the educational process is imperative. Tertiary education institutions should not lag behind and must progressively consider incorporating social media into teaching and learning activities.

The value of social media usage in tertiary education not only lies in making announcements, marketing, and advertising but also for learning and teaching purposes. Social media can be implemented for pedagogical activities. It has the potential to improve academic performance, enhance interaction and collaboration, increase communication between teachers and peers, provide convenient access to teaching and learning content, and build relationships. However, social media may not necessarily work well for all teaching and learning scenarios, as a diverse range of pedagogical dynamics need to be considered. Hence, it should currently only be used to complement traditional practices over total replacement.

In implementing social media in tertiary education, if a bottom-up approach is not adopted by teachers, then a top-down approach may work, especially because the dominance of social media cannot be ignored. In doing so, the importance of institutional support to make social media implementation smoother should not be overlooked. Specialist teaching and learning social media champions should be identified. These people can play a pivotal role in promoting best practices while advocating and guiding other academic staff on incorporating social media in their subjects.

Just because social media is abuzz everywhere does not necessarily imply that it will work for tertiary education in the same way that it works in other domains. Staff need to be aware of the benefits, the challenges, and the opportunities that social media can bestow upon tertiary education institutions. This entry briefly outlined some of the key issues around social media usage in tertiary education institutions, in particular by highlighting some guidelines that could help in the adoption and adaptation of social media. The major contribution of this entry is to provide a tertiary information source for academics, administrators, and managers to enable them to conclusively understand some of

the main considerations that will influence the adoption and use of social media in tertiary education.

The blurred boundary between the formal and informal use of social media will always remain an issue of consideration, not just in academia but in varied other settings too. In spite of the drawbacks and challenges, social media will continue to evolve, becoming better integrated with learning management systems and changing the educational landscape.

Introduction

Over the course of almost 40 years, distance learning has transitioned from the periphery into mainstream education (Zawacki-Richter and Naidu 2016). As a branch of distance learning, social media has recently begun to attract considerable scholarly attention. Social media, also known as Web 2.0, is an umbrella term used to refer to Internet platforms, tools, or apps that support netizens to communicate and collaborate on mobile devices. Examples of social media include Facebook, YouTube, Youku, Twitter, Weibo, WeChat, and even different massive open online course (MOOC) platforms.

Social Media in Education

At the practical level, social media in education has been found to be useful as a method of teaching and learning. Due to its connection with the ubiquitous Internet, social media has the ability to connect teachers and students both inside and outside of classrooms, increasing the opportunities for peer support and collaboration, and teacher–student communication (Ding and Stapleton 2015; Li 2016; Al-rahmi et al. 2014). Social media is also claimed to be efficacious in increasing students' access to knowledge

(Li 2016), creating personal learning environments (Dabbagh and Kitsantas 2012), and facilitating informal learning (Dede 2016).

From a more transformative perspective, social media is also claimed to promote democracy and equity, as it exposes people to more educational resources at lower costs (Reshef 2016; Bramble and Lu 2016; Warschauer 2016). In China, the transformative properties of social media in the context of educating children from low-income families and school dropouts have been found to be particularly useful, as a mobile phone is a relatively cheap device for a low-income family enabling them to connect to the Internet (Wang 2016; Miller et al. 2016).

Social Media Surge in China

Social media is one of the most dynamic and innovative industries in China (Hu et al. 2017). Since the concept of MOOCs was imported to China in 2011, China has developed one of the largest MOOC user bases in the world, following the USA, Brazil, and India (Trehan et al. 2017), although only a few of the more prestigious universities are involved in developing MOOCs (Zhou 2016). The statistics of the population of MOOCs users were excluding users from other social media platforms.

According to a report on the Chinese education industry published by Deloitte in 2016, many traditional offline education schools have begun to offer online education (Deloitte 2016, May). An interesting phenomenon in China is that many non-education-related Internet companies have entered the commercial online education industry. Adkins (2015, March, p. 6) used an analogy to describe this situation: “imagine if Google, Google’s YouTube, Yahoo, eBay, Facebook, Microsoft, Microsoft’s Skype, Gameloft, Twitter, IBM, Amazon, and eHarmony all entered the commercial learning technology market at the same time.”

However, there has been little discussion in the literature concerning how social media has been integrated with shadow education in China. Shadow education is a key arena in

which Chinese parents compete for extra training for their children. Such competition centers upon China's National College Entrance Examination, the Gaokao, and the Senior High School Entrance Examination, the Zhongkao, where the stakes are high as students compete for admission to colleges and high schools. Also, the unequal distribution of educational resources across different regions and schools has further increased competition between parents and pushed them to use "shadow education" to maintain or gain competitive advantages in these important examinations (Yu and Ding 2011; Zhang 2011).

Shadow Education in China

Shadow education, which is also known as private supplementary tutoring, is fee-paid tuition outside of formal schooling hours (Zhang and Bray 2016). It "shadows" mainstream education offerings, mimicking the curriculum taught in schools. Bray (2009) has defined the common form of private supplementary tutoring as having three characteristics: privacy, supplementary, and academic. Privacy means that tutoring must be provided on a paying basis. Supplementary refers to the fact that tutoring is in similar subjects to those in formal schools, but delivered outside of school hours to supplement mainstream schooling. Finally, academic implies that tutees should be examined in regular schools. In the Chinese context, the definition is even broader. In a study by Liu and Bray (2017), academic and non-academic tutoring are included as examples of investment by families to improve students' performance in mainstream school examinations. A study by Wright et al. (2018) expands the definition even further, to include private tutoring for students at international schools in China offering the International Baccalaureate curriculum. However, the majority of research conducted in China focuses on shadow education as a parallel system to Chinese mainstream education at primary and secondary level (e.g., Kwok 2010; Zhang 2014; Zhang and Bray 2017).

With the increasing prosperity and competition within Chinese society in recent years,

shadow education in China has developed rapidly (Zhang and Bray 2015). However, this has also raised concerns regarding its negative impact on increasing social inequality (Zhang and Bray 2016), as parents who can afford supplementary education are those from more advantaged financial backgrounds and with more abundant educational resources. Previous studies indicate that in some schools over half of students receive private tutoring over and above school hours; this percentage increases to approximately three quarters in some urban areas (e.g., Zhang 2011; Zhang and Bray 2017). In China, the urban-rural division continues to be a cause of significant inequality in economic and education resources (Yang et al. 2014); it is hoped that the integration of social media will reduce this inequality.

Modes of Social Media Use in Shadow Education in China

Generally speaking, recorded video education, "1&M" (one teacher teaching many students), live education, "1&1" (one teacher teaching one student) live education, and homework helpers are the modes currently used in social media-integrated shadow education in China (China Industrial Information 2016). Recorded video education is the most traditional mode, and requires essential website functions for uploading, video viewing, and commenting. A large number of different schools, including the New Oriental School, accept this mode due to its low cost and "once-for-all" efficiency. Schools can record lessons and upload videos onto social media platforms, such as Youku, similar to YouTube, enabling students in different locations to watch online, at any time and from any place.

The 1&M mode is a livestream mode of teaching, where a teacher can simultaneously talk to multiple students in a chat room. Some large education corporations, such as Koolearn, Xueersi, and Global IELTS, have been early adopters of 1&M, building up online chat rooms and pitching lessons online. YY, a livestream

social media app, recently opened the floor for small business owners and self-employed teachers to deliver livestream classes. This increased the choices available to both students and teachers, breaking down barriers within and between cities, and even countries.

1&1 online education has also reached a prosperous stage, and since 2016, especially for English language learning, which in 2018 has become a favored area attracting investment from various financial organizations. Social media apps such as VIP KIDS and 51talk stand out as typical 1&1 mode applications, which invite native speaker teachers to teach Chinese students oral English via live chat. The 1&1 mode is beneficial for families who otherwise would not have access to native-speaker teachers for their children.

Recently, the theme of shadow education has been extended from personal teaching to homework assistance. Homework-helper social media platforms such as Zuoyebang and Little Ape are new brands exploring the concept of shadow education. These platforms also use livestream and live chat to connect teachers and students located thousands of miles away, to supervise and to give guidance to students who have difficulties completing homework. The user-friendly functionality attracts a certain group of clients, in particular those parents who are not able to provide academic help to their children.

Conclusion

The surge in social media usage in China has fueled its integration into shadow education, as businesses have begun to invent and adapt different apps and platforms to launch different modes of online classes, for example recorded video education, 1&M, 1&1 live education, and homework helpers. In this way, social media has increased the accessibility of shadow education resources for students, particularly those in rural areas with lower income and relatively fewer resources than their urban peers.

Introduction

Social networking (SN) has become one of the crucial technologies enabling several generations – baby boomers, X, Y, Z, and Alpha – to connect, communicate, and collaborate among their peers locally and globally. Several sectors, such as education, commercial business, entertainment, government, and others, are now using this technology to communicate and collaborate with their stakeholders, employees, and students. Education systems locally and globally have for many years been observing students' and businesses' needs in order to appraise and improve curricula so as to advance students' skills and meet business needs by using up-to-date technology in their teaching and learning practices. This technology can encourage and improve human endeavors to

acquire the students' academic skills required for study and the workforce. In the higher education sector, academics have begun to acknowledge and meet the needs of the new generations, Y and Z. These generations depend on the new technology in their everyday lives, especially for the purposes of study and work. Therefore, to encourage and motivate students, academics have begun to include some assessments and activities in their courses which involve the use of social networking tools such as Wikis, blogs, Facebook, and podcasts. This technology allows students to create and develop collaborative communication with other students and establish a niche community with similar interests and knowledge in the education domain as well as in business. As mentioned above, social networking has been adopted by the higher education sector as a means of improving the process of knowledge acquisition and ensuring social interaction among students and between students and lecturers.

Furthermore, this technology is not limited to the higher education sector, as both public and private sector organizations are now using it to contact and communicate with customers and to interact and collaborate with their stakeholders since the interface design has been developed with intellectual features to encourage user interaction. Moreover, SN tools have the advantage of being able to disseminate cutting-edge knowledge, foster collaboration, establish intercrossing relationships, improve communication skills, and facilitate the acquisition of new acquaintances. Moreover, it is an environmentally friendly mode of communication. However, SN can also pose several risks associated with cognitive, social, and physical development and security issues. Therefore, when institutions are planning to implement this technology in any field including the higher education sector, specific guidelines and models should be used to increase the advantages to students and stakeholders as a result of interaction, collaboration, communication, and connection; moreover, by following these guidelines and models, the risks, i.e., cognitive development, social development, physical development, and security, can be mitigated or even eliminated.

In this entry, the author will examine the meaning of social networking in general but will also examine its meaning in the context of higher education, discuss the social networking and education and social networking and education model (SNEM), and provide an example of social networking (i.e., Wiki). The entry also considers possible future research directions that can give further insights into social networking, especially in the higher education sector. This entry is organized as follows: introduction, social networking, social networking and education, social networking and personal and professional skills, social networking benefits and risks, social networking and education model (SNEM), implementing SNEM, and conclusion.

Social Networking

The use of technology in higher education is intended to improve collaboration, communication, cooperation, and connection among students and between students and lecturers. Currently, students in many higher education institutions are using various technologies such as Wikis, blogs, Twitter, Facebook, and Blackboard for tasks and assessments. World Wide Web (WWW) originated from the word web, and the web plays an important role in obtaining and disseminating information with the assistance of the technology. Social networking applications are based on variations of web technology, namely, Web 1.0, Web 2.0, Web 3.0, Web 4.0, and Web 5.0. Web technology began with read-only web and developed into read and write, semantic web, concurrent read and write web, and then tracking users' behaviors receptively (Benito-Osorio et al. 2013; Franklin and Van Harmelen 2007; O'Reilly 2007; Jiang 2014; Miranda et al. 2014; Powell et al. 2012; Spivack n.d.).

Several studies (Funk et al. 2013; Hazari and North 2009; Mahruf et al. 2012; Morgan 2009; Rao 2005) have confirmed that communication technologies, including the social networking platforms, play a major role in higher education in increasing participation and interaction among

students and between students and lecturers. It has been found that this type of communication has the potential to improve students' self-esteem and confidence, particularly through presentation and debate activities.

The web technologies serve as a platform for users and business to interact and communicate with other parties globally and locally. The Web 2.0 applications facilitate social interaction and access to information regardless of distance and time. The technology service is flexible, well-organized, actual, and user-friendly so as to meet users' and businesses' wishes and requirements. Figure 1 presents some of the social network applications, namely, Wikis, blogs, Mashups, Tags, and podcasts (Augar et al. 2004; Biasutti and El-Deghaidy 2012, 2015; Godwin-Jones 2003; Gokcearslan and Ozcan 2011; Heng and Marimuthu 2012; Zein 2014).

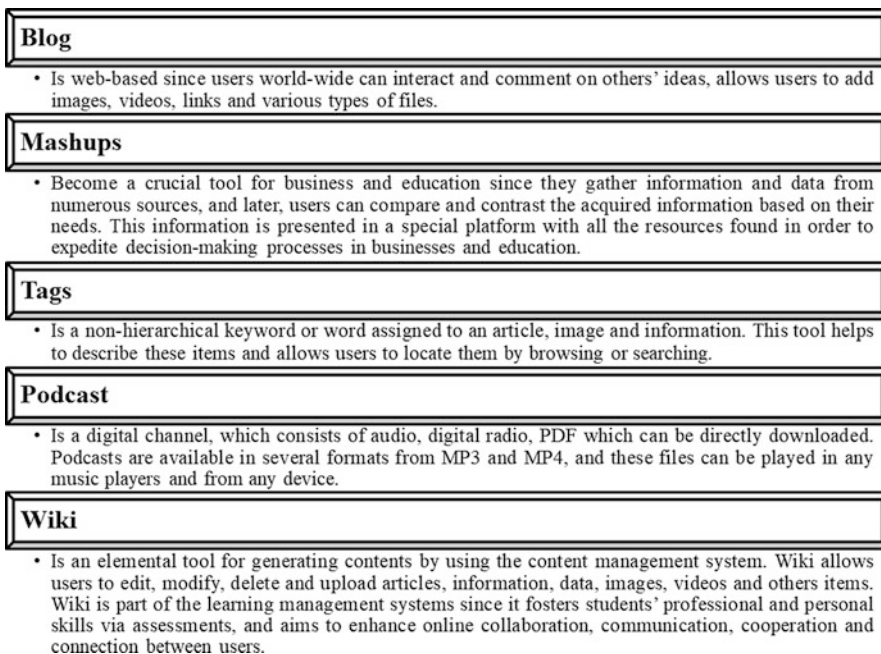

Social Networking and Education

Since last century, WWW has become the common information media utilized by

several generations to communicate, collaborate, connect, cooperate, and exchange information, knowledge, and data between students, organizations, and stakeholders locally and globally.

According to the Statista (2017) website, North America has the largest share of social networking usage in the world, followed by South America, East Asia, West Europe, Oceania, Central America, Southeast Asia, Eastern Europe, the Middle East, South Asia, Africa, and, finally, Central Asia. Figure 2 shows that this tool is used by more than three million users globally for sharing knowledge, data, and information in various sectors including the education sector. This development of social networking and the variety of user languages on the web has brought several advantages to both the business and education sectors. However, this tool also presents some risks to users.

Several studies (Cummings 2013; McCarroll and Curran 2013; Issa et al. 2014b; Özmen and Atıcı 2014; Duygu and Zahide 2015; Feinstein et al. 2015; Fox and Moreland 2015; Peldon and Issa 2015; Al-Oqily and Alkhatib 2016;

Social Networking in Higher Education, Fig. 1 Web 2.0 applications. (Prepared by Tomayess Issa)

Social Networking in Higher Education, Fig. 2 Global social network penetration rate by region as of January 2017. (Prepared by Tomayess Issa (Statista 2017))

Alqahtani 2016; Goktalay and Ozdilek 2016; Issa 2016; Turel and Bechara 2017; Vernon et al. 2017; Shi et al. 2018) indicate that SN is an online application that allows users to generate accounts for their profile and to add, edit, and delete their contacts and to meet and interact with real colleagues locally and globally. As mentioned previously, SN is intended to simplify the exchange and discussion of ideas and encourage collaborative communication and connection among users from various sectors including businesses and education. Social networking enables users to post, publish, and write articles or comments in sites such as Facebook and Google (Christoffersen et al. 2012). Currently, in the higher education sector, many academics integrate SN tools in their assessments and activities; these tools include Wikis, blogs, and discussion boards which are available in the LMS (learning management systems). The integration of these tools in the assessments and academic tasks will assist both students and lecturers to develop more interaction and communication, while students’ academic and students’ personal skills will improve as a result of undertaking tasks independently or in a team (Van Deursen et al. 2011; Bednarz 2014; Benson et al. 2014; Isaias and Issa 2014; Issa et al. 2014a; Tambe 2014; Chu et al. 2017; Novakovich et al. 2017; Ruge and McCormack 2017).

Social Networking and Personal and Professional Skills

The use of SN in higher education has transformed teaching and learning methods, since students become more independent learners by using various media such as Wiki, blog, and discussion board. These tools are user-friendly, and students can submit individual and team work to the lecturer for assessment based on rubric. These tools have been introduced in the higher education sector in order to improve both academic (reading and writing, research, information and technology, critical thinking, decisionmaking, digital oral presentation, and drawing (i.e., concept maps)) and students’ personal skills (i.e., motivation, leadership, negotiation, communication, problem-solving, time management, and reflection). These tools facilitate and encourage greater interaction, participation, debate, and discussion among students and lecturers when engaging in various assessment tasks and class activities (Issa 2014, p. 13). Moreover, several studies (British Medical Association 2004; Sancho-Thomas et al. 2009; Chu et al. 2017; Novakovich et al. 2017; Ruge and McCormack 2017; Taraghi et al. 2009) have confirmed that the use of technology (especially SN) will encourage students to become independent learners and will improve their academic and students’ personal skills, particularly since it enables them to regularly access their teachers’ feedback (see Figs. 3 and 4).

Fig. 4 Students' Professional Skills (PrK). (Prepared by Tomayess Issa)

Social Networking Benefits and Risks

On the other hand, to ensure a smooth transition from traditional teaching practices to e-learning teaching, lecturers will need to play a key role in the effective delivery of teaching, since the lecturer is a facilitator of teaching and learning, not the technology (Singh et al. 2005). Wilson (2001) suggests that three characteristics of the lecturer will control the degree of learning that occurs: attitude toward technology, teaching style, and the control of technology. On the other hand, the use of SN in the higher education assessments and activities will bring new benefits for students, namely, exposure to cutting-edge knowledge, the opportunity for collaboration and intercrossing relationships, enhanced communication skills, acquisition of new acquaintances, and an awareness of an environment-friendly means of communication. However, SN poses several risks associated with cognitive, social, and physical development and security (see Figs. 5 and 6).

Social Networking in Higher Education,
Fig. 5 Social networking opportunities in higher education. (Prepared by Tomayess Issa)

Social Networking and Education Model (SNEM)

Consequently, in order to implement SN efficiently, especially in higher education, the social networking and education model (SNEM) should be used (Issa et al. 2016). SNEM was developed and created based on an intensive study of 15 countries comprising both developed and developing countries. The study confirmed that using SN in higher education developed students’ academic skills, expanded their knowledge of local and global issues, and assisted students to study and work independently; moreover, the use of SN makes students more sustainable. However, SN can also cause anxiety, loss of interest in everyday activities, health concerns, and security fears. It may prevent students from undertaking their regular activities and, finally, may hinder the development of literacy and other fundamental skills. The SNEM contains the following elements: teaching methods, learning, technology design,

Social Networking in Higher Education,
Fig. 6 Social networking risks in higher education.
(Prepared by Tomayess Issa)

Social Networking in Higher Education,
Fig. 7 SNEM. (Prepared by Tomayess Issa)

and psychological aspects. Each of these contains several sub-elements to ensure the successful adoption of SN by the higher education sector.

Teaching methods consist of four elements: learning to learn, blended learning, pedagogy,

and curriculum (Murphy et al. 2004; Smith et al. 2009; Thrun 1996; Hughes-Wiener 1986; Oliver and Trigwell 2005; Driscoll 2002; Mockler and Groundwater-Smith 2015; Lalonde and Castro 2015). Figure 7 shows the sub-factors of each of

Social Networking in Higher Education, Fig. 8 Teaching methods. (Prepared by Tomayess Issa)

these. Learning to learn involves a set of principles and skills that will assist students to learn more effectively and so become learners for life. Blended learning combines face-to-face learning and online learning; these modes are essential in teaching and learning as a means of delivering the materials and information to students. Pedagogy and curriculum are related to teaching principles, professional practice, leading, guiding, and methods of teaching; on the other hand, curriculum relates to assessment tasks and activities which students are required to complete successfully in order to achieve specific educational outcomes.

The learning factor emerges from learning theories, in particular, learning styles and social learning. Learning theories are divided into two categories: connectivism and pragmatism (see Fig. 8). Connectivism is the theory for the digital age; it states simply that knowledge, data, and information are disseminated via a network of connections; therefore, the learning and teaching

process involves the construction and traversal of those networks, especially by using the latest technology (Siemens 2005; Duke et al. 2013). However, the pragmatism learning theory involves mainly hands-on problem-solving; teamwork, experimentation and projects, and subsequently the outcomes will be used for decisionmaking (Kivinen and Ristelä 2003; Wallace and Brooks 2015).

The learning style is based on Neil Fleming's VARK (1988) (Felder and Silverman 1988; Murphy et al. 2004; Fleming 1995): visual, auditory, read/write, and kinesthetic learning modes (see Fig. 9). Visual learners prefer to use concept maps, drawings, graphs, and flow charts instead of texts and audio material. This type of learner relies on visual cues and can better understand the information if it is presented graphically. These visual representations are tools that will help these learners to organize their ideas and understand the concepts being presented. Auditory learners prefer to listen and speak instead of taking notes from

Social Networking in Higher Education, Fig. 9 Learning. (Prepared by Tomayess Issa)

the lecturer. This group has the ability to discuss and debate with his/her classmates and lecturers as a means of understanding the concepts of the unit being studied. This group prefers to use the latest auditory technology such as MP3/MP4 audio which allows them to pause, forward, and rewind, especially those sections that they have difficulty understanding. The read/write learners prefer text, notes, and papers as a means of understanding concepts. These types of learners are able to interpret abstract perceptions and convey them through arguments and essays. Finally, kinesthetic learners prefer to learn through experience and practice; this means that they feel and live the experience in order to learn.

Social learning involves attention, retention, reproduction, and motivation (Bandura 1977; Cheung et al. 2015). Attention: learners need to pay attention in order to obtain the knowledge presented in the unit of study; any interruption or distraction will affect the learning process. Retention: this concept mainly concerns the process of remembering the information that the

student has obtained from notes, images, models, and other materials and resources. Reproduction: students are required to reproduce the information which they learned during the class, which in turn reflects their level of attention. This behavior will ensure that if students are receptive to information, their skills and observational learning will improve. Finally, students should have the motivation to repeat their performance at the same (hopefully high) standard and be aware that appropriate performance will be given positive recognition, and, conversely, substandard performance will have negative consequences.

The technology factor comprises three sub-factors, namely, system, social, and security (see Fig. 10). These sub-factors are essential for SNEM to ensure that social networking is effective and aligned with students' needs, especially in terms of the security of data storage and the user's private information. The system factor relates to the practical implementation of social networking in higher education; universities are required to provide hardware, software,

Social Networking in Higher Education,
Fig. 10 Technology.
(Prepared by Tomayess Issa)

Social Networking in Higher Education,
Fig. 11 Design. (Prepared by Tomayess Issa)

databases, Internet connectivity, and troubleshooting (support and help) for students and lecturers. The final sub-factor is social. For SN implementation to be successful, students need the latest applications and media such as Blackboard, Moodle, and other facilities.

In order to implement social networking without creating user frustration, design plays an essential role in this model, especially in terms of interface: usability, human-computer interaction (HCI), and navigation (see Fig. 11). Attention to these aspects of SN is vital since usability means that the interface is efficient, effective, safe, easy to learn, easy to remember, easy to use and to evaluate, practical, and visible and provides a satisfactory experience. The principles of HCI

are intended to ensure that the interface is practical and visually attractive in relation to text, style, fonts, layout, graphics, and color (Issa and Isaias 2014). The navigation sub-factor aims to establish communication between the interface and navigation in the hypermedia application (Issa 2008).

The final factor in SNEM is the psychological aspect (see Fig. 12); this factor will assist teachers to understand students' cognitive and behavioral attitudes toward the use of this technology in the learning and teaching process (Safuanov 2004; Lalonde and Castro 2015; Watson 1963; Monks and Kawwa 1971).

Furthermore, this factor will assist students to meet their study needs and requirements, since teachers using the technology play a major role

Social Networking in Higher Education,

Fig. 12 Psychological aspects. (Prepared Tomayess Issa)

especially in terms of activities and assessments. According to Issa et al. (2014c, p. 30), “The constructive feedback is intended to ascertain whether students are on the right track, and to allow students to learn from their mistakes and prevent future repetitions of the same errors. Furthermore, the adoption of this approach in postgraduate and undergraduate units will improve students’ confidence and motivate them to complete the assessment tasks on time, and most importantly, align with the unit objectives and aims.” The formative feedback is intended to raise students’ awareness and encourage, motivate, and inspire them during the learning process, fostering their independent learning and improving their students’ academic skills and students’ personal skills by using the technology and, in particular, accessing their teachers’ regular feedback. Furthermore, both formative and summative feedback will encourage students to engage with the unit and will provide an exciting, memorable, and motivating experience. Motivation is the factor that assists users to move toward a goal or aim, while the purpose of encouragement is to give courage, hope, and increased confidence to users to strive to achieve their aims. The idea of awareness is to have knowledge or judgment of something, while inspiration is a

process that takes place when a user sees or hears something that causes him/her to develop and generate new ideas (Business dictionary 2015; The Encouragement Foundation 2015; Psychology Dictionary 2015; What is How to Info 2015).

Implementing SNEM

The SNEM was implemented in one of the author’s postgraduate units by using the Wiki (WK) tool which is integrated in the Blackboard facility. The use of Wiki as a teaching tool improved the students’ communication skills (writing, interpersonal interaction, and presenting), as well as their critical and creative thinking (problem-solving and decisionmaking), and their technology and information literacy. Additionally, the incorporation of Wiki tool in teaching and learning practice, especially in the author’s teaching unit improved the quality of students’ work, their productivity, and self-confidence. Students added, modified, and deleted information and data by means of the Wiki tool, and this encouraged and developed their independent learning process during both individual and team activities.

Social Networking in Higher Education,

Fig. 13 Wiki rubric.
(Prepared by Tomayess Issa)

Students completed several challenging, practical exercises which required them to analyze and evaluate real case studies and to then upload the results to the Wiki to be evaluated by the lecturer and student peers. Subsequently, individuals or teams presented the results using PowerPoint slides or concept maps.

The Wiki submission was graded according to a pre-established rubric which contained the following assessment criteria (see Fig. 13): content (i.e., topic(s) is/are covered in detail with excellent examples; knowledge of subject matter is outstanding), organization (well-presented and organized, using headings or bulleted list to group related material), attractiveness/appeal (to enhance the Wiki presentation; student uses excellent choice of font, color, graphics, effects, etc.), contribution to group work and discussions (student contributes to and develops the class Wiki, by providing her/his opinion regarding her/his colleague's Wiki contribution), accuracy (student's observations and perspective were presented, explained, and demonstrated well), and structure and quality of writing (well structured (e.g., paragraphing; sentence structure; spacing;

spelling; proofreading; no HTML errors in Wiki, i.e., broken links and missing images; above-average standard of expression and presentation; excellent overall expression and presentation; accurate acknowledgment of sources)).

Students were very pleased with the use of the Wiki tool in the teaching and learning process, and their feedback was gratifying:

I was impressed by the way lecturer teaches the unit. It involves discussion as well as Wikis helps us to be self-involved as we come to know the current happenings around the globe (Student 1).

Adding content in a Wiki also has a more collaborative feel to it and feels less restrained so in my mind it allows for a more free flowing conversation to occur on the subject at hand (Student 2).

It motivates me to share my ideas using Wiki tool, let me access other updates, observe their writings and learn writing skills from them (Student 3).

I should say that all the skill developments method has been covered in this unite such as group assessments, group activities, investigation of journals, report writing, video presentations, strategy developments methods and the Wiki exercises. These skilled developments methods helped me to improve my professional and personal skills including the writing skills, thinking skills, speaking skills, reading skills and listening skills, time

management skills, flexibility skills and planning skills, determination, evaluation techniques and communication skills. Before starting this unit I must say that I am a little bit shy person, and fear to present my ideas and talk to others. Now I feel that I can talk with others without any hesitation and can present my ideas to others (Student 4).

By writing journals and WIKIs, I was able to improve my writing and research skills. Research took more time than expected but in the end, it was easy to filter the data and get the right information. It was sometimes challenging to present my ideas in writing but now I am comfortable and confident to write and explain to someone (Student 5).

With the individual Wiki exercises, I was able to improve expressing my ideas since most of the tasks required us to share our perspectives on different subject areas (Student 6).

Each lecture discussed a new problem and possible solution, the delivery method of these concepts including the videos, Wikis, slides, graphic contents were quite helpful in understanding the emerging problems of the new world and realizing the role that we –students and academics can play in addressing these issues (Student 7).

The Wiki exercises allow students to discuss and exchange views on new and interesting topics. This new form of teaching provides an open channel for students to communicate views and solutions to tackle the various cases posted (Student 8).

I have learnt how to use Wiki tool which is I think the best way to give our ideas and thoughts. In fact, I consider Wiki is one of the amazing things to share information with students and teacher as well (Student 9).

Group activities in the class have increased my communication skills as the students are from different communities and we have gained lots of knowledge from each other and a shared number of new ideas with each other regarding green IT and sustainability to do Wiki assessments. Also, we came to know up to what extent the different countries (developing and developed) are worried about this major issue and what they are doing at present to reduce and mitigate this big problem and save our mother earth for our future generation as there is no planet B to go after. Teamwork teaches us the corporation and sharing (Student 10).

Cutting edge knowledge

- New information and knowledge
- Up-to-date information
- Awareness
- Facts/aspects of the past

Collaboration

- Communicate with Peer
Frequently/different universities and communities
- Collaborate with Peer Frequently

Inter-crossing relationships

- Intercrossing relationship with my peers
- Study independently
- Overcome study stress
- Complete my study quickly
- Understand and solve study problem easily
- Scrutinize my research study easily

Communication skills

- Develop Personal and communication skills
- Develop professional attitude toward study and work
- Concentration

Be environment-friendly

- Sustainable person
- Reliable and scalable services
- Greener
- Reduce carbon footprint in my activities

Acquire new acquaintances

- Acquire new acquaintances (Work, Friendship, Romance)
- Do what I want, say whatever I want, and be whoever I want

Based on the above feedback, the Wiki tool has become an interesting and effective means for students to engage, collaborate, communicate, connect, and cooperate with their colleagues and lecturer to exchange information, knowledge, data, images, videos, and others. Furthermore, via this tool, students confirmed that their students’ personal skills and academic skills had improved. These included skills in communication, reading, writing, problem-solving, and decisionmaking, as the Wiki provides an open channel through which students can engage and exchange ideas and opinions regarding the Wiki activities. Students confirmed that the use of the Wiki tool in a postgraduate unit assisted them to understand the other students’ perspectives from a different point of view, as Wiki contributions are available to all students and lecturer, and students can view their colleagues work and learn from new information and knowledge regarding the same activities.

Furthermore, using Wiki in the activities will allow students to share information and interaction among students and lecturer and encourage the teamwork among students. By using Wiki for their tasks, students were able to better understand

the unit materials, as they were able to search and research information regarding the Wiki activities, most of which were related to the unit materials. This type of exercise will motivate students to engage in their teaching and learning activities with more enthusiasm. Lastly, learning through Wiki is different and unique as the student becomes more excited and motivated to complete the unit successfully.

Put concisely, social networking in higher education has become an essential and useful tool enabling students to obtain the necessary and cutting-edge knowledge offered by the unit via the activities. Moreover, it improves their academic and students’ personal skills and encourages greater collaboration between students and their teachers. The introduction of Wiki as a teaching tool in a postgraduate unit achieved various benefits in terms of cutting-edge knowledge, collaboration, intercrossing relationships, and communication skills (see Fig. 14).

On the other hand, using this tool in the correct way will minimize the SN risks associated with cognitive, social, and physical development and security (see Fig. 15). By completing the Wiki

Cognitive development	Prevents me from Concentrating on writing and reading skills
	Prevents me from the fundamental knowledge and skills
	Scatters my attention
	Decreased my grammar, proofreading, and deep thinking skills
	Distraction
Social development	Prevents me from participation in social activities
	Prevents me from completing my work/study on time
	Sick and unhealthy
	Bores, stress, depress, lonely, lazy, addict, gambler
	Insecure
Physical development	Receive an immoral image and information from unscrupulous people
	Prevents me from having face to face contact with family and friends
	No physical activities
	No shopping in stores
	No watching television
	No reading newspapers
Security	No talking on the phone/mobile
	Prevents me from completing my work and study on time
	Privacy; security and intellectual property concerns

Social Networking in Higher Education, Fig. 15 SN risks. (Prepared by Tomayess Issa)

activities (individual and teamwork) in the post-graduate unit, students reduced and diminished the cognitive and social development which is considered a good progress for both the students and the lecturers.

Conclusion

This entry introduced and discussed the meaning of SN in general and with specific reference to the higher education sector. SN tool is an essential and necessary tool for students as it assists them to acquire the skills necessary for their studies and for their future workplace. The SNEM was introduced in the entry to attract academic attention regarding the implementation of SN in assessments and activities and to reduce the risks and increase the benefits associated with SN in the education sector. Finally, this is a call for academics to use SN in assessments and activities, since this tool can offer outstanding benefits to students. However, SN can pose several risks. Therefore, when introducing any SN tool into the higher education sector, especially for assessments and activities, a model should be implemented to help ensure the success of SN in this context and to achieve the unit goals. Most importantly, this tool has the potential to assist, encourage, and motivate students to achieve their goals and acquire the skills necessary for their studies and in their future workplace. In the future further research will be carried out by the author to implement SNEM via diverse tools, i.e., blogs, Twitter, and other technologies, to compare and contrast the benefits and risks of these tools.

Social Networks in Higher Education Management

Lucía Melián-Alzola
Universidad de Las Palmas de Gran Canaria,
Las Palmas de Gran Canaria, Spain

Definition

A social network is a web-based application, a system of open relationships and exponential growth. On a social network, a user invites other users to establish an online connection via the platform. In turn, each user also creates their own group of contacts to create a network of connections (Assimakopoulos et al. 2017; Cheung et al. 2011). In the educational arena, a social network can also be a tool to support management decisions.

Introduction

In recent years, universities have faced various changes and circumstances that have affected the formulation of strategies and operational management. Among such changes – varying in nature and geographical scope – are, for example, economic changes, changes in the regulation of the education system, or the internationalization of education (i.e., Daniel 2015; Uslu 2018). In this context of change, the digital context generates new challenges and opportunities that influence different areas of the university's organization (academic level, provision of services, administrative management, relationships with stakeholders, agreements with other universities, etc.). Moreover, the technological revolution has influenced the way in which the current role of universities in society could be understood and how that role can be developed (Sadowski et al. 2017; Voss and Kumar 2013).

One of the digital options with an increasing presence in the world of higher education is the use of social networks (Peruta and Shields 2017; Voss and Kumar 2013). Social networks establish bidirectional relationships between users of the platform but also nodes that create a chain of relationship points and connections, creating communities. As a main purpose, social networks allow the creation, publication, and exchange of content. These contents can vary in nature (information, opinions, photos, videos, etc.) and purpose (educational, professional, social, cultural, economic, etc.). The interactivity and dialogue of this type of service, based on technology and functioning within a network, encourages users to produce content (producers), receive content (receivers), and discuss and share content (opinions, suggestions, links, etc.) (i.e., Boyd and Ellison 2007; Kane et al. 2012; Sobaih et al. 2016). Therefore, on social networks users expose themselves, accepting the rules of the game – give, receive, and contribute – and creating diverse and enriched digital scenarios. Thus, social networks allow the user to do the following, among others:

- Publish content of interest (news, articles, reports, etc.) in various formats (text, videos, photos, etc.)
- Create content from the content of other users, generating new knowledge.
- Collaborate with third parties, facilitating teamwork and sharing.
- Share content with other users of the social network, creating a sense of community.
- Relate to other individuals, responding to the needs of the individual as a social being.
- Learn from the content of other users.
- Strengthen personal self-esteem through publication, debate, and content defense.

There are a significant number of social networks, in terms of objectives, target audiences, and the platform's resources (Moreira et al. 2017). With general or horizontal social networks, users maintain contacts and converse on multiple topics (Facebook, Twitter, Google Plus, Instagram, etc.). As vertical social networks, there are specialized social networks that deal with specific topics, such as cinema (CinemaVip) and crafts (Ravelry), and professional networks are aimed at connections and professional contacts (Lindkedin, Viadeo, About.me, etc.).

Social Media Networks in Higher Education

The use of social networks has a growing presence in university life. Thus, it is common for universities to link the various social networks on which they have a presence on their websites. These networks include, for example, Facebook and Twitter. However, social networks must be considered as more than just technological resources but also as strategic allies. The university must be horizontal, integral, constructive, global, transparent, collaborative, international, and so on, and, in this sense, social networks contribute to this reality. After examining some examples of the application of social networks in university management, a model of the integration and development of social networks in higher

education institutions is proposed. This model aims to establish a frame of reference for the integration of social networks into the mission, vision, strategy, and action of universities.

Social Networks in Teaching: A New Teaching-Learning Model

In the last decade, the educational model for universities has focused more on the individual needs of the student. This new work scheme aims to promote, among other issues, the autonomy of students, collaborative work, continuous learning, critical thinking, social skills, and creativity. Brown (2012) and Arquero and Romero-Frías (2013), among others, recognize that new technologies represent these values. Thus, social networks have an important role in this new educational context because, among other reasons, twenty-first-century students are “digital natives.” Indeed, in general terms, university students use social networks in their daily lives and are receptive to any technological innovation. Among the most widely used social networks, both personal and academic, are Facebook and Twitter. The use of social networks in the teaching-learning process generates important advantages and possibilities (Sobaih et al. 2016; Arquero and Romero-Frías 2013; Demir 2018; Lambić 2016; Sharma et al. 2016). This paper emphasizes the following advantages:

- Access to academic material (lectures, exercises, etc.)
- Access to academic achievements (student's exam scores, evaluation of group activities, etc.)
- Share academic resources with one another.
- More personal and interactive communication with teachers and classmates.
- Work cooperatively by creating study groups.
- Continuous awareness of changes to timetables and the content of subjects.
- The expanding and enriching of content and ideas through debate and sharing.
- Continuous and dynamic relationships with teachers and classmates.
- More dynamism in the teaching-learning process.

- Receive support and academic advice in real time.
- Use and master technological tools and applications.
- Provide informal work environments in which to learn outside of the classroom.
- Nurture feelings of social belonging and community.
- Resolve doubts and clarify concepts as soon as the need arises.

Likewise, the use of social networks in the teaching-learning process influences academic results such as, for example, greater mastery and understanding of the subjects, more motivation and student satisfaction, a positive work climate, and better interpersonal relationships between students and teachers.

Social Networks in Research

Social networks play an important role in the field of scientific research. In this context, scientific publications, through their social networking platforms, have had an increasingly important impact on the academic field. Examples of social networks in research include Academia.edu, ResearchGate, Mendeley, or MyScienceWork. In addition, scientific networks are connected to other networks such as Facebook and Google Plus, which further increase the possibilities of visibility, connection, and interactivity. The advantages offered by this type of social network are numerous and relevant for the curricular development of the researcher within the academic world (Al-Aufi and Fulton 2014; Meishar-Tal and Pieterse 2017; Muscanell and Utz 2017; Roig-Vila et al. 2015). Among the possibilities that scientific social networks can offer are, among other things, the following:

- Upload and download of articles and abstracts.
- Share of research ideas and expertise.
- Academic visibility and greater scientific impact.
- Up-to-date information from publications in a scientific field.
- Belong to a related scientific community.

- Receive notifications of scientific events (conferences, lectures, etc.)
- Read recommendations to publish in scientific journals.
- Receive notifications of job opportunities in the academic field, such as posts at universities and research centers.
- Participation in scientific discussion groups.
- Get ideas and answers to research related questions.
- Follow other researchers (e.g., new publications).
- Know who and how many people have shown interest in your own publications.
- Access to specialized mailing lists.
- Create groups and workspaces at different levels (departmental, institutional, etc.)

As a result, researchers can raise their profile and professional prestige, consolidate their digital identity, and increase the possibilities of collaboration agreements or participation in projects or publications, among other benefits. Likewise, universities also obtain a greater presence and scientific prestige, improving their position in rankings, which also leads to an increase in student enrollment, agreements with other universities, university-business collaborations and agreements, and funding.

Social Networks in University Communication

Universities must be increasingly competitive, so they must enhance their brand image and international projection through an appropriate communication strategy. Information and communications technologies represent a communication channel that offers diverse resources and formats that enrich the message and reach many more recipients at a lower cost relative to traditional media. As an example, a digital option widely used by universities for communication purposes is corporate websites. Other options are social networks that contribute toward making communication more interactive and creating a sense of community, making the message participatory and collaborative (i.e., Alexa et al. 2012; Bélanger et al. 2014).

Regarding the use of social networks for university communication, universities have the possibility with social network sites to publish information using a wide range of multimedia resources (Galan et al. 2015; Peruta and Shields 2018; Le et al. 2019). Thus, universities can present their objectives and university policy (university mission, regulations, reports, minutes, financing, corporate social responsibility, etc.), academic information (subjects, teaching staff, teaching resources, curricular offer, etc.), management data (services, organization, schedules, results, etc.), extracurricular activities (special days, concerts, sporting events, conferences, exhibitions, job offers, etc.), and much more. The format of the content can be diverse, including text, videos, photos, links to other websites of interest, etc. On social networks, the content published by a university is enriched with messages, comments, links, videos, likes, and shares contributed by other users (students, companies, public bodies, etc.). Indeed, social networks are bidirectional, dynamic, and interactive. In this regard, their users expect to play an active role in the content and operation of the platforms. For this reason, universities must promote proactive and reciprocal communication and be open to suggestions and requests, inviting the contribution of content to the university community and always improving their own content and the format in which it is delivered.

In addition, communication on each social network is different and must be managed in different ways. Thus, for example, it is not the same to communicate on Twitter as on Facebook, since the number of characters influences the content of the message and each social network has different resources. Thus, the objective of communication on Twitter is to deliver brief and concentrated messages with quick responses. Facebook, on the other hand, is a more complex network with more digital resources (Al-Bahrani and Patel 2015; Tess 2013). For this same reason, social network users often use several platforms because they offer different services and resources and satisfy different objectives. As a consequence, universities must choose a combination of social networks according to the preferences of their

stakeholders, the resources and technological possibilities provided by each network, and the suitability of each platform for their communication strategy.

Social Networks in the Management of University Services

Universities are increasingly incorporating social networks into diverse services and operations. In this regard, the advantages of social networks in university life are numerous. The following are some examples of this reality.

Enrollment and guidance for the student. Universities design strategies to attract new students each academic year. Within the current range of options, universities publish information on their websites, create information brochures, organize open days, and visit centers of secondary education. One way to increase the number of students is to make use of different social networks. As indicated by Alexa et al. (Alexa et al. 2012), social networks could help prospective students to value the academic offer and evaluate the services and resources of the university, among other issues, so they can make more well-informed decisions. Therefore, it is important that students have guidance and support at all times (Sobaih et al. 2016; Koshkin et al. 2017). Moreover, the optimal management of the university's presence on social networking sites relies on its followers to positively identify with the university so that they will be more predisposed to enroll and make positive comments to other potential students. In this regard, while prospective students can find much of the information they require on university websites, social networks are interactive and collaborative environments. Consequently, social network users demand quick answers and close proximity, and, as Voss and Kumar (Voss and Kumar 2013) stated, universities should listen and answer promptly to their audience through social media. For this reason, universities must include interactive spaces on these platforms with academic and administrative staff ready to answer any questions, resolve any doubts, and meet the demands of potential students. On the other hand, universities must choose the appropriate message object for each type of social

network. Thus, to attract potential undergraduate students and young students, it could be appropriate to design messages for Facebook and Twitter. However, for postgraduate studies (masters, doctorate, specialized courses, etc.), the university promotion strategy could also focus on professional social networks such as LinkedIn.

International dimension. In recent years, the international dimension of universities has increased thanks, for example, to exchange programs, with social networks being an effective way to attract potential foreign students. To this end, universities should use social networks to provide these students with information that helps them make the right decision, offering different options (academic offerings, university residences, language schools, transportation, financial information, etc.) in different formats (text, videos, photos, etc.) (Le et al. 2019; Hamid et al. 2016; Vrontis et al. 2018). In the same way, universities must manage spaces of consultation on their social networks and respond as quickly as possible to all questions posed by students from abroad and in many different languages. The strategy for attracting foreign students and helping them in the process of registration would need to be coordinated with those responsible for exchange programs and international relations at each university. Finally, one way to attract students is to make it easier for social network users to tell of their experiences with the university.

Library services. University libraries have found on social networks an ideal digital medium for the development of their services. As example, Martin Marichal (Martín-Marichal 2013) shows that the use of different social networks (Facebook, Twitter, YouTube, Instagram, etc.) by Spanish university libraries is significant. This also contributes to the fact that a large volume of bibliographic material can be offered in digital format, such as e-books and online scientific articles, in a virtual environment. Regarding the type of content and resources available at academic libraries, there is a wide range of options, as recognized by Collins and Quan-Haase (Collins and Quan-Haase 2014) and Phillips (Phillips 2011), among others. Thus, on social networks,

libraries can transmit information about their services, provide access to catalogs, offer training courses, communicate schedule changes, and much more. In terms of multimedia, libraries can post photos and videos and links to other social networks and websites of interest. Information about academic, cultural, and/or social events happening at the university or elsewhere, such as conferences, shows, cinema showings, etc., can also be published. At the level of customer service, users can raise complaints and make suggestions, answer surveys, provide comments (hashtags), Participate in blogs, etc. In addition, libraries could create communities by inviting companies, public bodies, etc. to participate in their network, contribute value to the wider interests of the university community by publishing news of interest, and allow the users of the network to share experiences (literary, sports, gastronomic, etc.), among others. With all this, these platforms generate a continuous and dynamic interaction between the library and users of the social network, enhancing commitment to and identification with the university and making more effective use of university resources.

University Management Based on Social Networks

Based on the above, a social network management model is proposed at the university level, applicable to all spheres of action and to all interest groups (Fig. 1). First, the premises that must support the use of social networks, both at a strategic and operational level, are established. At a strategic level, the implications of the use of social networks are explained, not as a passive resource but as key factors in the new university management model. At the operational level, a series of recommended content and format features are described in the configuration and use of social networks.

Premises of Social Networks

The optimal use of social networks is characterized by a series of parameters or intrinsic qualities, as derived from Voss and Kumar (Voss and Kumar

Social Networks in Higher Education Management, Fig. 1 Social networks in higher education management

2013), Boyd and Ellison (Boyd and Ellison 2007), and Meishar-Tal and Pieterse (Meishar-Tal and Pieterse 2017), among others. This paper proposes a series of values that should serve as a frame of reference when higher education institutions use social networks in any field of their university activity.

- *Utility.* Social networks must offer useful content to users.
- *Creation.* Content contributed by a user generates new content by other users in the form of opinions, comments, links, uploaded documents, etc.
- *Altruism.* A priori, the economy of social networks is the “gift economy.” Put simply, users share content for free.
- *Cooperation.* Social networks are based on collaboration and user participation.
- *Community.* Social networks serve as a connection hub between users, creating communities.
- *Socialization.* People who participate in social networks seek to build relationships, that is, a connection with other people, whether academic, professional, scientific, or social.

- *Ethics.* Social networks are based on ethical principles of transparency, responsibility, and respect, among others.
- *Visibility.* Social networks represent an opportunity for projection and visibility, so the impact of behavior on the network is important.
- *Immediacy.* The response time in social networks has to be as short as possible. The user expects to receive an answer almost immediately.
- *Digitalization.* Users of social networks dominate, or are sensitive to, the development of new information technologies.

Strategic Agenda: Management Approach

The strategic agenda includes considerations regarding the management of social networks within the university environment, representing a frame of reference and antecedent for the implementation of the operational agenda. Authors such as Bélanger, Bali and Longden (Bélanger et al. 2014), Dumpit and Fernández (Dumpit and Fernandez 2017), and Sobaih et al. (Sobaih et al. 2016), among others, have contributed to the understanding of the management of social

networks from an integral perspective. In this model, the following is proposed:

- *Definition of the social identity of the university.* Universities must analyze, on the one hand, how new information technologies contribute toward developing their strategy and corporate image and, also, how they can improve them. In other words, these types of institutions must study how social networks allow their strategy to be implemented and, also, how they can influence their future plans. To do this, the current and potential use of social networks by different interest groups at the university must be known. Likewise, benchmarking exercises must be carried out, reviewing and monitoring current uses of social networks at other universities.
- *Integration between online and offline management.* Universities should integrate online management with offline management in order to maximize organizational efficiency and available resources. Thus, for example, social networks keep students informed of changes to class schedules, allow users to make complaints and suggestions about the operation of university services, and ensure that the educational offer has greater international projection. Universities must decide on the scope (objectives, activities, interest groups, etc.) of both online and offline management, that is, the synergies and differences between both scenarios.
- *Choice of social networks.* Universities should know the value or utility that each social network can bring to the university's objectives. Based on this, each institution must choose the optimal combination of social networks for their organizational identity. Moreover, the role of each social network and the interrelationships between them should be analyzed. For example, whether the same type of content will appear on different social networks. In addition, universities must identify which network or social networks are suitable for each interest group and according to which roles. Thus, educators can use Facebook in the teaching-learning process as teachers and ResearchGate as researchers.
- *Proactive management of social networks.* Universities should analyze the risks and opportunities that each social network provides in advance. From there, each institution can plan content for and the format of each social network and give balanced responses to its different stakeholders at all times. Furthermore, universities must perform market tests and monitor the results on each platform, that is, implement a system of quality control for each social network and act quickly to modify any content or format in case of negative or unwanted effects. In other words, the continuous improvement of the university's performance on social networks should be promoted.
- *Assigning responsibilities.* Universities must assign responsibility for the management of social networks. Among other functions, the individuals assigned to this task must work in coordination with university management in order to decide the university's strategy and its development. These teams must work together with the various interest groups to identify their needs and demands regarding the design, operation, and use of social networks.
- *Technological scanning and investment.* The team responsible for the management of social networks must invest in the necessary technological resources (e.g., WiFi) and offer training on how to use social networks to the different interest groups of the university. Thus, universities must provide the technological bases that are necessary to facilitate and maximize the use and value of social networks. This technological "scanning" should be done proactively in order to identify new digital trends and evaluate the capacity of each social network to provide benefits to current and potential university community members.
- *Measurement of results.* Universities should measure the impact of social networks in relation to their objectives. Thus, for example, metrics such as the number of "followers" and "retweets" can be tracked to measure the interest generated by any published content. Moreover, extensive studies can be carried

out aimed at asking students which social network provided useful information or generated more interest on a topic.

Operational Agenda: Parameters of Quality on Social Networks

Given the great diversity of social networks, there is no ideal model for the management and design of content. However, social networks are digital platforms that, therefore, require features similar in nature to other digital scenarios. From the results obtained in different studies on the functioning of social networks and from the perspective of service quality (Ellahi and Bokhari 2013; Rauniar et al. 2013; Wu et al. 2015), and some reflections on the proposed strategic agenda, a series of important recommendations for this model are proposed:

- *Design dimension.* Legible format, ordered structure and distribution, logical and intuitive operation, the presence of navigation elements (menus, navigation bars, etc.), and an attractive and modern design.
- *Content dimension.* Relevant content, updated information, entertainment (games, contests, etc.), and diversity of multimedia formats.
- *Service dimension.* Guarantees of security and data protection for users, education and maintenance regarding the ethical behavior of users, support for doubts and problems regarding use of the platform, and quick response times.
- *Relational dimension.* Continuous adaptation to the needs of users, proactive attitude to boost the network and capture the attention of users, management of positive and negative comments, and transparency.
- *Integration of social networks dimension.* Appropriate choice of messages on different social networks and consistency (at the content level) between messages displayed on the various platforms (corporate website, Facebook, Twitter, etc.)
- *Value dimension.* Analysis of comments on the social network to make improvements in online and offline management, innovation on technological resources, design new products, and services at university.

Final Reflections

Currently, platforms such as Facebook, Twitter, and ResearchGate – among others – play an important role in numerous universities. The diverse interest groups represented by universities (teachers, students, administration and service personnel, etc.) can participate in networking on the social networks that have a presence at the university and gain access to a large range of multimedia content (academic information, offer of services, news, videos, etc.), as well as help to build new knowledge (opinions, providing news, expanding information, sharing experiences, etc.).

We can speak of “network of networks,” where the digital space becomes a collaborative, transparent, and enriched environment and one network leads to another (e.g., a Facebook post appears on Twitter). Furthermore, the same interest group can use several social networks, for example, when the academic staff uses different social networks for different organizational roles. Subsequently, universities must provide multi-level online scenarios as a map of social networks. With this, the various members of the university community can interrelate in virtual spaces in a dynamic, interactive, and continuous way according to their particular interests – mainly, on academic, scientific, business, cultural, and social issues.

Social networks contribute toward strengthening the image of the university and the development of its mission and organizational strategy. Indeed, social networks favor an open, multicultural, committed, innovative, and globalized university model, which influences the wording of the “raison d’être” of the institution and its values and expectations. In addition, these platforms improve the effectiveness and efficiency of universities, that is, they allow them to fulfill their objectives with the maximization of available resources. Moreover, social networks can contribute to improving the strategy and future functioning of universities.

From the resources offered by each social network, universities should, as far as possible, create spaces that are logical, ordered, intuitive, and safe.

They must also provide content of interest and allow users to create new content. Furthermore, universities must be receptive to all kinds of ideas, suggestions, and comments that are expressed on social networks, using constructive and positive language. Above all, the management of social networks must create value for its users, for example, by improving the university's academic and service offerings. Together, this paper presents a model that to provide a frame of reference for university management in the context of social networks.

Summary

In terms of economic, social, and cultural impact, few digital innovations have been quite as influential as social networks in recent times. These platforms are an ideal channel of communication through which to publish, share, and comment on content in various formats, creating communities of users in the process. In this way, social networks can contribute toward consolidating a constructive, participatory, and socially oriented university model.

The present work presents a model of university management of social networks that starts from a series of basic premises on which to develop a strategic and operational agenda. The basic premises correspond to the principles that characterize social networks and that should be included within their set of organizational values. Based on these principles, in the strategic agenda, the university must establish how to include social networks in its strategic and operational management. In this regard, social networks are not only a technological resource that supports the performance of the university but should also be included in the formulation of the institution's strategy at all levels (academic, services, relations with other universities, relations with society in general, etc.). The operational agenda proposes a series of recommendations to increase the quality of the browsing experience on social networks, both in format and content.

Introduction

The increasing use of computing and mobile technologies over the past 15 years has had a dramatic impact on both personal and professional lives. This rapid growth in technologies has also increased the demand for skilled software developers, and this demand is increasing on a global scale. A report from the United States Department of Labor (2015) states that employment in the computing industry is expected to grow by 12% from 2014 to 2024 which is a higher statistic than the average for other industries.

Despite this demand for computing graduates, it is recognized that a significant barrier for increasing the numbers of computing graduates lies in the inherent difficulty of learning how to develop quality software. This difficulty has resulted in significant failure rates globally in computer science programs (in comparison to other disciplines) over the past decade and which speak to a lack of competency being achieved by

students particularly in software development (Watson and Li 2014). Running in tandem with failure rates, there are also significant issues associated with the retention of undergraduates in computing programs (Petersen et al. 2016). Both of these issues have resulted in a very active research community in computer science education at third level, specifically at the first year level, as this is where many of the issues with retention and competency first occur.

If students are to become competent in software development, it is widely accepted that teaching students how to problem solve and generate solutions in a structured way is vital in enabling them to develop proficiency (Morgado and Barbosa 2012). Being able to solve problems that require a software solution in a structured way implies the use of a software development process. This is a mechanism which informs a software developer of the steps and stages involved in developing quality software from initial analysis to final design and implementation (Boehm 2006). However, even though there are many processes available for experienced developers (e.g., *Agile* processes), very little work has been carried out on developing appropriate processes for first year, third level learners who have little or no prior programming experience (Caspersen and Kolling 2009). The reason for this deficiency is due to the problematic nature of teaching software development to inexperienced learners as using a software development process assumes that the learner has preexisting programming knowledge so they understand computational constructs such as iteration and modularity. This makes the use of formal processes difficult for educators of introductory software development courses and produces a conundrum of how to support students in the use of development processes in the absence of such programming knowledge. This presents a vacuum for educators which means that the process of developing software solutions is typically taught very informally and implicitly on introductory courses at third level (Coffey 2015). In practical terms, this means that analysis and design is often treated very casually on such courses with the focus instead being on the teaching of syntax without providing adequate strategies to

formulate designs for programming problems. In such an environment, it is natural then that the primary focus of such courses gravitates towards the teaching of programming concepts, with the topic of development process coming later in the course or in later years.

The problem with this focus is that it does not support students in the acquisition of good development habits and practices as novices have a natural inclination to focus on the surface features of a problem in order to fit what is known about the problem into their existing knowledge. This means that novice developers will often jump straight into implementing some aspect of a solution without any planning because they can find it difficult to separate ideas for solutions from the implementation of those ideas (Kokotovich 2008). This can lead to the adoption of maladaptive cognitive practices in software development (e.g., coding by rote learning) which can be very difficult to unlearn and can ultimately prohibit student progression in the acquisition of software development skills (Huang et al. 2013). It has also been found that poor practices in planning and designing software solutions acquired in the first year can persist even to graduation (Loftus et al. 2011). Therefore, it follows that if a software development process is incorporated explicitly in an appropriate way into introductory courses to scaffold students in software development, this could limit the development of such maladaptive practices. A systematic process should not only help those students who have fundamental problems arriving at a solution but should also improve the quality of solutions for all students. This view is echoed by De Raadt et al. (2009) who suggest that students will perform better at software development when they are taught explicit strategies for design rather than such strategies being an implicit part of the syllabus.

In order to understand the characteristics of software development processes both in industry and in third-level education, the following sections will examine the most common processes used in both domains before suggesting some core components that could be used in the generation of an educational software development process aimed at novice, third level learners.

Software Development Processes in Industry

Research into the production of software development processes for commercial use has been a robust and very important area of research and growth for the software development community for the past 30 years (Pathak and Saha 2013). Having a well-defined process ensures that software can be developed in a systematic fashion where there is traceability from problem specification right through to final work product; all work can be measured and thus improved. There are many different software development processes available for use in the software industry but they all follow the basic stages outlined in Table 1 albeit in different configurations and execution.

Two principal categories of process have dominated the software industry over the past three decades. The first category is the *Software Development Life Cycle (SDLC)* process. This is the oldest and most generic category of process which executes the stages as outlined in Table 1 in a strict sequential fashion since its inception in the 1980s. However, in the intervening years, there have been many improvements and

Software Development Processes Designed for First Year Computing Undergraduates, Table 1 Core stages of a software development process

<i>Preliminary analysis</i> – This first stage allows for an initial investigation of a problem in order to discover the principal outcomes and goals of the problem. This investigation is typically coupled with a feasibility analysis in terms of costs, time, and personnel
<i>Requirements definition/systems analysis</i> – Once the problem has been deemed feasible, this stage investigates what needs to be done in order to solve the problem. This will involve understanding the functional requirements to solve the problem
<i>Design</i> – This stage focuses on designing potential solutions for each of the requirements
<i>Implementation</i> – This stage uses the work products from the design stage as a guide to implement software
<i>Integration and testing</i> – In this stage, individual software units are tested and integrated into a final working solution
<i>Maintenance</i> – This final stage involves continuous improvement of software after deployment

amendments made to this process. This has included the realization that due to the complex nature of eliciting user requirements, gathering fixed requirements up-front that then cannot be changed or improved later in the project is unfeasible and can lead to unusable systems. A more effective route is to allow steps to be retraced to allow for evolving requirements.

The second principal category of processes is Agile which is arguably the most popular and widely used methodology in current commercial software development (Bustard et al. 2013). Agile emerged in the 1990s as an attempt to more formally deal with higher rates of change in software requirements as well as customer expectations and the high perception of project mismanagement that existed at the time. The main characteristics of processes based on this category have their origins in iterative and incremental development and involve breaking development work into small increments to minimize the amount of up-front planning and design. Iterations are short time frames that typically last from 1 to 4 weeks and involve a team including a customer representative(s) who work on all stages of developing the increment from planning through to testing. From an educational perspective, it has been found that the nature of fast, iterative development of Agile makes the inclusion of such processes (such as XP, Scrum) into third level curricula more appropriate to students in their final or penultimate year of undergraduate study where they have a degree of experience and proficiency in software development.

This section provided an overview of software development processes used in the software industry; the next section examines the use of software development processes at third level.

Software Development Processes in Third Level Education

It is only natural that evidence-based processes based on SDLC and Agile would be considered appropriate for use in third level educational courses. However, as was established in the introduction to this entry, the use of such processes

presuppose a thorough understanding of standard programming constructs which inexperienced third level learners will not have. Therefore, it is clear that processes aimed at this cohort of learners must take this lack of experience into account while also incorporating the basic stages of software development (see Table 1).

In examining the literature for software development processes aimed at inexperienced third level learners, it was found that despite the wealth of established software development processes aimed at experienced developers working on large projects, there are comparatively few available for introductory, third level computing courses. This relatively small number of processes is most likely due to the difficulty of juxtaposing a lack of programming experience with the use of a software development process. Table 2 provides a summary description of some of the more widely publicized of these educational software development processes.

One noticeable feature of the processes described in Table 2 is their specific focus on a particular aspect of the process. For example, the STREAM process (Caspersen and Kolling 2009) focuses on design in an object-oriented environment; the P³F framework (Wright 2012) also has a focus on software design and aims to arm novice designers with expert strategies; the process by Hu et al. (2013) has an emphasis on generating goals and plans and converting those into a coded solution via a visual block-based programming language; POPT (Neto et al. 2013) has a focus on supporting software testing; and Morgado and Barbosa's process (2012) aims to support students through all developmental stages with the use of template forms coupled with an instructor supplied prototype to aid understanding of the problem. These examples suggest that there is a gap in the research for a process aimed at novice learners that supports all aspects of developing software solutions with a focus on the learning and utilization of developmental constructs and problem-solving skills.

The following sections build the case for an educational software development process by highlighting the principle requirements of such a process.

Software Development Processes Designed for First Year Computing Undergraduates, Table 2 Educational software development processes

Software development process	Description
STREAM – Stubs, Tests, Representation, Evaluation, Attributes, and Methods (Caspersen and Kolling 2009)	This process has a focus on incremental development in an object-oriented environment with Java as the implementing language. It contains six clear stages that allow students to incrementally build up a solution to a problem
P ³ F framework – Principles, Patterns, and Process (Wright 2012)	This process has a focus on design. It uses four elements to allow students employ expert design strategies such as design patterns to ensure they design efficient and sustainable solutions
Programming methodology (Hu et al. 2013)	This process has a focus on the planning stage of development. It uses a five-stage process to facilitate students to create plans and goals for their solution to ensure they fully understand the nature of the problem. Plans are developed using a block-based language similar to Scratch
The Morgado and Barbosa approach to solving programming problems (Morgado and Barbosa 2012)	This process has a focus on planning and design. It contains two stages supplied with rules that allow students fill in template forms to help with their planning. A prototype solution of the problem is supplied by the instructor
POPT – Problem-Oriented Programming and Testing (Neto et al. 2013)	This emphasizes the importance of testing in software development and supplies steps for planning and undertaking tests

A Framework for an Educational Software Development Process

Prior to the development of a software development process, it is important to formulate a framework on

Software Development Processes Designed for First Year Computing Undergraduates, Fig. 1 From learning process to software development process. (Source: Author)

which the process will be based. The role of this framework is to guide the context and content of the resulting software development process.

The first issue that requires attention is in understanding the context in which the software development process will be used. This is an environment where freshman, undergraduate students typically have little or no programming experience and are learning how to develop software solutions in a systematic fashion. This raises an interesting question – should students be taught how to program first and then be introduced to a software development process or should programming concepts and skills be taught as part of a process? This research takes the latter view as teaching students how to program independently of process runs the risk of students developing poor development habits that become ingrained by the time they learn a process. Therefore, the software development process should scaffold so that it inherently encompasses a learning process which can slowly fade as students gain expertise of developmental concepts, practices, and grow their self-efficacy. The relationship between learning process and software development process is visualized in Fig. 1 where Maslow’s (1970) four stages of learning model are used to timeline the progression of learning.

At the start, the learner is categorized as an unconscious incompetent who does not know what they need to know so the software development process is heavily scaffolded as a learning process where the students are guided to use the software development process to fully solve a suite of problems that are appropriate to each

stage of their learning. By the time the learner has gained experience of the concepts and practices, the scaffolding of the learning process will be removed to allow the learner continue to use the software development process in solving new and more complex problems as they expand their learning and continue their journey towards becoming unconscious competents.

Once the context of the environment is understood, it is important that the details of both the learning process and software process (see Fig. 1) are fully teased out.

A Learning Process

A learning process should contain the *knowledge*, *skills*, and *attitudes* that constitute the essential learning elements required to develop software solutions as well as encourage a positive mental disposition for learning.

In order to identify the *Knowledge* component of the process, it is important to state that this process should be applicable to a variety of imperative, commercial languages typically taught in introductory, third-level courses. Therefore, the content in the process should not be language specific but should capture the essential content that forms the basis of such languages in a generic fashion. Such content typically includes:

- 1. The declaration of variables and sequential flow using these variables (e.g., input/print/assignment)
- 2. Nonsequential flow of statements including conditional and iterative constructs
- 3. Modularity to enable code optimization and reuse
- 4. Object interaction (if the development paradigm is object oriented)

While these four areas would make up the essential knowledge component of any learning process, it is worth exploring a mechanism that that can provide a lens into the student learning liminal journey (both cognitive and affective) with the aim of guiding them into becoming more proficient and confident at solving programming problems. The theory of threshold concepts can provide such a lens.

Threshold concepts (TCs) have been proposed as a way of characterizing the progression of learning by students in any subject area. Land et al. (2005) suggest that within each subject, there are certain concepts that are difficult to grasp and are troublesome but once mastered, they act as a portal that can open up a new way of thinking within the subject area that is transformative and irreversible. They also state that “crossing the threshold” to understanding these concepts is a necessary step if students are to advance and become proficient in the subject area. In examining the research carried out into TCs for computing, it is clear that there is not a consensus on a list of TCs for this area and the principal research into identifying TCs in computing have been mainly carried out by a group of European researchers (Sanders and McCartney 2016). In examining all of the published research on the identification of TCs for computing, there are two concepts that emerge as having consensus to date. The first is *program dynamics* meaning having a mental understanding of the dynamics of state and program/algorithm execution and the second – only relevant in an object-oriented paradigm – is *object behavior*. It can also be argued that *object behavior* is a subset of the concept of *program dynamics* (when the development paradigm is object oriented) as understanding object behavior requires having a mental model of the behavior and state of “live” objects in execution.

Therefore, the declarative knowledge for this learning process will focus on the four essential concepts outlined at the start of this section but will teach them through the lens of program dynamics. These four concepts are now relabeled as threshold concept stages, are coded as TC1 to TC4, and are summarized in Table 3.

Software Development Processes Designed for First Year Computing Undergraduates, Table 3 Threshold concept stages for learning process. (Source: Author)

Threshold concept stages
TC1: State and sequential flow
TC2: Nonsequential flow control
TC3: Modularity
TC4: Object interaction

In order to identify the *Skills* component of the learning process, students must be taught appropriate problem-solving skills that will allow them to solve problems. Computational thinking (CT) is an approach to problem-solving that aims to utilize the strategies undertaken by expert software developers as a mechanism to solve problems in any discipline that require a computational solution. CT was popularized by Jeanette Wing (2006) in her seminal paper although the phrase was originated by Seymour Papert in the context of using the affordances of computer-mediated instruction to help students experiment with – and understand – mathematical concepts. There is a clear distinction in the literature made between CT and programming in that even though programming is a key route to enable CT, the process of CT itself may be applied to solving problems that do not involve a programming solution. The research interest in CT has grown as a result of our ubiquitous technological environment. In such an environment, it is argued that CT is a basic literacy which should be an integral part of the educational process across all educational levels and disciplines where students of all ages can become adept at seeing how problems can be broken down and solved with appropriate computing tools in innovative ways. As a result, there is a lot of active and very interesting research into the teaching and assessment of CT. Much of this research is aimed at first and second level education often in the context of block/visual languages (such as Scratch, Alice, AgentSheets) and game-based learning which is used to teach CT skills to all levels including third level. At undergraduate level, CT is also being researched as a mechanism to introduce computer science skills to noncomputing students. While there is no doubt that the key skills associated with CT are an inherent part of computer science courses which principally teach commercial, imperative languages, there is little evidence in the literature to show that the advantages of CT are being explicitly exploited and incorporated into mainstream introductory software development courses at third level. This suggests that there is an opportunity for computing courses to

explicitly mine the affordances of CT to support introductory education at third level.

Given that research into CT has only been active for the past decade, the topic is still relatively immature and so there is yet little agreement on what constitutes a detailed definition of CT or how it can be assessed. From examining the literature, seven principal skills most commonly cited are: *applying abstraction; data analysis and representation; problem decomposition; evaluating solutions; pattern recognition; generating algorithms; modelling and simulation*. Other concepts such as *iteration, recursion, and parallel thinking* are also suggested by Wing (2006). It is the contention of this author that *iterative* and *recursive thinking* are concepts which form part of declarative knowledge which is then made procedural by the CT skills of *writing algorithms, modelling, and simulation*. It is also felt that *parallelism* is a concept which is too advanced for novice computing students studying in the context of imperative, textual languages. These seven skills are coded as CT1 to CT7 and are summarized in Table 4.

Finally, in order to identify the *Attitudes* component of the learning process, it is important to acknowledge the impact of affective learning on developing students’ belief systems, emotions, and attitudes. One affective factor important in determining the success of students in a software development course is the students’ belief in their self-efficacy in the subject (Bandura 1994). Self-efficacy is a judgment by a person of how capable they are of successfully carrying out a task which influences their choice of activities, the amount of effort they expend, their persistence in

Software Development Processes Designed for First Year Computing Undergraduates, Table 4 CT skills for learning process. (Source: Author)

Computational thinking skills

Software Development Processes Designed for First Year Computing Undergraduates, Fig. 2 Elements of a learning process required for an educational software development process. (Source: Author)

overcoming difficulties, and ultimately their performance outcomes. Individuals with strong self-efficacy believe that they can succeed in challenging tasks which means that they are motivated to attempt such tasks and have confidence as they begin the journey to completing the task. Studies in the theory of self-efficacy have found it to be malleable meaning that it can be changed particularly in introductory courses to improve performance. Suggested routes to improving self-efficacy include supplying clear instruction of the strategies required at each step of the problem-solving process, presenting mastery models to demonstrate how to carry out a task competently and confidently, supplying coping models to make explicit the difficulties students can experience in carrying out software development and giving useful and positive feedback. While a strong belief system can push learners to exceed their expectations, it is also important that they do not have a distorted view of their actual capabilities. Therefore, it is important that students are able to reflect accurately on their learning and experiences to allow them understand what they know, what they do not know and ultimately gain accurate self-efficacy in their abilities. Students should be helped develop their metacognitive skills to enable them to monitor, evaluate, and regulate their own learning strategies which is an important ability for the development of independent learning, encouraging students to take more responsibility for their learning (Sheard et al. 2013). Therefore, giving students an awareness of their self-efficacy through metacognition and providing an environment to promote a growth in

self-efficacy is a guiding force in the learning process.

In summary, this learning process suggests basing the knowledge required on the use of threshold concept stages, the skills are based on computational thinking skills, and the (student) attitude should result in increased self-efficacy in software development. A diagrammatic overview of the learning process is given in Fig. 2.

In Fig. 1, it was seen that the proposed educational software development process has both a learning process and a software process. This section explores the principal suggested components for the learning process, and the next section examines the principal components of the software process.

A Software Process

In understanding the requirements of the underlying software process in Fig. 1, one of the more appropriate strategies for general problem-solving that can be adapted to a wide variety of educational contexts – including programming – is found in Pólya’s *How to Solve It* (1957). This text postulated that there are four main stages to problem-solving (where the context was mathematical problem-solving): *understanding the problem, making a plan to solve the problem, carrying out the plan, and reflecting on the success of the plan*. The strategy suggested for this software process is a basic adaption of this four stage model.

1. *Understand the problem* – The learner aims to achieve an understanding of the nature of the

problem as well as the goal of the problem. When a learner understands and internalizes a goal, they set expectations that can help push and motivate them to learn the new skills required to achieve the goal. In this way, learners can begin to recognize that with effort, their learning curve can increase.

2. *Break down the problem into task components* – This stage requires the learner to break the problem into a hierarchy with levels of tasks and subtasks which constitutes an analysis of the problem (“What do I have to do?”). These subtasks will be articulated to indicate what must be done as opposed to articulating how it is going to be done. Similar to step 1, there will be a metacognitive aspect to this step to encourage learners to think about what they are doing and why they are doing it. It is important that there is a mechanism for the learner to organize tasks in a visual and sequential way.
3. *Design (and code) each task* – It is recognized that as learners become more proficient and as they start to encounter similar tasks in problems, an automation of procedural knowledge will begin to occur. Therefore, not all tasks will need to be designed so metacognitive planning will need to occur to ensure tasks can be marked as requiring further design or not. For each task that does require a solution to be

designed, this design should be represented graphically in a format that can be directly traceable back to the hierarchy of tasks in stage 2. The generation of the designs and their associated program code will be carried out in an iterative and incremental fashion with each interment tested and integrated into the final solution until the entire problem has been solved.

4. *Evaluate your performance* – This final stage tests the final programmed solution and gets the learners to reflect on their performance overall as well as their performance in the individual stages. This will encourage learners in their meta-cognitive abilities to regulate their own learning and move from being novice to expert developers.

The process – summarized in Fig. 3 – will also be supported by an Agile philosophy to guide best practice development practices especially in its use of incremental and iterative development. It is assumed that each stage is iterative and that users can step forwards and backwards between steps as they refine and evolve their solution.

Now that the learning process and software process from Fig. 1 have been explored, these can be combined to form an operational software development process aimed at first year undergraduates.

Software Development Processes Designed for First Year Computing Undergraduates,

Fig. 3 Stages of software process. (Source: Author)

CADET: A Generic Educational Software Development Process

When deciding on an appropriate name for the process, the term “computational design thinking” was examined. This term is currently used in architecture and construction as that industry has moved from computer-aided-design (CAD) to more sophisticated computational processes. It refers to the fact that the affordances of advanced computer technology are creating new types of design processes and new ways of thinking about design. In the context of this research, the term is extended to “*Computational Analysis and Design Engineered Thinking*” (CADET) to refer to the art of software development processes being computer mediated so that the stages of the process produce concrete visual artifacts with which learners can experiment, evaluate, and reflect on as part of their learning. These artifacts should be minimal and should adopt a “just enough” approach to allow learners arrive at solutions in a supported fashion. Therefore, the CADET approach is about learning computational concepts and skills in a computational thinking focused problem-solving environment where the final work product is a verified program. A summary of this process can be seen in Fig. 4.

At the scaffolded learning process stage, learners will work in pairs and will be taught the four threshold concept stages (TC1–TC4) which make up the declarative knowledge. This learning aspect of the software development process is represented as a ladder of learning where each concept is ordered and is a prerequisite to learning the next concept. Each concept is taught via instruction and the computational thinking skills required to utilize the concept are acquired by learners solving a suite of problems using the four-stage software process which is supported by an Agile philosophy. Each of the four stages of the process will use a subset of the computational thinking skills.

Once a (threshold) concept stage is mastered, focus moves to the next concept and the software process is reactivated for another suite of problems relevant to that concept. Once all four threshold concept stages have been taught and practiced, learners will continue to use the four-stage software process with associated computational thinking practices as the basis for software development. This makes this process suitable for learners that have and also that do not have prior programming experience. The software development process is augmented by an online support tool (see Fig. 5) which provides a platform to provide learners with problems to solve for each threshold concept stage as well as diagramming

tools to support their analysis, design, and reflective work.

An external development environment will be used to support the coding stage of the process. While it is expected that learner's self-efficacy will grow and wane as they attempt to solve problems, it is hoped that the scaffolded environment will allow the learner's self-efficacy to generally grow in tandem with their knowledge (identified as A1 in the vertical arrow beside the ladder of learning in Fig. 4). This will be measured by learner reflection.

Each of the four stages of the software process is now described in more detail.

Understand the Problem

In this stage, learners will either be provided with a problem specification (that is appropriate to the threshold concept stage if they are using the learning process) or they can supply their own problem specification and will be invited to articulate their understanding of the problem. This is achieved by

employing the computational thinking skills of functional abstraction to generate a high-level summary of the problem (with its principle goal and outcomes) and pattern recognition to see if it is similar to any previous problem the learner may have solved. This high level summary is recorded in the support tool.

Break into Tasks

This stage employs the computational thinking skills of decomposition to convert the high-level summary and specification from stage 1 into an intermediate set of constituent tasks and to further refine those tasks into more basic tasks. In order to make this stage visual, learners will brainstorm tasks using a mind map with their summary of the problem being the central task (see Fig. 6 for an illustrative example of such a mind map). Mind mapping has been shown to be successful in helping learners to brainstorm (Ackerman and Simmons 2016) and specifically in analyzing software solutions (Li et al. 2015). This author has

Software Development Processes Designed for First Year Computing Undergraduates, Fig. 6 Example of a CADET mind map. (Source: Author)

had experience of successfully using mind maps with inexperienced student developers.

The map will be refined into ordered tasks and subtasks. Abstraction will be used by the learner to articulate a trace backwards and forwards from the high-level summary from stage 1 into this stage to ensure consistency between the stages. Pattern recognition will be employed by learners to identify any tasks that have been utilized before in other problems (these will be marked with a pattern symbol). Finally, learners will continually evaluate their analysis of the problem and validate their proposed task list though tracing. They will make decisions about tasks that can be immediately converted into program code (color coded as green), require further design (color coded as orange), and those tasks of which they are unsure and which require assistance from their instructor (color coded red).

Design and Code

This stage employs the computational thinking skill of decomposition to take a task (colored

orange) and generate an algorithm represented as a flow chart for the task. This will also involve the skills of data representation and algorithm writing to represent the computational steps needed to represent a task solution as a flowchart with a level of detail to make it easy for the task to be converted into program code. Any task that has been color coded as green in the mind map can be programmed immediately with patterned tasks reusing or adapting existing designs. All tasks will be designed, coded, and evaluated in an iterative manner until correct and then reintegrated into a growing final product. Abstraction will be employed to ensure learners can oscillate between tasks identified in the mind map and any associated designs and code to trace their understanding at each functional and data abstraction level and ensure consistent mapping between stages.

Evaluate Solution and Learning

This final stage of the process allows the learner to reflect on their solution from start to finish and

employ abstraction to zoom in and out of their solution and understand it at the various functional and data abstraction levels and also be able to reconcile transition between those levels. Critiquing will be employed by the learners to see if any aspect of the solution could have benefited from using analysis, design, or coding artifacts from previous problems. Finally, the learner will be required to articulate what parts of the problem they were able to solve, what parts they either did not solve or found very difficult to solve, and what they need to learn or revise before moving on to the next problem. They should also be able to give a star knowledge rating to reflect the state of their knowledge in each of the computational thinking skills to help them reflect on their skill level.

When the process is being employed solely as a software development process, learners will be able to use both the process and associated tool by providing their own specification for a problem and then working through each of the above stages to systematically develop their final solution. This CADET process is currently being used and evaluated in this author's home institution.

Conclusion

Despite the recognized importance of software development processes both in software industry and in education, there is a need for more research into the provision of appropriate software development processes aimed at freshman, undergraduate computing learners in a context where learners predominately have little or no prior programming experience. The reason for the scarcity of such processes is due to the problematic nature of teaching software processes to novices. A software development process gives guidance to developers in the development of software solutions from analysis through to final product, but it is assumed that the developer has preexisting programming knowledge. This makes the use of such processes difficult for educators of introductory software development courses and produces a conundrum of how to support learners in the use of development processes in the absence of programming knowledge. In such an environment, it is natural that the focus of such courses will

gravitate towards the teaching of programming concepts first with the topic of development process coming later in the course or in later years. The problem with such a strategy is that it allows learners to potentially develop maladaptive cognitive practices which can prohibit learner progression in such courses.

This entry presents some of the most common development processes used in industry and in introductory third level education and makes the case that educational processes must take into account learners' varying degrees of prior programming experience. An educational development process is suggested which utilises the affordances of computational thinking to create a software development process that encompasses a learning process. The process combines current research into computational thinking as a problem-solving process underpinned by the focus of threshold concepts to support learners who are learning how to develop software solutions from problem specification through to the final tested product. The aim of the process is to provide scaffolding to learners as they learn how to develop software in a systematic fashion. This scaffolding will fade as learners become more experienced allowing them to continue to use the process as they grow their experience.

It is the contention of this research that the provision of such a process – while not a silver bullet to eradicate all of the problems learners experience in learning software development – would provide a structured and scaffolded environment to directly address the maladaptive cognitive habits that learners often form and find hard to unlearn. In any event, it is clear that more research into educational software development processes is needed in order to tackle proficiency and retention problems in undergraduate software development programs.

Introduction

The use of new technologies and the acquisition of technology-related competences have been widely considered relevant and even indispensable for participation in a modern knowledge and information society (Anderson 2008; Jordan et al. 2016). Recent developments have led to the emergence of new challenges for schools and school systems, resulting in an ever-growing need for students to develop new forms of relevant skills like digital literacy or computer and information literacy (Drossel et al. 2017). In view of the necessity to meet these challenges, tablet computers are seen as providing a variety of opportunities as mobile learning devices. International studies based on an increasing dissemination of tablet computers around the world have found tablet computers to have a positive effect at various levels of student learning. The effects include individual dimensions such as cognitive and metacognitive competencies (e.g., learning strategies and efficacy) as well as affective aspects such as motivation and also inter-individual collaboration and collegiality (cf. Li et al. 2010). With tablet computers combining the benefits of built-in cameras, microphones, and post-processing software for recorded media and multimedia working tools in one product, they also allow for the individualized installation of so-called applications in order to expand their range of functions at will (cf. Nguyen et al. 2007). Tablet computers are further considered to be advantageous due to their fast applicability, their direct and user-friendly handling, as well as their extended battery service life and resistance to system failures or manipulations (ibid.). With regard to their pedagogical use, tablet computers are assumed to improve students' individual advancement, enhance the flexibility of teaching and learning arrangements, establish collaborative working processes, and assist in comprehensively supporting students' media competence (cf. Enriquez 2010; Geer et al. 2017; Katzan 2015; Soffer and Yaron 2017; Woloshyn et al. 2017).

While research focusing on tablet computers for different educational purposes is increasingly common, the frequency of use by school subjects as well as the relationship between the use of tablet computers and skills such as digital literacy or

computer and information literacy has so far not been a key research interest. This research gap is elaborated on in this contribution using quantitative and qualitative data derived from the so-called TiGer project (2014–2017; the German acronym TiGer stands for “evaluating and reflecting use of tablet computers at upper secondary schools”) conducted at a German upper secondary school. This data set provides current in-depth data from a research project with a quasi-experimental longitudinal design. Referring to the abovementioned research gap, the aim of the study is to examine the extent to which the availability of tablet computers impacts their use in class, what level of computer literacy students have, and how this develops over time. In so doing, the overall issue of the role of tablet computers with regard to students' computer literacy is examined.

In the following, the central constructs, which are the basis for the tests applied to the students, are explained from a theoretical perspective. Furthermore, insights into the current state of research are presented and lead to the research questions addressed. Following a more detailed description of the design of the study, the research questions are answered and finally discussed on the basis of the findings of the study.

Theoretical Allocation of the TiGer Study

The relationship between the use of ICT (information and communication technology) and educational outcome is described in many theoretical models of school effectiveness (e.g., Biagi and Loi 2013; Law et al. 2008). One empirically elaborated model referring to computer literacy has been developed in the scope of the IEA (International Association for the Evaluation of Educational Achievement) study ICILS 2013 (International Computer and Information Literacy Study) focusing on to computer and information literacy (CIL) (Fraillon et al. 2013; see Fig. 1). With regard to the framework, the use of ICT is understood as a factor at the process level being part of a set of school and classroom factors. The model taken from the international study ICILS 2013 thus serves as a theoretical basis for the

Students' Computer Literacy and the Use of Tablets in Upper Secondary Schools, Fig. 1 Theoretical model integrating computer literacy and students' use of computers in class (Fraillon et al. 2013, p. 26)

TiGer study; it integrated both students' outcomes and students' use of ICT.

Current State of Research: The Use of Tablet Computers and Computer Literacy

The current state of research will be presented bringing three strands of research together: Firstly, the use of ICT is presented by focusing on tablet computer use in schools and is examined by highlighting the situation in Germany within the international context. In a second step, insights into research with regard to students' computer literacy are provided, starting with a definition of computer literacy as it is understood in the scope of the presented research. The third and last strand brings together research findings on the relationship between computer use and students' achievement in computer literacy.

The Use of Tablet Computers at School and Conditions

Researching the use of mobile technologies in schools went through different phases, especially

when it came to laptop projects (e.g., Warschauer 2007). Research on tablet computer use in schools can be identified as a new wave of researching the use of mobile devices. Understanding schools and classrooms as multilevel systems, framework conditions of using ICT for teaching and learning have to be taken into account in order to understand the pedagogical use of such technologies. From a German perspective, it is particularly striking that in Germany, a traditional concept of IT infrastructure using static computers in computer rooms is still common practice (Fraillon et al. 2014). The use of mobile devices in schools in Germany is limited by the provision of IT infrastructure, and it can be considered distinctly below average in international comparisons and especially in comparison to Germany's neighboring countries (ibid.). According to the data gained from ICILS 2013, IT coordinators and school principals, a mere two fifths of students in Germany (43.7%) attend a school that provides a sufficient number of portable devices that can be carried from classroom to classroom. Close to one fifth of Grade 8 students in Germany (18.0%) report attending a school that follows a bring-your-own-device (BYOD) policy (as compared,

e.g., to 83.5% in Denmark). Furthermore, only 6.5% of upper secondary students reported that tablet computers were available for learning in school (ibid.).

The international comparison in general further showed major differences not only in availability of ICT but also with regard to the use of computers at school. While 81% of students in Australia report using computers at least once a week, only 31% of students in Germany report doing so (Fraillon et al. 2014). Taking a closer look at subject-related use, i.e., the use of ICT in the test language subject (e.g., German for Germany), in mathematics and in foreign language subjects, it becomes evident that only three to 4% of students in Germany report regular (at least weekly) computer use in class. In international comparisons, Germany therefore comes last. Other countries such as Australia or Thailand report a significantly higher frequency of computer use in the abovementioned school subjects (ibid.). With regard to these and other findings, it becomes clear that studies including student achievement tests often do not differentiate between different technologies and their use in the classroom. With regard to the differences in applying the respective technologies – e.g., desktop computers compared to mobile devices – and taking different subjects into account, empirical data is scarce. A survey conducted in the USA on the use of tablets in class, however, assessed the use of tablet computers by school subject, differentiating between English, Math, History/Social Studies, Science, and Foreign Language classes (Pearson 2013). The results show that around half of students in elementary school, middle school, and high school use full-size tablets in class several times a week (ibid.). The findings further indicate significantly higher proportions of tablet use in middle schools, i.e., among students up until Grade 9, with the exception of English classes (ibid.). While the results are available from the 2013 Student Mobile Device Survey, the follow-up studies from 2014 and 2015 no longer include data on the frequency of tablet use by school subject, thus not allowing for a longitudinal comparison. Furthermore, the scope of the data is limited to the US-American educational

landscape, thus not allowing for international comparisons.

Students' Achievement in Computer Literacy

Prior to summarizing relevant findings regarding students' computer literacy, the understanding of computer literacy in this contribution needs to be further clarified. Against the background of the instruments used in the TiGer study, computer literacy is defined from a functional perspective. This functional perspective emphasizes the relevance of including "the knowledge and skills that people need to live satisfying lives, in terms of personal and economic satisfaction, in modern-day societies" (Senkbeil et al. 2013, p. 142). Computer literacy is conceptualized as a unidimensional construct comprising the facets of technological and information literacy (ibid.). The construct is therefore also known as technical and information literacy (Senkbeil and Ihme 2012). The information component is defined as the ability to recognize when information is needed and the ability to locate, evaluate, and use the needed information effectively. The technological component means the underlying knowledge of hardware, software applications, networks, and elements of digital technology (ibid.). Additionally, computer literacy differentiates between software applications (e.g., word processing) and process components (e.g., access) (cf. Fig. 2). Based on these insights, computer literacy can be assumed to be applicable to the use of tablets in teaching and learning processes as tablet computers are considered mobile computing devices. The differentiation between technological and information literacy, which both form part of the aforementioned construct of computer literacy, is also valid for tablet computers.

In efforts aimed at assessing students' achievement in computer literacy in an international context, studies around the world have investigated ICT-related competencies of students based on different understandings of computer literacy examined using a variety of methods. Hakkarainen et al. (2000) in Finland, for instance, used a design that relies on the students' self-reported competencies. While the students performed quite well in mastered text processing,

Students’ Computer Literacy and the Use of Tablets in Upper Secondary Schools, Fig. 2 Assessment framework for computer literacy (process components and software applications) (Senkbeil and Ihme 2012, p. 5)

graphical processing, information networks, and file management, they were not as proficient in authoring tools, desktop publishing, programming, and computer hardware. For Chilean students, Claro and colleagues (Claro et al. 2012) used a performance-based assessment design – the ICTSfL test. The results merely show that the students’ skills related to the use of ICT as consumers exceeded the level of skills related to becoming producers using ICT (ibid.). While the aforementioned studies tend to focus more on the data gathered, other studies from Australia have been used to develop an overall ICT literacy scale using computer-based achievement tests, from which proficiency levels regarding computer literacy have been deduced (cf. ACARA 2012; MCEECDYA 2010). While the Australian studies and all studies mentioned above display a scope limited to a region or country, international comparisons of computer literacy in students were, for the very first time, examined in the context of IEA study ICILS 2013. As a result, students’ achievement in what is described as computer and information literacy in the study showed a great

variation between the participating countries. Grade 8 students in Germany reached an average performance of 523 scale points, statistically not significantly different from the European average (525 scale points for EU countries) but significantly above the OECD average (516 scale points) and the international average of 500 scale points (Fraillon et al. 2014). This finding prompts the question as to where students acquire their competences and in which way the use of ICT in schools can support students’ achievement, including the issue of which particular technologies best meet pedagogical needs and support the acquisition of computer literacy.

The Relationship Between the Use of New Technologies and Computer Literacy
Closer investigation reveals that the role of new technologies in classrooms and their impact on students’ performance have been the focus of research literature over the last two decades (cf. Spiezia 2010). Cox and Marshall (2007) have pointed to the fact that a multitude of factors influences both students’ use of ICT and their

ICT-related skills. The authors mentioned factors such as the quality and depth of ICT use, the observations of students using ICT, and the analysis of students' products. Furthermore, meta-analyses (Li and Ma 2010; Tamim et al. 2011) suggest that there is a positive relationship between ICT use and student achievement in different subject areas. While ICT has been examined with respect to its influence on subject-related achievement such as in mathematics and science, the use of new technologies and its relationship with computer literacy has thus far been investigated to a much lesser extent. Only very recently, Rohatgi et al. (2016) were able to show based on data gathered in Norway that the use of ICT has an indirect impact on the computer literacy of students, the intermediate construct being ICT self-efficacy. Sung et al. (2016) in their meta-analysis have further found mobile devices to be more effective than desktop computers or laptops when it comes to students' learning performance. Focusing again on direct effects, the research interest of this contribution comprises both teachers' and students' use of the aforementioned technologies. As far as teachers' use of computers is concerned, international comparisons show a positive effect on CIL in Germany only, contrarily to Australia, Norway, and the Czech Republic (Gerick et al. 2017). Regarding school-related use of computers by students, international comparisons revealed consistently positive relations. Warschauer (2007), for instance, was able to demonstrate that students attending notebook schools (including primary and secondary schools) learn to access, process, and use information much better while also acquiring skills to integrate this information into written and multimedia presentations. Likewise, an Australian study conducted by the National Assessment Program ICT Literacy pointed out that the school-related use of computers shows a positive correlation with students' ICT literacy competencies (MCEECDYA 2010). The ICILS 2013 international comparison also demonstrated that school-related computer use in most participating countries correlates positively with CIL. Only three countries, including Germany, showed a negative effect (Eickelmann et al. 2014). While some authors regard the

literacy developed through the use of tablet computers to be a new, distinct literacy known as tablet computer literacy (cf. Hergüner 2016), the relationship between school-related use of tablet computers and computer literacy has thus far not been addressed. A meta-analysis of 23 tablet-related studies by Haßler et al. (2015) revealed that while the majority of research reports positive effects of tablet use on student learning outcomes, other research, however, indicates that tablet use may indeed have no effect or may even have negative consequences. The authors conclude that "the fragmented nature of the current knowledge base, and the scarcity of rigorous studies, make it difficult to draw firm conclusions." In-depth investigations are advised (ibid.). Accordingly, Kontkanen et al. (2017) conclude that "[t]he value that iPads add to teaching and learning is difficult to quantify because of the complex and often conflicting factors involved" (p. 1299).

Research Questions

The following research questions can be deduced from the research desiderata described above:

- (I) How often do students use tablets in school? Is there a difference between students in tablet classes and in regular classes?
- (II) What level of computer literacy do students have at their disposal? Is there a difference between students in tablet classes and regular classes?
- (III) Which role does the use of tablets play in this context? Is there a relationship between the use of tablets and computer literacy?
- (IV) To what extent do teachers notice any developments regarding tablet class students' computer literacy?

Methodology

Sample

In order to answer the above research questions, this entry uses the data provided by the TiGer project (*evaluating and reflecting tablet*

Students’ Computer Literacy and the Use of Tablets in Upper Secondary Schools, Fig. 3 Design of the TiGer project

computers at upper secondary schools). This project used expert guidance in the process of introducing tablet computers to Grade 7 students at an upper secondary school (*Gymnasium*) in Germany. Tablet computers were used from the beginning of the 2014/2015 school year. These mobile devices are owned by the students who could therefore also use them outside school. Two out of five parallel classes were fully equipped with tablet computers, while the remaining three classes continued without tablets, hence serving as control groups. The concomitant research involves an elaborate triangulation design of multiple perspectives over a period of 2 years. The focus of this research contribution is placed on a quantitative student survey with three points of measurement. The first data was generated at the beginning of the 2014/2015 school year when the students were not yet in possession of any tablet computers (pretest; Time of Measurement 1; ToM 1). The second data was collected at the end of the 2014/2015 school year, with tablet class students having worked with tablet computers while students from the control group had not (Time of Measurement 2; ToM 2). At the end of 2015/2016 following another school year, the students were tested again (Time of Measurement 3; ToM 3). The project thus offers data from three measurement time points over a period of 2 years (see

Fig. 3). In order to model the longitudinal section, all students who had not participated at all three measurement points were excluded from the analyses. The original 119 participants were hence reduced to 105 students that constitute the sample. 43 of these were taught in tablet classes, whereas the remaining 62 attended parallel classes in which no tablet computers were used and that can hence serve as a control group. Furthermore, the quantitative data is subsequently complemented by qualitative teacher data, which was gathered in the form of open-ended questions in teacher questionnaires (at ToM 2 and ToM 3).

Instruments and Methods

In the following, the instruments (tablet computer use and computer literacy) used in the study will be presented in more detail. Furthermore, the methodological approach will be described and an account given of the need for the complex design of a longitudinal quasi-experimental study design incorporating qualitative and quantitative data.

The use of tablets was assessed in a subject-specific approach for all school subjects. In the following, frequency of tablet use is reported for the main subjects – German, Mathematics, and English. The students’ fourth main subject (French or Latin) was excluded from the analyses

Students’ Computer Literacy and the Use of Tablets in Upper Secondary Schools, Table 1 Results of the exploratory factor analysis of tablet use (German, Mathematics, and English)

	ToM 1		ToM 2		ToM 3	
	Tablet classes	Control group	Tablet classes	Control group	Tablet classes	Control group
<i>N</i>	33	43	41	54	40	53
Cronbach’s alpha	0.968	0.840	0.855	0.832	0.547	0.646
Explained variance	94.6%	77.3%	80.3%	75.3%	55.6%	59.0%

because students from tablet classes and students forming part of the control group were taught together. These particular classes therefore did not use any tablet computers. The four-tier response format ranged from *never* (1) to *every week* (4). The use of tablet computers is regarded both subject-specifically and as a latent construct used for further analyses. The exploratory factor analysis of subject-specific tablet use, which only includes cases in which data for at least two subjects was available, reveals that the three selected items show factor loadings on one factor with a very good reliability for both groups of students at all measurement points (cf. Table 1). The question as to whether significant differences can be detected between the groups will be tested using a significance test for independent samples.

For the purpose of assessing students’ computer literacy, the understanding of computer literacy explained above seems to be appropriate. The tests referring to this concept derive from the National Educational Panel Study (NEPS) in which a computer literacy test for students in different grades was developed (Senkbeil and Ihme 2012). Due to the fact that certain tasks covered by the NEPS test were no longer up to date at the time of measurement – which can be attributed to the fast-paced development of new technologies – these tasks were replaced by corresponding items. Examples of items measuring the different aspects of computer literacy can be found in Senkbeil et al. (2013). As part of this test, the multiple choice items cover both the software application and the process components shown in Fig. 2. The paper-pencil test consisting of 36 tasks (including 30 simple multiple choice and 6 complex multiple choice items) depicts real-

life problems embedded in a range of authentic situations using screenshots.

In order to estimate item and person parameters for computer literacy, a partial credit model was used and estimated in ConQuest (Wu et al. 1997). In a first step, ability estimates were estimated as weighted maximum likelihood estimates (WLEs, Warm 1989) with a metric of 500 and an SE of 100. As the same computer literacy tests were used at all measurement points, the item parameters of ToM 1 are implemented to estimate the item difficulty of ToM 2 and ToM 3. The results show that the items exhibited good item fit. Furthermore, the test showed high reliability for the three measurement points (0.974/0.971/0.972), and the different comprehension requirements support a unidimensional construct. In addition to measuring the students’ competencies, open, qualitative questionnaires were distributed to the teachers responsible for teaching the tablet classes (*N* = 6). This complementary instrument results in a multi-perspective, triangulative design of the study, which is expected to contribute to the second research question addressed by this paper.

Findings

Findings on the Use of Tablet Computers

At the beginning of the school year (ToM 1), neither the students in tablet classes nor the students in the control group used tablet computers in their main subjects (cf. Table 2). The two groups therefore do not show any significant differences. It can hence be established that the starting situation is the same for all students. At ToM 2, after 1 year, as well as at ToM 3, after 2 years, the

results show that tablet class students use tablet computers at least once a week. No significant differences between the main subjects could be observed. As expected, the control group does not show any changes with respect to the first measurement time – the use of tablet computers can still be considered an exception here. The differences between students from tablet classes and students from the control group were all found to be significant.

Findings on Students Computer Literacy

The level of computer literacy that students have at their disposal as well as the extent to which students from the tablet classes and from the control group show differences in terms of their performance will be presented in the following and is shown in detail in Table 3. In order to describe students' achievement, the achievement indexes (WLEs), which were previously transformed to a mean score of 500 with a standard

deviation of 100, are reported with a view to enabling better interpretation of the results. The correlation of the WLEs amounts to 0.685 for the tablet classes and 0.678 for the control group. This suggests that the computer literacy construct remains relatively stable over time.

The average achievement of the students taught in tablet classes before obtaining the devices lies at 472.9 scale points, thereby displaying significantly lower scores in comparison with their fellow students from the control group (520.7 scale points). This result remains in force even after the introduction of tablet computers and repeated computer literacy measurement procedures after the school year. Both the control group and the tablet students attain – on average – the same level of competencies as they did at ToM 1, resulting in the fact that tablet students yet again show a significantly lower average level of achievement regarding computer literacy. However, 2 years after the introduction of tablets in the two tablet classes, changes in performance are apparent although they are different from those expected. On the one hand, the tablet students perform significantly less well than in the 2 preceding years (448.0 scale points). On the other hand, the students in the control group perform significantly higher (539.7 scale points).

Relationship Between Computer Use and Computer Literacy: Students’ Achievement

As explained by means of the theoretical framework model (cf. Fig. 1), a correlation between the use of tablet computers and computer literacy can be assumed. At ToM 1, this correlation is not significant for the tablet classes (at 0.209) but proves to be significant for the control group (at 0.389 with $p = 0.005$). The second measurement time shows a substantially smaller correlation that is not significant in either case (–0.011 for tablet classes; 0.183 for the control group) (cf. Table 4), while by ToM 3, the correlation in the tablet classes increased (0.466 with $p = 0.002$), and the (not significant) correlation in the control group became much lower (–0.043). Overall, the assumed correlation between the use of tablet computers and computer literacy can only be

Relationship Between Tablet Computer Use and Computer Literacy: Teachers’ Perspectives

In contrast to the findings from this performance test, the teachers’ impressions as reflected by the qualitative data gathered from an open questionnaire do indicate an improvement in students’ computer literacy. One teacher, for instance, found that “the students use the tablet more like a tool while the ‘play instinct’ gradually decreases. The exhausting of all of the tablets’ functions is impressive. Information research, the preparing of presentations, drafting of emails and saving documents in clouds has become routine for most [students]. The targeted use of apps also becomes more and more conscious” (Mrs Schmidt, 35 years old, teacher of Arts and Spanish). This reflects the experience of all six teachers, especially with regard to the more confident and conscious use of the new technologies. Individual teachers, however, also point to “alarming” cases, where “girls lacking in confidence” continue to have difficulties using basic applications after 1.5 years of using the tablet computers.

Conclusion

The main focus of this paper was to investigate whether the use of tablet computers in the scope of

a 1:1 setting has effects on students' learning and especially on students' computer literacy. An analysis was performed based on qualitative and quantitative data from a tablet project carried out in an upper secondary school. In this project, two out of five parallel classes (starting in Grade 7) were fully equipped with tablet computers, while the remaining three classes continued without tablets, hence serving as control groups. Data was gathered at three points in time over a period of 2 years, starting with data collection immediately before the tablet computers were distributed to the students.

First of all, the analyses have shown that in line with expectations, the tablets were used on a regular basis in the main subjects after their introduction. Students in tablet classes subsequently used tablet computers on an at least a weekly basis, while the frequency of tablet use in the parallel classes without tablets did not change over time and still corresponds essentially to the category of "never." Hence, it is not surprising that students in tablet classes use tablets in class significantly more often than the students in the control group. This result primarily emphasizes the importance of material resources available to students that constitutes a prerequisite for the implementation of new technologies (Eickelmann et al. 2014).

With regard to the second research question, it can be stated that average computer literacy – as tested using the TILT test – was substantially lower among tablet students than among students from the control group both prior to and following introduction of tablet computers. One year after the introduction of the tablets, there were no changes in levels of computer literacy, and after 2 years, it became apparent that tablet students were achieving lower levels, while the control group was improving. These findings were not to be expected; however, they do appear rather plausible when taking a closer look at the instrument with which computer literacy was tested and its theoretical conception (cf. Fig. 2). Contrary to the findings from this performance test, the teachers' impressions as reflected by the qualitative data gathered from an open questionnaire do point to an improvement in the students' computer literacy. This result shows how

important it is to include the teacher's perspective (see also Eickelmann and Vennemann 2017). According to preliminary findings (teacher, student, and principal perceptions), the software applications used there did not correspond to those that were put to use by the tablet classes. For instance, students did not send emails using their tablets but communicated via specially designed communication applications. Further differences were found with respect to the process components of the theoretical framework model of computer literacy. The way in which tablet students manage information, for example, is completely different from the way it is operationalized in the TILT test. The students used the tablets' cameras to digitalize and save documents – a competency that is not assessed by the instrument. It is, however, worth noting that for the German-speaking world, there is currently no valid and openly accessible instrument available to account for these diverse potential applications that are unique to tablet computers. With development in this area being rather fast-paced – both with respect to software applications and hardware – the designing of a suitable and valid instrument indeed constitutes a major challenge. A further possible explanation for the persisting difference in the level of computer literacy could lie in the fact that students from the control group acquired their skills outside of the classroom. This remains to be verified and could constitute the focus of further analyses.

A third result of this research contribution reveals that the assumed correlation between the use of tablet computers and computer literacy as depicted by the theoretical framework model (cf. Fig. 1) cannot be maintained. The same is true if these results are compared to multiple research findings that have asserted a direct relationship between the two constructs (Li and Ma 2010; Rohatgi et al. 2016; Sung et al. 2016; Tamim et al. 2011). At first glance, this result therefore seems unexpected, while it does support the assumption that the TILT instrument could not measure the competencies as they were acquired by students through the use of tablet computers.

From the teacher interviews (question 4), it becomes apparent that there are indeed positive

effects that result from the use of tablet computers, namely, an increase in motivation and confidence in regard to the conscious and targeted use of new technologies.

While the study documented in this entry only can serve as a starting point – data from the study is not representative either for Germany nor for the focused school form – studies with representative samples (e.g., large-scale assessments) may elaborate on the findings presented in the scope of the TiGer project.

Support for School and Institutional Improvement and Accountability

Dorothy DeWitt and Norlidah Alias
Department of Curriculum and Instructional Technology, Faculty of Education,
University of Malaya, Kuala Lumpur,
Malaysia

Synonyms

[Accountability](#); [Institutional improvement](#); [Institutional leadership](#); [Instructional leadership](#); [School improvement](#); [School leadership](#)

Definition

Support for school and institutional improvement refers to the suggestions and guidelines for institutional leaders to be instructional leaders who are accountable for improving instructional practice and developing human capacity. An instructional leader inspires the institution in achieving a shared vision, develops policies related to the vision, builds a culture of data for decision-making, develops instructors' capacities in technology and pedagogy, and provides the technology infrastructure and strategies for community involvement.

Students' Performance

► [Information Technology and Assessment](#)

Introduction

Administrators, either as heads of schools or managers and governors of higher education institutes, have a prominent leadership role. They influence the condition of their staff's work life, which can in turn influence staff effectiveness and students' achievement outcomes (OECD 2009; Pont et al. 2008). However, technological innovation and recent changes in migration and globalization have changed the expectations of students and their parents and posed challenges to administrators (OECD 2009). Globalization and widespread immigration has resulted in a demand for quality education across national boundaries (MacBeath 2009). Students are holding the institutions and their leaders accountable for improving their performance and demand quality education (MacBeath 2009).

The shift toward new pedagogies for learning with technology and reforms in curriculum, assessment, governance, and financing has begun in education systems in many countries. Educational systems need to be transformed for youth to be equipped with knowledge and skills needed in the changing world (OECD 2009). Hence, the role of the institutional leader also needs to change.

Students today are natives of the imagination age: they use virtual reality and innovative technologies for recreational gaming and communication (King 2016). They demand to be equipped with future skills for future jobs. Skills of creativity and innovation need to be developed among students, and this means more demanding educational programs should be implemented in educational institutions, thus, pressuring administrators to produce excellent students from the system. Parents and other stakeholders have higher expectations and accountability from the institutional leaders on students' performance and return on investment in the school system.

However, our institutional leaders may not be equipped to deal with developing skills for solving problems of the future in the imagination age (King 2016). Most institutional leaders were trained in methodologies suitable for the industrial

age, which are irrelevant for knowledge workers and natives of the imagination age (King 2016; Pont et al. 2008). Hence, some suggestions for supporting institutional leaders to be accountable to their stakeholders are made by developing instructional leadership and inspiring the institution to achieve a shared vision, to develop policies related to the vision, to build a culture of data for decision-making, to develop instructors' capacities in technology and pedagogy, and to provide the technology infrastructure and strategies for community involvement.

Accountability

Institutional leaders are held accountable for their institutions' achievements. Governments and other stakeholders who have invested in education systems require these institutions to be accountable for the monetary input provided. Students also demand a quality education relevant to their future employability for the tuition fees they paid. These demands for accountability is believed to motivate institutions toward quality improvement and attaining high standards (Geijsel et al. 2010). Hence, institutional leaders exercise their leadership by implementing systems of observation, monitoring, appraisal, benchmarking, and targets for accountability within their institutions (MacBeath 2009).

Accountability can take many forms. Accountability to external organizations and other stakeholders requires traditional reporting systems, while internal accountability involves a self-inspection of the organization for continuous improvement (MacBeath 2009). Traditional systems of public accountability, such as elections, can hold central governments accountable for education policy failures (Hooge et al. 2012). However, as institutions are given more autonomy, these traditional systems may not work. Different systems of accountability are needed.

The purpose of accountability should be more than just for the attainment of skills and knowledge. Geijsel et al. (2010) outlines three purposes of accountability: the legitimation of the institution in compliance with laws and regulations;

accounting for the quality of services related to the education provided (effectiveness), value for money (efficiency), equity, or access; and finally for the overall improvement of education (Hooge et al. 2012). Hence, measures of accountability should include effectiveness, efficiency, equity, and access to education, rather than only school or institutional performance.

Types of Accountability

Presently, there seems to be two types of accountability mechanisms practiced. Vertical accountability is a hierarchical concept concerned with enforcement of compliance with laws and regulation. Vertical accountability for school performance uses standardized student testing and public reporting of school performance using measures of student information and characteristics, safety issues, curriculum, facilities and grounds, and teacher qualification (Hooge et al. 2012). This form of performance accountability may neglect measures of essential elements and may compromise the teaching and learning processes when instructors reduce the scope of the curriculum and “teach for the test.” As an example, the majority of OECD countries uses a standardized test as an objective measure of skills and knowledge for school performance accountability (Hooge et al. 2012). The results of the testing are used to monitor and ensure the quality of education. However, this standardized test neglects other important goals of education such as development of social skills, moral values, creativity, and other skills for employability (Hooge et al. 2012; MacBeath 2009).

Horizontal accountability, on the other hand, is nonhierarchical and directed at the processes in which institutions and instructors conduct their professional practice with involvement of multiple stakeholders in the educational processes of decision-making, implementation, and verifying results (Hooge et al. 2012). Denmark, the Netherlands, and the United Kingdom make use of multiple school accountability. Students, parents, communities, and other stakeholders are involved in formulating strategies, decision-making, and evaluation for education for improving of the quality of schools (Hooge et al. 2012).

This multiple accountability seems to reduce the negative effects of school performance accountability and makes schools accountable to students, their parents, members of the community, and the community as a whole (Hooge et al. 2012). Hence, multiple aspects of schooling are taken into account from various information sources. There is now a shared responsibility among students, their parents, members of the community, and the community as a whole, to ensure that the school system is effective and continuously provides quality services.

Technology has enabled data collection and analysis for accountability, to be more efficient. Both vertical and horizontal accountability can be reported when data for accountability is systematically collected. This data, when analyzed for meaningful connections, can be effective in identifying problem areas, strengths of programs conducted, as well as the strengths and weaknesses in students’ knowledge and skills (Tolley and Shulruf 2009). The institutional leader can then employ data-driven decision-making to maximize planning for accountability (Tolley and Shulruf 2009).

Instructional Leadership for School and Institutional Improvement

Research has shown that the primary factor for effective schools and institutions is the professionalism of the leadership. There seems to be a correlation between instructional leadership and students’ academic performance, as well as teachers’ effective instruction (Heaven and Bourne 2016; Leithwood and Riehl 2003).

When some of the models of effective leaders are reviewed, it is shown that the behaviors of heads of institutions, which are establishing a clear focus and high expectations on student learning, providing instructional leadership, supporting teacher autonomy, and developing a conducive culture, have an impact on students’ achievements (Cotton 2003).

By setting directions, having a shared understanding of organization and a sense of identity, as well as monitoring the organization’s

Support for School and Institutional Improvement and Accountability, Table 1 Summary of instructional leadership models

	Cotton (2003)	Leithwood et al. (2004)	Jones et al. (2009)
Inspiring a Vision	Clear vision, goals, and high expectations	Setting directions, shared understanding of organization, its activities and goals	Vision/mission/goals Personnel and budgets Policies and procedures Staff reviews and evaluations Student achievement data analysis
Data for decision-making		Monitoring	Staff reviews and evaluations Student achievement data analysis
Instructional leadership	Observing classroom teaching and feedback Protect instructional time	Offering intellectual stimulation Providing individualized support	Academic intervention Coteaching/team teaching Balanced assessments Classroom walk-throughs Grading Peer review of student work
Capacity building		Providing appropriate models of best practice Beliefs considered fundamental to the organization Capacities and motivations	Individualized professional learning Instructional coaching Mentoring Instructional technology Professional development workshops Teacher observations/study tours
Community's involvement	Shared leadership and decision-making Support teacher autonomy Risk taking for continuous improvement	Distributed leadership: shared, collaborative, democratic, and participative Organizational conditions Extrinsic financial incentives or intrinsic commitment to the welfare of students	Leadership teams Needs assessment/strategic planning Rigor/relevance framework Teacher incentives and rewards Professional learning community

performance and effective communication, a shared, collaborative, and participative leadership is developed (Leithwood et al. 2004). This shared, collaborative, and participative concept of leadership can contribute to the organization's success (Leithwood et al. 2004). The instructional leader who provides intellectual stimulation, with individualized and organizational support, shares models of best practices, and develops capacities and motivates teachers would be more successful (Leithwood et al. 2004).

Instructional leadership would mean having a common vision of good instruction, an emphasis on building relationships, and empowering staff to innovate, provide feedback, and share best practices (Jones et al. 2009; Heaven and Bourne 2016). Jones et al. (2009) also provided a framework of instructional leadership by outlining the practices of instructional leaders.

The review of several established models of effective leaders showed that the important aspects are to inspire a vision, set policies, establish the vision, build capacity building, and involve the community (see Table 1). Monitoring and continuous evaluation through systematic data collection ensures that the standards of the organization are maintained. The instructional leader models the way that teaching should be conducted, and provides capacity building by mobilizing a dedicated team, provides guidance in improving instructional practices, and involves the community at large.

The models of instructional leadership are applicable for both schools and higher education institutions and can be used for implementing a technological innovation such as e-learning. Hence, for this purpose, the leaders of the school and higher educational institutions will be referred to as the *instructional leader*.

Inspiring a Shared Vision

The institutional leader sets the direction for the institution. A shared understanding among colleagues about the organization, its activities, and its goals is required for a sense of identity (Leithwood et al. 2004). Goals which are personally compelling, challenging, and yet achievable are more likely to develop a sense of identity for the project within their work context goals (Leithwood et al. 2004). However, developing a shared vision for a new innovation, example an e-learning initiative, is not a simple task.

The purpose of an innovation is to bring about better outcomes. Hence, it is still very important for the leader to have a vision of the better future to be shared among his colleagues. However, in developing this vision, it is important to be aware of opportunities and emerging future trends, and not be limited to present successes in the implementation of the innovation. Instead, the targets set should not be based on present-day achievements because technology is constantly changing and constantly moving targets (Cavanagh and Thompson 2018).

Developing a Vision

Cavanagh and Thompson (2018) suggest the leader needs to have a strategic and rewarding vision of the future by considering several aspects. The leader needs to be informed of four situations as follows:

- (a) *Here/Now*: The operations in the current situation.
- (b) *There/Now*: An understanding of the successful implementation of technology in other similar institutions in the current situation. This is obtained through collegial exchange and consultations through teleconferences, site visits, and conferences.
- (c) *There/Then*: Global context and trend forecasting. The distant vision which is based on a global long-term perspective at a distance from the immediate context. The New Media Consortium's Horizon Report is published annually for K–12 schools and for higher education and identifies key trends and important

developments in educational technology which can provide the vision for the future (see <http://www.nmc.org/nmc-horizon>).

- (d) *Here/Then*: Leaders should envision how things will be or should be in the local context from the *There/Now* and *There/Then* contexts and implement strategic planning in order to achieve the vision. Strategic planning for technology for learning should be in line with the institution's strategic plan and should also take into account innovativeness.

The successful development of a shared vision considers the current technology in other situations and places, the emerging trends and technologies for the near future, and the vision of senior leaders for the institution in the future (Cavanagh and Thompson 2018). In other words, a leader should constantly be monitoring trends, studying the applicability of a valued outcome in the context of his institution, and evaluating the possibility of successful implementation in his institution by "reading the sign of the times" (Cavanagh and Thompson 2018).

Policies

Policies assist the institution in planning and mobilizing the action needed for implementation of an innovation. Czerniewicz and Brown (2009) define policy as both the formal documentation and the course of action to be taken, which encompasses the allocation of goals, values, and resources. Hence, the intentions of the policy documents must be taken with an examination of existing systems, services, and structures. Czerniewicz and Brown (2009) also differentiate between having a *structured* and *unstructured* institutional policy. A structured institutional policy would have formal support from senior level management as a formal policy document exists, with structures to support the reform policy, such as a support unit for the institution, and a system for the institution (Czerniewicz and Brown 2009). On the other hand, an unstructured policy does not have any documentation nor support systems in place. Support given may be on the individual

basis and at the convenience of the technical support staff.

Some studies show that having an institutional policy expresses the commitment of the senior leadership to the change in the organization (Czerniewicz and Brown 2009; Nichols 2008). When there is no structured policy, staff will be constrained in the implementation of the innovation due to lack of support and vision (Czerniewicz and Brown 2009). Hence, although a policy may not be the force that moves the change, having a policy can ensure that the operations and activities related to the innovation are implemented (Czerniewicz and Brown 2009). Some examples of policies required are discussed next.

Information Policies

Information policies are specifically those “laws, rules, regulations, and guidelines, both formal and informal, that affect the way individuals and organizations collect, create, access, retrieve, disseminate, transform, curate, preserve, and destroy information” (Walster 2018, p. 143). In implementing e-learning, policies are required in all aspects of the e-learning environment such as privacy and security of personal information, creation and use of intellectual property, and guidelines on the use of copyrighted materials.

Walster (2018) suggests some information policies that should be documented:

1. *Policies regarding the privacy and security of personal information.* In most countries, the rights of the student until he is 18 years remain with the parents. For example, the US Department of Education, the Family Educational Rights and Privacy Act (FERPA) which protects the privacy of students’ educational information, may be applied differently at K–12 education and after secondary school. The institutional leader needs to be aware of this act and how it affects students.
2. *Policies regarding proprietary information which cannot or should not be shared.* Materials on the Learning management systems have different policies and distribution or access rights which might limit the access

to the resources or software. Variation in these policies needs to be made known to the users.

3. *Policies regarding information storage, backup, and destruction.* The systems, networks, servers, and storage facilities on where information can be stored and searched, as well as the back-up schedules if related, need to be made known and coordinated.

Examples of Information Policies by Function

Information policies may be categorized by function as they may affect administration, instruction, and learners. Walster (2018) provides some examples:

1. *Information policies which impact administration of e-learning environments.* Information policies which originate at the government level may influence the overall functioning of e-learning initiatives. Personal information privacy and security is affected by government’s central policies (e.g., FERPA), and this would translate to the learning management systems (LMS) privacy and security policies regarding personal information. However, information policy requirements for government and corporate sectors might be different. Corporate entities are under no such obligation to have information policies related to privacy.
2. *Information policies which influence the design and delivery of instruction.* Information policies on copyright guidelines, intellectual freedom, academic freedom, and library policies can impact the design and development of materials for e-learning. Issues which may arise are proprietary systems restrictions, user registrations, password protections, as well as privacy and security of personal information.
3. *Information policies which affect learners.* Learners have no choice in the selection of learning management systems, the way information policies are implemented, or how information policy is written for their organization. However, they should be made aware of their rights and responsibilities. This may mean that an organization needs to write information policies or procedures to inform

students of those policies which will affect their privacy and security, as well as on intellectual property, communication, access, and retrieval of data.

In conclusion, for improving the information policy environment, one needs to firstly, make an inventory of existing information policies in the organization. Next, evaluate the quality, consistency, and coherence of the information policies affecting e-learning. Finally, improve the information policies by making it current, while continuously revising, and coordinating policies when needed.

A Culture of Data for Decision-Making

Instructional leaders should cultivate a data culture within the organization. Data in school and institutions may consist of student records, curriculum materials data, program data, administrative data, and financial records. These data may not be compiled in an electronic or a usable form and may be stored in various places, not in a single repository. Hence, data needs to be organized to make it easily accessible. When a data culture exists, members of the institution know the need to collect relevant data to be transformed into knowledge for planning and organizing (Tolley and Shulruf 2009; Petersen 2012). The institutional leader needs to cultivate this culture.

Data management and analytic capacity can be developed among the staff so that the data collected can be analyzed to answer strategic questions. For example, in a New Zealand secondary school's transformation by the Academic Counselling and Target Setting (ACTS), the aim was to improve student success by increasing academic performance through a systematic data sets in the form of individual student's academic profiles (Tolley and Shulruf 2009). At the same time staff were encouraged to work on the academic performance of the school (Tolley and Shulruf 2009). The strategic plan of the institution had identified the educational knowledge available and what needed to be improved, and hence, a revision of the data management system was

done to include more relevant data analysis schemes which could enable longitudinal analysis, with feedback for the data management system and teaching staff (Tolley and Shulruf 2009). This intervention improved the culture of data among the staff, increased the use of data stored on the schools' database, and significantly improved the quality of data for the use academic counsellors as well as for student achievements (Tolley and Shulruf 2009).

Databases which can be used for accountability can be found in national education management information systems (EMIS). EMIS should be designed to manage and organize the information in a country's education system for education development and meaningful change. EMIS is usually centered within the Ministry of Education of a country. In countries with a suitable political-economic framework and demand for data-driven information, EMIS is successful (Tolley and Shulruf 2009). However, EMIS should not just be exclusively for educational data collection from all levels, but should instead be a means for institutions to collaborate with the central administration so that stakeholders can also transform data for decision-making in their context (Tolley and Shulruf 2009).

A data culture for research and decision-making should be cultivated so that there is easy access to databases (Petersen 2012). This is provided through many nontraditional learning platforms. Learning analytics has also potential for collecting data through new learning environments.

Developing Instructors' Capacities in Technology and Pedagogy

Institutional leaders need to prioritize the changes to be implemented according to the needs of the institution. In order to provide quality education, the improvement which should be carried out in classroom instruction and practice should be balanced with the vision of the institution as well as in other aspects (Hopkins 2001; Heaven and Bourne 2016). The teachers as implementer of the innovative practices will determine the success of

the changes. Hence, the teachers' understanding of the change, and their support in putting the change into practice, and for adapting the change into their particular classroom, needs to be developed (MacBeath 2009). This adaptation to the specific classroom is required as there is no one specific measure of accountability which can be used to measure the inner workings of the classrooms (MacBeath 2009).

Capacity Development

Developing the capacities of the instructor is an important aspect of instructional leadership. The level of involvement of the instructional leader can determine the success of an innovation or educational reforms (Heaven and Bourne 2016). Although teachers and instructors may be positive about the use to technology, their confidence, competence, and discomfort on the changes in instructional practice with a new technology may hinder the experience (Young 2016).

Instructional leaders should provide adequate professional development before and during the project (Young 2016). Continuous professional development has shown to be effective in developing teachers' confidence, competence, and usage of technology while improving their perception toward a new technology, even among those less skilled in technology (Young 2016). Hence, instructional coaching, mentoring, and training are required for building staff motivation and beliefs (Heaven and Bourne 2016; Kopcha 2010; Leithwood et al. 2004). Building staff capacity can encourage efforts in developing new pedagogies to cater to individual learner differences and encouraging creativity (Heaven and Bourne 2016; MacBeath 2009). The teachers' understanding and commitment to change is a major contributor to the success of the policy or reform and cannot be replaced by specific curriculum, elaborate text books, and other well-designed materials (MacBeath 2009). Hence, developing capacities is important for the instructional leader as he builds relationships among his staff (Heaven and Bourne 2016). He should also allow instructors sufficient time to prepare resources, practice strategies, share experiences,

and empower them to innovate (Heaven and Bourne 2016; Young 2016).

The role of the instructional leader to motivate and instill the belief in the reform among his staff is an approach toward quality (Gregg et al. 2018; Heaven and Bourne 2016). Implementing an educational innovation may require a change in pedagogies and approaches to teaching. Hence, sharing best practices and giving feedback for the implementation may assist the instructors in creating innovative and quality resources (Heaven and Bourne 2016).

Designing Learning Experiences

The educational institution which is accountable to its stakeholders should provide quality learning experiences for the learners. The instructional leader who is an expert in the educational innovation may also be able to guide, mentor, and coach the staff involved. However, if the instructional leader is unable to provide the support, he should consider investing in learning design and faculty development (Gregg et al. 2018).

Quality in teaching and learning refers to designing quality learning experiences and providing quality educational resources. For example for a technological innovation, the instructional leader would need to ensure there are sufficient curriculum resources in the digital form (Young 2016). These resources may be sourced from external providers or developed internally by the instructors or a team within the institution. Hence, a team of competent learning designers who have the ability to develop effective learning experiences for any delivery mode, whether online or blended or face-to-face, should be made available to ensure the success of the innovation (Gregg et al. 2018).

Most teachers teach the way that they were trained in (Gregg et al. 2018). Hence, if a new educational innovation is implemented, teachers should be trained to teach in the new pedagogy. For example, if an online course is going to be provided, it is only fair that the online course should be well-designed and that the instructors would be qualified and confident online course moderators (Gregg et al. 2018). Hence, instructors should be trained to be competent and qualified as

online instructors to ensure quality is maintained (Gregg et al. 2018).

The instructional leader may need to decide on the funding possibilities for developing capacities. Material development could be outsourced or developed by an in-house development team, and staff need to be trained to be skilled in learning design and for implementation of the educational innovation (Gregg et al. 2018). Before the course is offered, learning designers are required to design the learning environment, but when the course is implemented, instructors are needed to teach the course so that they can use, manage, and optimize the technologies in the courses (Gregg et al. 2018). Teachers may need to be trained as learning designers and online course instructors.

Instructional leadership plays a significant part on student learning. By developing the capacities of instructors, promoting a vision, and ensuring resources and processes are in place for instructors to teach well, it can have a positive impact on students' learning (Heaven and Bourne 2016; Leithwood and Riehl 2003).

Technology Infrastructure

Technology has been used to deliver instruction in both for online and for blended learning. The growing number of MOOCs and e-learning platforms attest to the feasibility of these platforms with the availability of data for accountability. However, are students provided with rich learning experiences using these technologies? To ensure the quality of instruction is maintained, instructional designers provide support for faculty and also manage new content delivery tools (Moore and Fodrey 2018). Administrators have now to align resources for the most effective and efficient models of delivery of instruction (Moore and Fodrey 2018).

Moore and Fodrey (2018) suggest a model for technology infrastructure for the educational institution. As instructional leaders seek to deliver quality experiences, they need to take into consideration the institution, student, instructors, and technology. Technology infrastructure

consists of the following components: the systems, objectives, personnel, and evaluation (Moore and Fodrey 2018). However, there urgently needs to be a systematic way to identify, evaluate, and implement tools that can support the mission and vision of the institution as the technology infrastructure service is a critical factor for the successful uptake of the technology (Alsabawy et al. 2013). Each of the components of technology infrastructure is discussed next.

Systems

In the systems component, firstly, the format or delivery method to create instructional content needs to be determined, followed by the platform or tool to deliver the content (Moore and Fodrey 2018).

There are a variety of delivery methods. When Moore and Fodrey (2018) discussed on the delivery of distance education, they focused on webinars, lecture captures, and e-learning modules. Webinars are synchronous recordings which enable direct interaction between instructor and students which can be recorded and archived as videos. The recordings can be done using a web platform, presented from the instructors' laptop, and normally accompanied with visuals and audio, and normally Powerpoint slides. Interactivity in webinars can be captured through polls, questions and feedback, and chat-based text. Lecture captures, on the other hand, are the digital representation of the lesson in the classroom as the recording is done during the lecture. These lecture captures can be viewed synchronously at a distance or accessed after the class session. However, lecture captures are not completely synchronous as there is normally a delay in transmission, and when synchronous activities like polls are conducted, there may be a lag time. Finally, e-learning modules are difficult as developing a self-paced module for instruction with sufficient interaction may take a lot of time. Interactive quizzes, and other user interactivity such as clicking and mouse-overs to reveal information and feedback can promote interaction. These modules do not require real-time interaction, but will need to be designed for self-paced and self-directed learning.

After the system for the creation of content has been determined, the delivery of the content created needs specific tools. Tools like Adobe Connect and Skype for Business have possibilities for video conferencing. Preset and Andrews (Preset and Andrews 2015) divided the range of tools into the “magic quadrant for web conferencing,” where the tools are divided based on the products and their features as *leaders*, *challengers*, *visionaries*, and *niche players*. Leaders are companies with tools which have a large market share relative with products which have a wide range of features, while niche players are companies which have good technology, but because of their service, they are limited to a niche area (Preset and Andrews 2015).

Objectives

The technology which is selected should serve its purpose in education. As Moore (2014) states technology should support learning and not just be added because it seems to be fun. Hence, the learning objectives must be clearly established, and the technology selected must be aligned with the objectives. This will also set the scope for evaluation as evaluation of the technology tool is based on the original purpose of the tool. Moore and Fodrey (2018) gave an example of an instructor who wanted his students to acquire specific concepts before they could be taught application and critical thinking. For this purpose, they suggested an e-learning module to cover fundamental concepts to be published and distributed to students using Adobe Connect. Quizzes in the module could provide the knowledge check, and the scores could be linked to an LMS, which would provide for the evaluation and accountability in the module.

Evaluation

The evaluation of the effectiveness of the tool for achieving the objectives is an important measure of success (Moore and Fodrey 2018). The evaluation should be done in two stages: initial evaluation of the tool before it will be used and continuous evaluation, which occurs after the implementation. Evaluation should be an essential component that needs to be done to determine

whether the technology meets the objectives of the course (Moore and Fodrey 2018). Evaluation may require mechanisms for feedback from the users and not just a technical evaluation.

Personnel

As technology infrastructure is an important requirement for an e-learning course, institutions need to ensure there is an instructional designer within the institution. The instructional designer needs to be able to work with instructors in integrating technology and aligning technology to learning objectives (Moore and Fodrey 2018). For instructors who have little experience in integrating technology in their teaching, this support will be beneficial. However, for instructors who are already adopting the technology, the instructional designer can help think of new ways and perhaps new tools to use innovatively in the classroom (Moore and Fodrey 2018). Another function of the instructional designer is that he will be the connection with the technical personnel within the IT Division. For example, an LMS administrator may not know which tools instructors and students require or work best with and may not know of the technical requirements such as bandwidth during deployment. These are decisions related to the pedagogy rather than the technology and may be addressed by the instructional designer. Hence, having an IT division team with an instructional designer involved could provide a more holistic and sustainable support structure (Moore and Fodrey 2018).

In conclusion, combining the knowledge of the pedagogical needs with the technological infrastructure, such as the Internet connectivity and Wi-Fi, may assist in addressing some of the problems of integrating technology in instruction (Young 2016). Gregg et al. (2018) suggest working strategically with educational technology vendors, either by developing specific solutions for your organization or adapting what is already in the market to the instructional needs. However, in order to determine which solutions work, they suggest that staff and faculty members be included as key stakeholders in making decisions. The staff and the instructional designers should decide on the educational technology solutions.

As there may already be many different applications being used in the institution, the first step may be to compile information on the existing applications and their licenses to determine whether there are overlaps in functions (Gregg et al. 2018). Assessing the instructors' needs to ensure that the solutions provided meet the requirements, providing updates on the procurement of the solution, and enabling the instructors to provide feedback on the use of the solution provide the instructors with a sense of responsibility for the solution and improve buy-in (Gregg et al. 2018). However, there is no one specific solution for everyone, and finding a means to obtain feedback on the technology to be used is important for the institution.

In conclusion, the technology infrastructure required needs to be considered with the instructors and their needs. The systems for creating and delivering the content, objectives, technology tool, mechanism for evaluation, and feedback and the personnel for creating the technology should be developed.

Community Involvement

Other stakeholders in the education process should be involved in ensuring that quality education is provided. Involvement of the staff, students, parents, community members, and other stakeholders can be used for a stakeholder-based approach to decision-making (Raish et al. 2018). The stakeholder-based approach which involves the community in solving issues takes on a horizontal accountability approach for formulating strategies, decision-making, and evaluation of education for improving quality of services in institutions (Hooze et al. 2012). This ensures transparency in the process of running the institution, where different perspectives and backgrounds are taken into account, and hence, can also gather buy-in from the community in the process of change (Raish et al. 2018). A shared responsibility is developed by students and their parents to members of the community and the community as a whole to ensure that effective and quality services are provided.

A shared, collaborative, and participative concept of leadership in this way can contribute to the organization's success (Leithwood et al. 2004). There are several aspects of community discussed in this section, parents and guardians as support for the education system, development of the online learning community for students and for teachers, as well as support from the community.

Parents and Guardians

In the school system, parents and guardians have a role in supporting their child's education. However, parents may not be aware of how they can support their children's education, and what role they should play. This is even more obvious when technology, for example, e-learning, is implemented in schools. Hence, the instructional leader should have a set of guidelines to inform parents of their roles, orientations, and the expectations, so that parents and guardians can be effective coaches (Raish et al. 2018).

Students' Online Learning Community

Successful e-learning happens when an online learning community is built. Students need to connect to their instructors and be active participants in the online interactions. However, students may be resistant to interacting online. One way to address this problem is having students take self-readiness assessment for individualized feedback on how prepared students are for online learning. This feedback can be used to identify students' strengths and weaknesses for the online learning environment (Raish et al. 2018). Next, during the e-learning process, the instructor needs to be able to connect with the students. This means ensuring personalized instruction and maintaining online interactions with students. The instructor will need to acquire new skills for learning and mentoring online. Hence, capacity building for the instructor to teach and mentor his students online is required. The culture of learning needs to change in the online environment to be more collaborative and constructivist as the instructor builds and supports an online community of learners.

Teachers' Online Learning Community

Capacity development of the online instructors can take place in the form of formal as well as informal professional development. Teachers and instructors themselves need to be supported in implementing new innovations. Gregg et al. (2018) suggests developing informal communities within the institution for this purpose. This community should be hosted on an online platform to support each other, share best practices, develop their skills, and also motivate one another in using the innovation. A community of practice for teachers and instructors practicing online learning is important as this fulfils the human social need. Just as a group of teachers would discuss their academic work in the staff room, providing a "workspace" online to conduct discussions can enable teachers to exercise their professionalism. Teachers and instructors may face problems while teaching online and having a technology support group which provides support by mentoring and coaching online motivate and empowerment them to use technology (Gregg et al. 2018). A community of practice with an instructional leader who is well versed in technology and pedagogy would be able to support the community and each individual. In addition, each member of the group also supports one another. This collaborative approach is more sustainable as teachers develop their expertise and mentor their peers. This in turn develops a culture of collaboration as there is a shared purpose and vision in using the technology and develops other leaders in the use of technology (Gregg et al. 2018).

Professional e-Learning Community

A larger community of practice among the professional e-learning community can be a source of information. Most professional e-learning communities believe in providing open educational resources for all and are helpful in sharing on topics such as institutional leadership, technology, instructional design strategies, online instruction, and policies impacting online education (Gregg et al. 2018). Many of these communities make up of blogs and podcasts to regularly post online. Gregg et al. (2018) suggests that the

instructional leader can identify professional networks which are appropriate for the institution and its community, and to participate in conferences, and subscribe to related professional organizations and blogs, as well as conducting related research.

In summary, community involvement includes parents and guardians supporting their children, learning communities which support students' and teachers' learning online, and being a part of a larger e-learning professional community.

Conclusion

In implementing a change or an innovation for institutional improvement, school and institutional leaders are accountable to their stakeholders to provide quality education. In setting the strategies for school and institutional improvement, the instructional leader needs to instill a shared vision in the institution to ensure that students, teachers, instructors, parents, and other stakeholders are convinced that a reform or a change will bring about quality teaching and learning. The instructional leader may need to develop a vision, relevant policies to ensure all the stakeholders are aware of their roles and function, and develop their capacities in both technology and pedagogies. The innovation should be customized to the institution, and the stakeholders should be involved in the planning.

Instructional design and development of staff capacities should not be neglected to ensure that instructors are capable of providing quality learning experiences. In addition, adequate technology infrastructure suitable to the pedagogy required should be provided. Finally, support can be garnered from the communities for institutional improvement as parents and other stakeholders get involved in the education process. In addition, learning environments for build communities of learners should be supported through online mentors, and these mentors and instructors should be provided a platform for developing their own professional learning communities. Other professional communities can establish support for

professional development as best practices and strategies are shared.

Hence, there may be other factors which are not discussed which may contribute to the success of an innovation in the intuition such as individual staff as innovators, having an institutional champion, and students as drivers of the innovation (Czerniewicz and Brown 2009). However, these are not discussed as the contribution to the reform is small. Any improvement effort or innovation should be a system-wide approach in order for successful integration with technology and should be embedded seamlessly within an organization in order to have institutional acceptance and for the institution to strive toward being the top quality in innovation.

The purpose of innovation in education is to provide quality education for the digital natives of the imagination age. In order to be accountable to these students, their parents and other stakeholders, school, and instructional leaders need to develop a vision, consider changes in policies, create a data culture, build staff capacities, develop learning communities, and provide for involvement of stakeholders in driving the innovation.

Summary

Schools and higher education institutions need to continuously improve in efforts to provide quality education as these institutions are accountable to their students, parents, members of the community, and other stakeholders in education. Students need to be equipped with the skills and knowledge for future jobs in the imagination age. However, school and institutional leaders may not be equipped with the skills to propel their institutions forward in a technology-rich world. Hence, schools and institutional leaders need to be supported in their role as instructional leaders to improve instructional practice and developing human capacity. Some suggestions and guidelines are provided to support leaders in inspiring the institution in achieving a shared vision, developing policies related to

the vision, building a culture of data for decision-making, developing instructors' capacities in technology and pedagogy, and providing the technology infrastructure and strategies for community involvement.

Introduction

The progression and evolution of information and communication technologies (ICT) has brought about large amounts of change structure-wise, including trade expansion, economic, and even concepts of globalization. Access through ICT has led to the enhancement of the availability of information. Looking back to the late 1990s, the Internet was just becoming available and mostly existed on university campuses or for the military. After a decade, Internet access and other technologies were seen more widely, and now many people have access to them.

In the last few years, it is undeniable that individuals, schools, colleges, and companies are spending more money and resources on technologies. However, there seems to be a lack of ongoing information about peoples' perceptions towards digital technologies, and how these might affect organizational structures or practices. This article explores this issue, with how individuals sustain their uses of digital technologies

over long-term periods; it will consider a case of Malaysian individuals' perceptions of uses of digital technologies, how change and adaptations are being sustained, compared to those in the United Kingdom (UK). It will explore drivers that contribute to how individuals adapt to ongoing changes that are happening in the technological world, and based on current research, offers a model for future development of sustained practice.

Background

Businesses are creating and capturing value, using ways of interacting and communicating, benefiting from where and how people are working, all arising from and due to the influence and changes of technology in the global world that ICT supports and enables (Cascio and Montaelegre 2016). Big data and machine learning, advanced robotics and drones, cloud and mobile computing, and technologies that are clean-energy are technologies which are currently at the emerging edge, transforming and driving the starting points of some businesses globally.

However, evidence from studies undertaken over the past 20 years or more (e.g., Gao et al. 2011; OECD 2015; Tatnall and Davey 2014) shows a repeated lack of long-term uses of digital technologies by teachers, trainers, and employees to support what would be regarded as effective enactment, for their teaching, training, or work-based practices. While studies have identified drivers and barriers (e.g., Conole 2016; Porter and Graham 2016), studies exploring reasons for long-term sustained uses have not emerged as frequently (e.g., Mumtaz 2000). Developing effective practitioner enactment (Heitink et al. 2016; Khan et al. 2016) requires detailed knowledge about relationships of factors and features that enable teachers, trainers, and employees to understand how and why they can use digital technologies in their respective work areas. Features and factors enabling use not only concern professional attitudes and understanding of technological affordances and facilities but also

attitudes and understanding towards technologies and, importantly, innovation. If appropriate learning, teaching, training and work-based uses are to develop over periods of time, rather than being restricted to the short-term, to accommodate rapid technological changes, then enactment should be concerned not just with pilot and project-based uses, but with long-term interactions where adaptation and change facility are inherent to professional practice.

Factors that can affect an individual's attitude towards any kind of new technology might be their age, gender, or even their peers' attitudes and perceptions. There are challenges when introducing new technologies, such as achieving user acceptance, but at the same time, organizations are also trying to retain levels of acceptance when it comes to performance and productivity (Ahmad 2014). Reasons why companies or organizations are introducing new technologies can be to increase quality and productivity, to reduce costs and dependence on skilled labor, to be up-to-date, to retain their position when competitors also introduce new technologies, and to change relations and interactions among various groups within organizations (Dawson 2007). In many businesses and organizations (including those that are educationally focused), there is an increase of participation among employees who are remote or faraway. Technologies can assist and expand the number of employees who are collaborating or working together with technology tools such as the Internet, shared databases, and internal intranets. Regardless of location (accepting Internet accessibility), technology enables sharing challenges that are faced by remote employees to be overcome (Schraeder et al. 2006).

The most unavoidable factor in the business world is change. It is important for an organization's toolset to be upgraded on a regular basis, and furthermore, their employees and staff need to accept changes applied. Changing employee and staff perceptions and behaviors cannot be done and forced overnight; it is a long-term objective, a critical factor being the provision to the employees of the full context of the changes, as this will allow them to understand the need for such changes (Croft and Cochrane 2005). When it

comes to organizations, it is the role of managers to provide justifications, reasons, and rationales as to why it is necessary to make these changes in order to create a degree of readiness, as this will increase the likelihood for the employees to accept and participate in the changes applied (Ford et al. 2008). Furthermore, managers play a very important vital role in coordinating, controlling, and leading employees within their businesses, to ensure that any technologies that are integrated into use are technologically fit for the purposes of the organization (Kao et al. 1996).

A factor that can influence a manager's performance is, firstly, training. Training and sufficient guidance should be provided to employees on how to use new technologies if the technologies will be an essential tool for the business, and such professional technological training needs to be taken seriously, with an appropriate transition flow (Alan 2010). This should be considered and viewed as a vital investment (Reese and Porter 2008). A further factor for managers to consider is modern technology's mobility. What most managers look for are tools that enable them to do their tasks at any given time and even for them to bring their work home or their abilities to complete it in any location beyond the office. Mobility of the technology helps in increasing profitability and also productivity (Pfano and Beharry 2016). Usefulness, when it comes to office technology, is a factor; and technologies that are indeed useful may well be used every day (Billhelf 2006).

In order to implement a technology change successfully, areas that need to be addressed effectively include any internal conflict challenges or resistance by employees, adequate consideration and planning of an employee's training, multigenerational workforce concerns, and communication. All of these can be addressed, involving an implementation plan that is adequately conceived, a training plan that is feasible and potentially effective and, lastly, when it comes to communication between management and employees, there must be open communication (Delaney and D'Agostino 2015).

In this digital era, the use of computers has become easier, offering benefits that arise from

new functionality. It is undeniable that all areas of production in many organizations have been transformed by the computer (McConnell 1996). Many organizations are devoting their resources so that their employees are gaining substantial training, as training is seen as a “must” to keep oneself updated. The University of Virginia, for example, is constantly providing computer training for their staff (some two to three thousand in number) with workshops that have involved total participant numbers up to 2000 for the last 4 years. The training hours total about 3.86 per employee per year (Friedberg 2003). Subsequently, organizations are showing benefits as a result; one organization that spent a great deal on purchasing a large number of computers showed a greater reciprocity when it comes to skilled labor (Eric and Loren 1997; Lehr and Lichtenberg 1998). Since the 1990s, there has been an increasing awareness regarding on-the-job training as the most appropriate method of educating and teaching employees necessary skills (Jacobs and Jones 1995). Furthermore, support from peers and supervisory personnel are variables that have contributed to the effectiveness of training programs (Bates et al. 2000).

On-demand businesses are now combining technology with information technology, so that these companies can be profitable, responsible, and rapid. Today, enterprise considers flexibility as a key factor. Flexibility in this sense is concerned with adaptability when responding to any kinds of new demands in the current market and taking whatever opportunity may come along (Tohidi 2011). User satisfaction with using technology is undeniably important. What contributes towards how well any resources are being utilized in an individual’s work life depends on their aptitude, ability, attitude, and even beliefs about information technology (Venkatesh 1999).

Cases in Malaysia and the UK

An example study which illustrates key points about sustainability of digital technology practices, conducted in the UK and Malaysia (Passey

and Lee 2018), gathered qualitative data about individual approaches to sustaining uses of digital technologies for learning, teaching, and training. Interviewed participants had used technologies in their careers for learning, teaching, and training purposes for many years. The study gathered evidence about:

1. How long the participants had been using technology devices to support learning, training, or employment.
2. Over that time, what hardware changes they had encountered, and which devices they had used at different times over that period.
3. The software changes they had encountered over that time, which software they had used, and when they started to use these.
4. What their experiences were in terms of performance when they started to use new hardware and software – for example, whether it went down, stayed the same, or went up and how long these sorts of shifts in performance lasted.
5. The benefits they experienced from uses, whether these were what they would regard as the most important benefits, and whether these shifted at all over time.
6. How they managed to maintain uses of technologies when software or hardware changed, and what they did so that they could use the new or updated software or hardware.
7. Whether there were other people around them, in their situations or context, which made a difference in this respect, and if so, whether they would say those differences were positive or negative.
8. Whether there were particular contextual factors that had been important in helping them to adapt to new technologies at certain times. For example, whether they would rate any of the following as being important to sustaining their enactment in the school, college, university, or work:
 - (a) A shared vision of technological uses
 - (b) Empowerment from leaders
 - (c) Implementation planning
 - (d) Consistent and adequate funding, either personally or from the institution

- (e) Equitable access, compared to others
 - (f) Ongoing professional development
 - (g) Technical support
 - (h) A framework of how to use the technologies in the institutional curriculum or work plan
 - (i) The ability to choose when to use the technologies
 - (j) Assessment and evaluation of their practices using technologies
 - (k) Engaged communities of users
 - (l) A supportive external context at home or outside the institution
9. Whether any of these factors, or others, hindered their ability to adapt to technology changes over time.
 10. How they considered the value of uses of technology overall – for example, as a requirement, or something that is useful, as a tool, an add-on, something about which they need to be kept informed for their learning, training, or work.
 11. Whether they thought it was important to maintain contact with and integrate technology with their learning, training, or work, and if so, why they thought that was so.
 12. What they thought the main personal factors or characteristics were that enabled them to adapt to technology changes over time.

A total of 16 respondents from Malaysia and 14 in the UK participated in the studies. Most were men (20 compared to 10 women), as shown in Table 1.

From Table 2, it can be seen that most of the respondents in the study coming from Malaysia were between the ages of 21 and 40 years (a younger adult group), whereas the respondents in the UK were mostly aged between 41 and 60 years (a middle-range age group).

Table 3 shows that most of the interviewees had been using technologies for 10–20 years in Malaysia, while in the UK most had been using technology for longer time periods, for 21 years or more. Compared to the UK, participants in Malaysia had used technology for shorter periods of time.

Sustaining Digital Technology Use in Professional Communities, Table 1 Genders of the participants interviewed

Gender	UK	Malaysia	
Women	6	4	10
Men	8	12	20
Total	14	16	30

Sustaining Digital Technology Use in Professional Communities, Table 2 Age ranges of interviewees

Age band	Malaysia	UK	
Between 21 and 40 years of age	14	2	16
Between 41 and 60 years of age	2	11	13
61 years of age and above	0	1	1
Total	16	14	30

Sustaining Digital Technology Use in Professional Communities, Table 3 How long technologies had been used by the interviewees

How long technologies have been used	Malaysia	UK	
For up to 10 years	9	1	10
Between 11 and 20 years	7	3	10
Between 21 and 30 years	0	6	6
31 years and over	0	4	4
Total	16	14	30

Experiences of Long-Term Sustained Users of Digital Technologies

When asked about their experiences with hardware changes over the times they had been using the technologies, and what kinds of devices they had used over that period, most Malaysian participants stated they had used laptops (8 respondents), tablets (3 respondents), CD-ROM (Compact Disk Read Only Memory)/floppy disks (3 respondents), mobile telephones (7 respondents), monitors (5 respondents), thumb drives/external hard-disk drives (3 respondents), and mobile technologies (2 respondents). Some also identified the Internet, Microsoft (MS) Windows, televisions, sensor devices, gaming devices, digital audio recorders, the iCloud all system, telephone cables, printers,

keyboards, mice, and Wi-Fi that they had used before as time went on. Compared to the UK study (Passey and Lee 2018), respondents in the UK related hardware changes they encountered based on periods of their life such as their childhood, their first job, etc.

When asked about software changes, Malaysian respondents clearly recognized changes when they moved from one software to another such as Microsoft (MS) in general (5 respondents), MS Word (3 respondents), MS PowerPoint (3 respondents) and MS Excel (2 respondents), and 9 respondents recognized the changes more when it came to using Adobe software like Illustrator and Photoshop. Other software changes identified were related to more specific packages, the iPhone Operating System (iOS), virtual private networks (VPNs), Oracle, computer languages such as Turbo Pascal, visual basic (VB), Java, standardized query language (SQL), SAS Visual Analytics, Webex, Shem's Risk Management System (SRMS), fourth generation language (4th GL), computer-aided design (CAD), X-Mind, and Figma Sublime software. Respondents from the UK did not relate software changes to periods of times when they used them, instead identifying the changes of software in a more general way, concerned with features and functionality of the software. This difference between the respondent groups might be related to the different lengths of times that the respondents in the two countries had used technologies.

When interviewees in Malaysia were asked about their experiences in terms of performance of new hardware or software, most respondents agreed that performance had increased significantly (6 respondents) and also they noted productivity increases too (4 respondents). Some agreed that technologies had become more user-friendly (3 respondents), loading time was faster (2 respondents), their learning improved the more they used it (1 respondent), it was more consistent (1 respondent), and hardware had got better (1 respondent). A few participants thought technology performance had stayed the same, or it took some time to adapt to it, or some trends did not fit their preferences. In the UK, respondents referred to more specific categories of

performance of the new hardware and software in terms of increased efficiency, enhanced access, improved performance, and enhanced ease of use.

Interviewees were also asked about the benefits they had experienced from the use of technologies. Most in Malaysia said it definitely improved their productivity (7 respondents), it also saved time (3 respondents), and helped them to communicate and work more easily (3 respondents). Other benefits mentioned were increased convenience, efficiency, gaining more security, and greater experience and basic knowledge of using the software over time. This pattern was similar to that recognized by the UK respondents.

Regarding the question of how they managed to maintain their uses and address challenges of changing technologies and what they did in order to use the updated software or hardware, most Malaysian respondents said that they sought help online either through a tutorial/guide/wikiHow/forum (8 respondents), YouTube (3 respondents), or Google (2 respondents). Five respondents said they taught themselves how to use the software, while two respondents went on many courses or read books and just updated on the basis that was needed. Three respondents asked somebody else or just tried it out themselves, and one respondent said they tested before updating or just went on a training course when the programs were much more sophisticated. The UK participants related similar responses, but, perhaps related to their age profile or not, the way they resolved their challenges was by talking to people who were "IT savvy" which they said "helped them a lot." They were also influenced by their children's uses of technology, including using technologies that enabled them to communicate with their children. Additionally, they said that support units in their places of work or employment, such as IT support, helped them too.

Table 4 shows interviewee responses regarding questions about particular contextual factors that they regarded as being important in helping them to adapt to new technology. All of the contextual factor specified were important to many respondents, but those highlighted especially were implementation planning (29 responses in total) and engaging communities

Sustaining Digital Technology Use in Professional Communities, Table 4 Contextual factors influential in maintaining sustained uses of technologies over time

Contextual factor	UK Yes	UK No	Malaysia Yes	Malaysia No
1. A shared vision of technological uses	11	3	14	2
2. Empowerment from leaders	12	2	14	2
3. Implementation planning	14	0	15	1
4. Consistent and adequate funding, either personally or from your institution	12	2	14	2
5. Equitable access compared to others	8	6	14	1
6. Ongoing professional development	9	5	14	2
7. Technical support	6	8	14	2
8. A framework of how to use the technologies in your institution's curriculum or work plan	11	3	14	2
9. The ability for you to choose when to use the technologies	7	6	12	4
10. Assessment and evaluation of your practices using technologies	10	4	14	2
11. Engaged communities of users	11	2	15	1
12. Supportive external at home or outside your institution	10	4	13	3

of users (26 responses). The least commonly highlighted was the ability for them to choose when to use the technologies (19 responses). It is clear that respondents rely upon a variety of supportive factors, rather than any specific factor or group of these.

From the details within Table 4, it is clear that the shared vision of technological uses, empowerment from leaders, implementation of planning, consistent and adequate funding from the institution, a framework of how to use the technologies in their institution's curriculum or work plan, and engaging communities of users showed similar high response rates for both countries. The majority of respondents agreed that these factors were key in influencing them on sustaining the use of technologies over time. The responses of Malaysian and UK participants were different when it came to accessibility of the technologies, technical support, and professional development. The younger age range adults from Malaysia said more commonly that the factors of accessing technologies when they chose to, and to seek support easily were important, whereas a lower proportion of the middle aged group from the UK indicated the importance of factors concerned with when to use the technologies and to access technical support.

When asked if the factors mentioned had hindered their ability to adapt to technology

changes over time, some indicated that this was the case. While some indicated hindering reasons like limited funding, only one respondent indicated that implementation planning was a hindering factor.

Interviewees were asked how they considered the use of technology overall. Some respondents in Malaysia said that it was essential and necessary to their work (4 respondents). Two respondents stated each of following: as a requirement to adapt to new technology, or something that is useful; or as a tool, an add-on, or something that you need to keep involved in with how you learn, train or work. Other participants stated that technologies are needed to maintain today's standards, to evolve, to keep up with changes of technology, as a vital tool, making sure technology can be used, but to make sure that it is fully utilized, to engage students, or help customers to meet their requirements, including uses for communication. In the UK, responses generally indicated the essential value of technologies, to support and enhance productivity and communication.

Participants were asked if it was important to maintain contact with and integrate technology with learning, training, or work. Many participants in Malaysia agreed that it was important (12 respondents). The reasons given for this were to use technology to appropriately encounter

obstacles that it is easier to stay connected, to solve problems immediately, to stay up-to-date in the IT industry, that the world is growing and so technology is surrounding us, and to make sure that we are updated with technological enhancement. A similar pattern of responses was gained from the UK participants, who indicated that changes in technologies were providing positive enhancements for addressing issues and challenges but that these might need to be explored by the individual within their specific contexts.

When participants in Malaysia were asked what they thought were the main personal factors or characteristics that had enabled them to adapt to technology changes over time, many of them said self-exploration (3 respondents), being humble and willing to learn things (3 respondents), personal interest (2 respondents), and curiosity of new technology (2 respondents). Others indicated the need for a positive attitude towards technology, enjoying learning, having an inquisitive nature, having a passion with gadgets, confidence, being positively responsive to change, and being sensitive to what is out there. The UK participants responded similarly, but highlighted key characteristics such as inquisitiveness and having a positive attitude towards technology.

It was clear from both sets of respondents that personal factors or characteristics were vitally important in enabling individuals to maintain their interest in and abilities to accommodate change with technologies over time. The role of personal characteristics and attitudes is shown across these samples of long-term users to be significant; the role of technical training is stated far less. Rather, it is access to individuals or resources that can support technical training that is reported as being more important than the technical training per se.

Factors that Contribute to Sustained Uses

Based on previous research literature and on the analysis from this case, it is shown that participants who have been involved in long-

term use of technologies to support their learning, teaching, training, and work-based practices are finding ways to accommodate to change in technologies. With regard to using previous hardware and devices, individuals may recognize that they had noticed changes with the introduction of certain technologies – mobile technologies, tablets, laptops, floppy disks, CD-ROMs, and thumb drives. In terms of software changes, it appears to depend on the specific forms of software that individuals need to use and choose to use, but individuals may recognize changes in software that have been available over quite long periods of time, such as Microsoft and Adobe products, as well as more specific software applications that are used for specific purposes. Reasons for noticing these changes may well be related to advancements in the technologies that have brought significant benefits, as those who sustain uses highlight increases such as those in performance and communication, and greater consistency in hardware, leading to improvements in productivity due to increased speed and loading time, with less waiting time involved. Regular software updates are noted to introduce friendlier user interfaces leading to greater overall usability. Importantly, “practice makes perfect” can be an overall concern of long-term users – by consistently exploring, accommodating beneficial affordances, and using software; over time, this leads to its becoming easier to use. The introduction of smartphones, tablets, and laptops can be noted to enable access and work to be done anywhere and anytime, leading in many cases to increased convenience, efficiency, and productivity. However, the dependence on technologies and the need to respond anytime and anywhere can be seen by some as an issue that needs to be considered and managed carefully, to ensure that personal time is not invaded inappropriately.

To enhance the learning of new facilities in technologies, materials and sources on the Internet are increasingly mentioned as a preferred choice, with many tutorials online which can help. Some long-term users indicate that they prefer to do things on a trial and error basis, while others prefer to refer to more documentation. With the need to use and apply new hardware

or software to an individual's context, a single approach may be adopted by an individual, but a variety of approaches are likely to be taken across a population.

Technological advancements have not only provided an increase in productivity, performance, efficiency, or convenience in work and jobs but they have been recognized by long-term users as creating a platform for communication across individuals. Some significant responses highlight benefits, such as the positivity of technology advancements which helped a single child deal with loneliness, as well as how older generations are accepting technological changes that can be an inspiration to others. In some cultural contexts, such as that in Malaysia, if younger people see their parents or older generations using smartphones and tablets with ease, it is felt that this may well trigger a common topic of conversation, where people would talk about how "even the older generations are attracted to the use of these technologies."

In terms of particular contextual factors being important in helping individuals adapt to new technologies, evidence has shown that through adequate engagement and empowerment, planning, adequate resources, technical support, and the ability to choose which technology to use, such factors are influential in mainlining the sustainability of uses of technologies.

The evidence that personal characteristics, which are consistently related by individuals who develop practices and uses of technologies over long-time periods, is of particular note. Characteristics such as self-exploration, a willingness to learn new things, personal interest, having a positive attitude towards technology, having an inquisitive nature, and being sensitive to what is out there and what is possible, are all key factors that individuals rely upon to develop uses to suit their needs. This focus on the personal characteristics has been somewhat underplayed by the support community, yet is clearly an important area for future concern.

The integration of technologies with learning, training, and work has been deemed to be important, as it allows individuals to solve problems, to act as a communication tool and

to provide individuals with the means to stay updated. While technologies have increased productivity, efficiency, speed, and performance as well as provided people with a platform of convenience, it is clear that this has arisen as a consequence of their personal interest, drive, and inquisitive concerns.

Approaching the Development of Sustained Uses of Digital Technologies

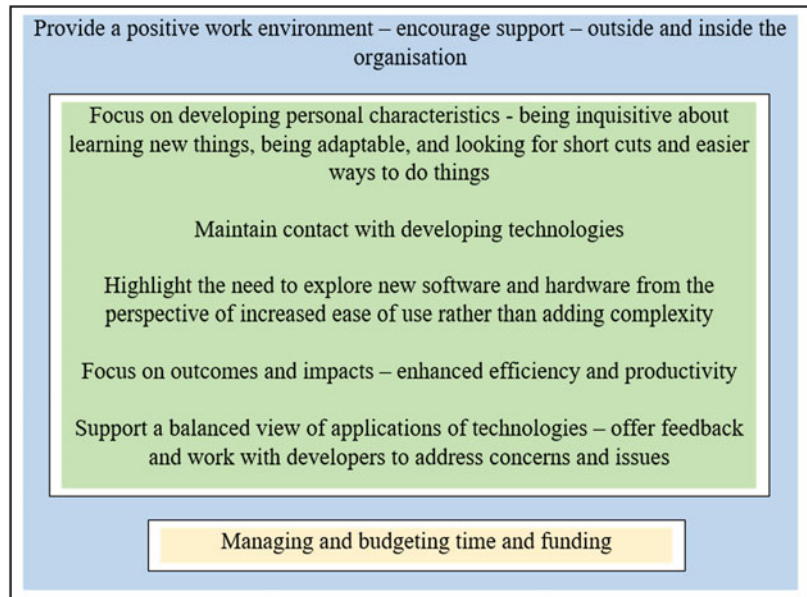

In conclusion, research studies have provided an overview to show that individuals who continue to use technologies for long periods of time are accommodating and accepting of technological advancements and changes. More importantly, the drive behind the acceptance of change is due to a willingness to learn, a sense of curiosity, and a positive attitude towards technology. Thus, sustainability of uses of technologies in communities seems to suggest a positive future in this respect where positive attitudes are positively supported. It is not so much a matter of whether it is a choice for people to accept but is more about adaptability and willingness to accept these technology changes and to explore how they can be of value. In countries studied, individuals with long-term use have learnt to understand the potential and importance of technology, how it can and has benefited their daily lives (whether for personal or work purposes), and how, due to emerging technologies, it has enhanced their lives.

A proposed model for future development of sustained effective and innovative uses of technologies is offered in Fig. 1 (from Passey and Lee 2018). Features of this model relate to factors for successful professional development identified earlier by Joyce and Showers (2002): persistence; acknowledgement of the transfer problem; teaching new behaviors; understanding the importance of the underlying theory; proactive and productive use of peers; and flexibility. Evidence from current studies confirms a continued need to focus on these affective, as well as technological, content, and pedagogic factors.

Research findings suggest that institutions that have focused on providing technical support alone

Sustaining Digital Technology Use in Professional Communities,

Fig. 1 Proposed model for future development of sustained effective uses of technologies. (Source: Passey and Lee 2018)

should rethink their positions. Rather than a single focus on technical support and affordances, evidence indicates that institutions should focus on developing personal characteristics concerned with enquiry and inquisitiveness, highlighting outcome and impact support. This suggests moving away from technical support that focuses on affordances alone, to a focus on outcome and impact support. While there is a clear continued need for essential technical maintenance and implementation to interface with institutional foundations, ensuring infrastructure and accessibility, outcome and impact support for users from a developing personal characteristics perspective is vitally important. It is clear that some support in some institutions is provided in this way, with a distinction being made between infrastructure and network support, and user interface support. However, evidence argues for a focus of user interface support to be on developing creative and innovative personal characteristics that can be applied to technologies. There is clearly a need for institutions and individuals to consider the growing importance of developing digital agency at a personal level (Passey et al. 2018).

Introduction

Over the past two decades, the use of mobile technology devices in the higher education setting has expanded rapidly. Beginning with laptop computers and personal digital assistants, which became widespread in the early years of the twenty-first century, and continuing with smartphones and eventually tablets, these mobile technologies have had a profound effect on the connectivity, research productivity, and study habits of learners, as well as the classroom dynamics, research productivity, and expectations experienced by faculty. The increased use of a variety of information and communication technologies (ICT) among students is documented in Barry, Murphy, and Drew (2015), and this increase in technology use has produced an enormous body of academic literature examining such topics as adoption decisions, implementation strategies, the impact on learning and academic achievement, and student and faculty perceptions; reviews of the literature examining multiple ICT technologies within higher education have been conducted by Baran (2014) and Moreira, Ferreira, Pereira Santos, and Durão (2017), among others. Among the many competing ICT technologies that have become omnipresent throughout higher

education, this chapter examines the use of tablet technology, a relatively new technology which has been growing in popularity.

Although the first consumer-marketed tablet computers were introduced by Microsoft in 2000, the technology did not achieve mass-market appeal until the release of the Apple iPad in 2010. Since that time, tablet technology has, in particular, become a substitute for laptop computers, a technology that had become widespread in higher education in the preceding decade. A study in 2013 by Cassidy et al. (2014) conducted at an American University found that 33.6% of students were by that point using tablets and 87.5% of students were interested in using one for their studies.

This interest among students was a driving force for numerous universities mandating the use of tablets in specific classes or programs. As a result, many higher education institutions made rapid changes to their systems in an attempt to adapt and embrace the introduction of tablet technology. However, bureaucratic layers within these organizations can prove to be cumbersome and slow down the establishment of new cultures, pedagogy, and structures. Ideally, organizations should proactively plan change interventions to improve organization effectiveness and the well-being of individuals within the organizations. In practical terms, this involves subject matter experts identifying key priorities and offering suggestions that then guide an organization through the change process (Nielsen 2011). Normally, these plans would involve input from key stakeholders, and the formation of an action plan developed after several in-depth levels of analysis, which include environmental factors, organizational culture and systems, leaders, individuals, and respect for interwoven processes (Mintzberg 2011; Wardley et al. 2014). During this planning stage, students and practitioners would be considered significant players in the implementation of new initiatives, and their insights would be incorporated. This process can take time and does not always keep up with demands for the latest forms of technology. Within institutions, policies, and systems are established to reinforce the organization's culture and increase efficiencies. When trying to move

quickly to implement a change process that will impact every aspect of the organization, a whole new set of organizational goals, policies, and processes is necessary. Unfortunately, when dealing with established organizational cultures, moving too fast can create barriers to the change process, including organizational and individual resistance and system failures. Many of the early adopters of tablet technology faced these limitations. Some of these "growing pains" are identified below, but these types of learning tools, when properly implemented, can offer opportunities to advance university graduates' skills, preparing them for today's technology-driven workplaces. The experiences of students and faculty in tablet programs have produced a large and growing literature that forms the basis for this chapter.

Several themes have emerged in the study of tablet technology including the development of implementation strategies that can be replicated; the impact of the technology on student academic performance; student perceptions of, and satisfaction with, the device; and faculty perceptions of the technology. While the majority of studies have used the Apple iPad (e.g., Lee (2015) review, 18 studies specifically examining the use of the iPad in teaching and learning), some studies have examined competing tablet technology such as the Microsoft Surface Pro (Percival and Claydon 2015). In many cases, the findings examined in this chapter are generalizable to a broad range of tablet technologies, and therefore, in the following sections, specific tablet models are mentioned only when results are applicable to that specific model. The purpose of this chapter is to inform stakeholders about the driving forces behind the implementation and acceptance of tablet technology in higher education and guide them, so they can overcome resistance to adoption.

Faculty Experiences with Tablet Technology

Individuals resist change for many reasons including a lack of aptitudes or knowledge, a perception that there is no personal gain, fear of looking foolish, and a lack of trust in those in charge

of the change efforts. These barriers to change, experienced at the individual level, impact group dynamics and the organization overall. Many of these points of resistance have occurred during the introduction of tablet technology in university classrooms.

Many faculty who have adopted the technology have expressed positive perceptions of its value as an education tool (e.g., see Dennen and Hao 2014; Drouin et al. 2014). Nevertheless, resistance to a tablet program has been found among some faculty members who felt that having to redesign their course curriculum to integrate the technology infringed on academic freedom (Mang et al. 2017). Additional faculty concerns have been uncovered by Souleles, Savva, Watters, and Annesley (2017) who find that faculty are weary of the potential of the technology to distract students in class, although Mang and Wardley (2012) show that tablets are potentially less distracting than other common classroom technologies. Souleles et al. (2017) have also reported that faculty were concerned with the time investment necessary to become familiar with the device and the time investment required to select appropriate software applications and devise methods for their integration, and some were unsure about the learning benefits of using tablets.

Among faculty who have adopted the technology for use in their classes or programs, common uses of the tablets include direct connectivity with students, annotating student reports, conducting student assessments, and presenting or demonstrating the course content (DiVall and Zgarlick 2014). However, as the current generation of tablets requires a wired connection to a projector, the adoption of the tablet for presentation purposes continues to limit faculty to a stationary position within the classroom, and some faculty have reported preferring wireless projection technology so that they can move around the classroom with their tablets rather than being tethered to a projector/podium (Percival and Claydon 2015).

Nevertheless, beyond the impact on teaching, the implementation of a tablet program has created a new research trajectory for participating faculty; many of those who have adopted the

technology have begun to undertake scholarly work including conference presentations and the production of peer-reviewed publications regarding the technology and its implementation (Drouin et al. 2014). The many trials, reflections, and recommendations of these scholars have contributed immensely to the compilation of this chapter.

Student Perceptions of Tablets in Higher Education

A major theme of the literature exploring tablet use in higher education has been an examination of student perceptions of, and satisfaction with, the device. Robinson and Burk (2013), Rossing, Miller, Cecil, and Stamper (2012), Mang and Wardley (2013), and Wardley and Mang (2015) have all found that students perceive the technology very positively when used in class; as well, Hahn and Bussell (2012) have reported positive perceptions among first-year students regarding both in-class use and use of tablets outside of class. However, some students have been unsure about whether tablets provide any educational benefit beyond what is available with competing technologies such as laptop computers (Kinash et al. 2012).

Common uses for tablets among students include note taking (van Oostveen et al. 2011), reading electronic textbooks (Weisberg 2011) and magazines (Wang et al. 2016), exploring material related to the course content, and completing quizzes and assignments (Young 2014). In particular, Percival and Claydon (2015) have found that students believe the ease of taking notes and the ability to use electronic textbooks rather than carrying around multiple physical books are key advantages of tablets. However, Weisberg (2011) has found that the proportion of students who prefer to use a tablet as a secondary source of course content, such as reading an electronic textbook, and prefer to also have a traditional textbook is higher than the proportion of students who prefer the tablet as their primary source of course content and textbook; there is thus heterogeneity in views among students regarding the device, and not all perceptions have been positive.

Despite the noted advantages, students have listed several disadvantages of using tablets in class including the small screen size and potential for software incompatibility (Percival and Claydon 2015), a dislike of typing on the tablet screen compared to a computer keyboard (Fischman and Keller 2011; Wieder 2011; Christiansen 2015), and a constant reliance on wireless connectivity to make full use of the device's features (Hashim 2014). Students have also expressed concern with the potential for distraction in class (Young 2014; Percival and Claydon 2015), a serious issue given that other mobile technologies such as smartphones and laptops have been shown to cause distraction and lead to off-task behaviors, such as viewing non-course-related content and social networking, which negatively impacts academic performance (see, e.g., Wood et al. 2012; Junco 2012; Junco and Cotten 2012). Nevertheless, Mang and Wardley (2012) have found that the use of a specific tablet, the Apple iPad, which lacked the multitasking capabilities of laptops and some other tablet devices, significantly reduced off-task behaviors including social media and instant messaging usage compared to the use of laptop computers in class. But a better strategy than relying on the device to restrict unwanted behavior is to demonstrate to students how its correct use will benefit them as more recent changes in that technology to improve multitasking ability may have diminished its usefulness in regard to distraction mitigation. More research on the degree of distraction caused by tablets versus the distractions caused by other devices is needed at this time.

With the introduction of tablets, students have reported that they found the class more interesting (Young 2014) and that the technology helped to create a sense of community and provided students with greater confidence to share ideas with their peers (Wakefield and Smith 2012) and improved students' general satisfaction with their instructor (Wakefield et al. 2018). Overall, students have, in many cases, responded very positively to the adoption of tablets in their classes. Although the adoption process is not without its challenges, students' enthusiasm for

the device (see, e.g., Cassidy et al. 2014) provides a solid foundation on which to build a successful tablet program. Mang and Wardley's (2012) recommendation to manage student expectations through careful explanation of the purpose and benefits of the technology is one strategy to encourage positive student reception. In addition, Minty-Walker, Wilson, Ramjan, and Glew (2017) recommend the creation of a training program for students on how to use the device, noting that effective advanced training is necessary in order for the device to be used to its full potential as many students may come into a tablet program with only a basic knowledge of the device and may not have time to explore its full functionality on their own. In light of student difficulties in adapting to the device noted by Fischmann and Keller (2011), a well-crafted training program that orients students and prepares them to use the device in class should be expected to improve students' perceptions of and enjoyment from using the tablet.

Academic Impact of Tablet Technology

Student perceptions of using tablets in class have generally been positive; however, of chief concern to faculty and institutions is whether or not the technology has positive academic benefits for students. Not all studies have found significant academic benefits to tablet use; van Oostveen, Muirhead, and Goodman (2011) have compared tablet users to laptop users and found that students using tablets did not demonstrate meaningful learning beyond that achieved by laptop users, indicating that, from a learning perspective, the technologies may be close substitutes. As well, Scibora, Mead, and Larson (2018) have found that tablet users had lower engagement and lower attainment of course objectives than nonusers, a result which contrasts with Wakefield et al.'s (2018) and Wilkinson and Barter's (2016) findings; however, Scibora et al. (2018) found that both tablet users and nonusers perform similarly on graded assessments. At the time of writing, no study has yet demonstrated any meaningful negative

academic impact from tablet use, whether compared to other technologies or compared to the absence of technology; much of the existing scholarship has instead demonstrated a variety of avenues by which tablets improve student academic performance.

Tablet use has been shown to motivate students to complete their homework before tutorials and has led to improved student academic performance in the sessions (Wakefield et al. 2018). Adopting tablets has been shown to lead university students to read more often than they otherwise would (Wang, Chiu, Ho, and Lo 2016), an activity often known to improve literacy and academic performance. Furthermore, the ease of access to course material has been shown to increase the amount of time students spend studying as a result of adopting tablets (Hashim 2014; Lazarus et al. 2017). In addition to the academic benefits reaped from extra time spent studying, introducing tablets has also positively affected attendance in classes where the technology is used (Wilkinson and Barter 2016), though this result is perhaps not surprising given the body of research demonstrating students' positive perceptions of the technology. There is thus a multifaceted impact covering numerous academic behaviors, providing significant evidence that the adoption of tablets in higher education is leading students toward greater engagement with their course material.

The improved student engagement resulting from tablet adoption has led to evidence of improvements in graded assessments (e.g., see Wilkinson and Barter 2016; Morris et al. 2016; Raney 2016), as well as skills development. Using tablets in university classes can specifically improve students' oral, written, and graphical communications skills as well as critical thinking abilities (Bagdasarov et al. 2017). Furthermore, improved problem-solving skills among students (Wakefield and Smith 2012), increased student collaboration (Weider 2011), and improvements in organizational skills and research skills (Eichenlaub et al. 2011) have been documented among students using tablets.

In addition to general improvements in student performance, tablets can have a significant

positive academic impact on students with disabilities. Henderson, Gibson, and Gibb (2013) evaluate the use of tablets by higher education students with physical disabilities (sight, hearing, motion, etc.) and with nonphysical disabilities (learning disability, autism spectrum disorder, etc.) and found that tablets can assist such students in a range of academic tasks; in addition, they found that students with physical disabilities strongly preferred tablets over laptop computers, although students with nonphysical disabilities preferred laptops. Ehrlich and Vance (2015) demonstrate how tablets can be used as interpretive devices for students with hearing disabilities and Hendricks et al. (2015) show that tablets can help students who have suffered brain injuries to prepare for a career.

Overall, there is significant evidence thus far to conclude that the adoption of tablets can bring academic benefits from multiple avenues. Improvements in student academic performance have been noted for a range of skills and demonstrated through improved assessment scores. Combined with the positive perceptions students hold of the technology, it is not surprising that initial resistance has lowered and a growing number of faculty are taking interest in the technology and also exhibit positive perceptions of tablet use in higher education.

Implementation Strategies

Despite the many implementation successes described in the literature, numerous difficulties with implementing a tablet program have also been identified; Mang, Brown, and Piper (2017) list resistance among students and faculty to adopting a new technology, the provision of sufficient wireless bandwidth, and the cost of providing tablets to students as barriers to successful implementation of a tablet program. In order to assess the effectiveness of implementing a tablet program in a higher education institution, Hargis, Cavanaugh, Kamali, and Soto (2013) develop a survey instrument which can be replicated at institutions looking to evaluate the success of their own tablet programs.

For faculty and institutions interested in implementing a tablet program, a broad literature now exists providing guidance at each step of the implementation process, from tablet selection, to information technology requirements, to in-class activities. Reflections by early adopters helped to shape the experiences of later trials of the technology, yielding a large array of pedagogical innovations in the humanities, social sciences, and sciences. Early failures of tablet adoption have led to mitigating strategies to tackle both student and faculty rejection, so that faculty and institutions now considering the adoption of a tablet program can experience greater success with its implementation.

Numerous strategies for implementing tablet technology in higher education classrooms have been proposed. While some studies have focused on broad recommendations, others have focused on implementation within specific disciplines. For academic programs which consider mandating the use of a tablet, an implementation strategy is a critical component to ensuring that students find purpose in the device. Early attempts to use tablets, such as those documented in Fischman and Keller (2011), Keller (2011), and Wieder (2011), were not successful as students ultimately rejected tablets in favor of laptops; lessons learned in those trials helped to inform later trials of the technology including Mang and Wardley (2012) which provides some of the earliest general recommendations on the creation of a tablet program in higher education.

Mang and Wardley (2012) provide six recommendations for faculty including knowing the details of the operating system, deciding early how to use the technology in class, working closely with the institution's information technology department, making the tablet an integral component of the class, describing the benefits and features on the first day, and carefully considering the method of tablet distribution to students. Anticipating that some students will experience technical difficulties, they note that it is important for student perceptions of the device that the instructor and the institution be prepared to offer timely advice and assistance. Anticipating that some students may be either unenthusiastic or

openly resistant to the technology, Mang and Wardley (2012) advocate for purposeful and well-explained usage of the device to manage student expectations.

To aid faculty in understanding the benefits and drawbacks of the technology, and in determining how best to make use of the technology in class, Dennen and Hao (2014) develop the M-COPE framework focusing on mobile affordances, conditions, outcomes, pedagogy, and ethics as the key elements in designing a higher education curriculum that incorporates mobile devices. They identify productivity, flexible physical access, capturing and integrating data, and communication and collaboration as chief benefits afforded by the use of mobile devices. They further identify learner preparedness, environmental suitability, time, and disruption of existing learning patterns as key conditions which may impact the successful use of mobile technology. Dennen and Hao (2014) emphasize choosing a pedagogy that supports desired learning outcomes and advise faculty to be aware of potential ethical issues arising from device usage such as socioeconomic conditions affecting the type of device(s) students may have access to.

Numerous pedagogical approaches have been taken when implementing tablets across a course or an academic program for the purposes of improving information literacy; for example, Brooks (2015) recommends using connectivism, a philosophy that emphasizes a learner's ability to form connections between networks of information sources (see Siemens 2005), as a guiding approach to designing information literacy skills building tasks for students using tablets. Such tasks involve searching for and evaluating the usefulness of various types of information. Moore, Black, Glackin, Ruppel, and Watson (2015) use a process-oriented guided inquiry learning (POGIL) model to integrate tablets into team-based exercises in which students develop information literacy skills by performing tasks designed to locate, use, and evaluate information. Mang, Brown, and Piper (2017) describe the co-implementation of a tablet program with a "Common Book" program, another recent

pedagogical innovation that integrates a single work of fiction or nonfiction into a variety of courses and/or extracurricular activities within an institution. They describe how the tablet program can be combined with a Common Book program to improve students' information literacy skills across a range of categories identified by Doyle (1992) including using tablets to search for information related to themes presented in the book and sharing the information with fellow students.

Additional general suggestions for the implementation of tablets into higher education classrooms include the use of quick response (QR) codes to index course content, whether stored on a learning management system or linked to an external resource, so that students with a tablet can quickly navigate to relevant information (Husbye and Elsener 2013), and the development and distribution of tablet-formatted lecture slides which specifically include space for students to handwrite additional notes on the tablet during the lecture as well as the use of in-class electronic quizzes (Mang and Wardley 2012).

Much work has been done to provide discipline-specific recommendations for tablet implementation. In the field of teacher education, Nguyen et al. (2016) develop a three-pronged approach to using tablets to train aspiring teachers: enhancing personal productivity, increasing collaboration in coursework completion and between faculty and students, and applying these new technology-based skills when teaching children. Furthermore, they provide an overview of various accessibility features of a tablet device, including available support systems for students with vision, hearing, physical, or cognitive disabilities, which have implications both in the instruction of aspiring teachers and for the future careers of teaching graduates using the technology to instruct youths. Marín et al. (2016) recommend a range of activities for teacher education programs including communication, collaboration, teamwork, video and photo editing, music creation, media playback, and social networking services that can be accomplished using tablets; they note that these activities impart new

skills to aspiring teachers and improve the learning experience.

Within the sciences, Rosenthal and Eliason (2015) discuss the implementation of tablets in a university physical health and education program; they develop a "pedagogy wheel," a graphical display based on Bloom's taxonomy (Bloom et al. 1956) which maps learning objectives in physical health and education to specific mobile applications that can be used, and specific activities that can be performed, on a tablet. Rosenthal and Eliason (2015) discuss methods to pair assessment with specific learning objectives across a range of physical health and education classes making use of tablet technology and specific mobile applications, particularly in laboratory exercises. Hesser and Schwartz (2013) also describe potential uses for tablets in laboratory classes; they recommend specific mobile applications that can be downloaded to the tablet for learning management, document storage, and chemistry simulation in order to eliminate all paper-based materials within a university laboratory class. Additionally, Morris, Lambe, Ciccone, and Swinnerton (2016) make recommendations for specific activities and mobile applications for tablet devices in neuroanatomy laboratory sessions. Furthermore, Stone (2016) describes implementing tablets in computer science classrooms including activities such as building flowcharts, writing computer code, and creating information products based on collaborative research.

Within the humanities and social sciences, Brewer, Begleiter, Anderson, and Issacs (2015) discuss how to use tablets in a political science class by encouraging students to use social media to research and connect with political campaigns. Gabarre, Gabarre, Din, Shah, and Karim (2014) show that tablets can be used to assist students with translation exercises in a foreign language class, while Brown, Castellano, Hughes, and Worth (2012) and Gitsaki and Robby (2014) demonstrate how tablets can be used to teach English. Marín et al. (2016) discuss a variety of uses for tablets in music education such as recording, editing, and processing exercises.

Once a decision has been made to adopt tablets across a program, Drouin, Vartanian, and Birk (2014) recommend the development of a community of practice, an information sharing network among faculty; they design and explain how to implement a community of practice model to assist faculty through the adoption process, emphasizing regular meetings of both small and large groups of faculty who can share their experiences with the technology, offer suggestions on in-class use, offer problem-solving advice, and determine best practices for using the device.

These early studies offer some ways to overcome resistance to change at the organizational level through effective implementation strategies. Communicating a clear vision of why the change is needed and what direction the change will take can allow faculty, students, and administrators the opportunity to embrace the introduction of tablets. Offering champions that can help to lead others during the change process can let faculty and students know specifically what is expected of them and provide training and support for any identified gaps in knowledge or skills. Establishing a system of incentives for students and faculty can also be helpful, so faculty and students see the benefits of learning the skills needed to succeed. Identifying the best way and timing to make the change must vary according to the realities of the workplace. Evaluating and modifying resources and supports based on feedback are also an effective way to remove barriers.

Conclusion

The use of tablet technology in higher education offers the potential to strengthen students' learning transfer and workplace technology-based competencies. Implementing tablet technology programs has recently emerged as a valuable way of developing these competencies. Improvements in information literacy, collaboration, and research skills have all been documented. Furthermore, tablets have been

shown to improve academic engagement among students. Nevertheless, the complexities of structuring and delivering a tablet program are noteworthy as are the concerns of faculty, students, and administrators who are involved in supporting these programs.

Success in implementing a tablet program is not guaranteed. Despite generally high rates of satisfaction with the device among both students and faculty, it is clear from examining both the earlier (failed) trials and more recent successful trials of the technology that strong preparation for the implementation of the device is a key prerequisite to success. Without the removal of barriers during the implementation process, tablets will not be used to their full potential. Effective curriculum design with a clear strategy for using the device in class, clear explanation of the device's purpose, and out-of-class technology support are common features of successful tablet programs. When the device has been seen to be a hindrance, when its purpose has not been fully explained, and when useful activities to perform with the device have not been designed, tablet implementation has proven less successful. The key issue of off-task distraction identified by both students and faculty is one significant drawback to technology use that needs to be carefully considered during implementation.

As the use of tablets in higher education has expanded, new suggestions for implementation in the humanities, social sciences, and sciences have emerged, providing new avenues for further experimentation and scholarship. The positive benefits accruing to tablet use have been well documented leading to a further proliferation of tablet programs at higher education institutions.

Toowoomba, QLD, Australia

²School of Teacher Education and Early
Childhood, University of Southern QLD,
Brisbane, Australia

³University of Tasmania, Hobart, TAS, Australia

This entry describes the characteristics of professional development programs (PD) to enhance teacher educators' (teachers of pre-service teachers) knowledge of technology-integrated teaching which subsequently facilitates their effective use of technology in the teaching in initial teacher education institutions. There are challenges with using technology in teaching, but relevant PD can help teacher educators to overcome these challenges for the effective use of technology in teaching. The description is drawn upon data from an intervention study involving designing and handling PD to assist mathematics teacher educators in integrating technology in their teaching and illustrating the characteristics of effective PD for teacher educators in tertiary settings. The entry is organized in five sections. It begins with a description of the importance of technology in higher education followed by an illustration of teacher education that highlights the challenges for technology-integrated teaching. The third section illustrates the characteristics of effective PD for technology-integrated teaching in initial teacher educations. The fourth section suggested the characteristics of effective PD programs for teacher educators and implications for preparing pre-service teachers. The conclusion summarizes the findings presented in this entry. Some of the study papers referred to concerned PD programs for school teachers that were included because of their relevance to teacher educators at initial teacher education

institutions. The following section highlights the importance of technology in higher education.

Importance of Technology Use in Teaching

Using technology in teaching can lead to significant positive outcomes for student learning and also bring significant benefits to teachers (e.g., Ayub et al. 2010; Bu and Haciomeroglu 2010). This has motivated university, college, and school teachers to integrate technology into teaching to achieve better learning outcomes. Technology can support constructivist pedagogy, as students use technology to explore and reach an understanding of concepts (e.g., Bu and Haciomeroglu 2010). Technology-based learning environments can provide opportunities for active learning that can enable students to perform at higher cognitive levels, support their effective learning, and promote scientific inquiry and conceptual change. For such purposes, a wide range of virtual educational environments and applications are available that offer a variety of possibilities for both students and teachers. Increased availability of technology resources, however, does not guarantee increased rates of effective integration of technology (Getenet et al. 2016; Hew and Brush 2007); instead, the integration of technology tools into teaching demands specific skills of teachers that can be enhanced through professional development [PD] (Niess 2011). In addition, there are various factors which can inhibit technology's practical use in teaching. The following section describes these factors.

Teacher Education and Challenges for Technology-Integrated Teaching

It is a common misconception that access to technology alone motivates teachers to apply it in their teaching. On the contrary, studies (e.g., Getenet et al. 2016; Hennessy et al. 2010) have shown that among the most significant barriers to the use of technology are teachers' motivation and confidence, technological literacy and confidence

levels, pedagogical expertise related to technology use, and understanding of the role of the teacher when integrating technology. Teachers need to learn how to use technologies in their teaching. A lack of technical support of expertise in the schools and teachers' lack of expertise in using technology are reportedly the most prominent factors hindering teachers' readiness and confidence in using technology (Looi et al. 2008). While there were some notable exceptions to this generalization, it seemed that computer laboratories in schools and higher educational institutions stand idle for much of the time (Tella et al. 2007), but as more classrooms become technology-rich environments, it is less likely that teachers will perceive the lack of access to technological resources as a barrier to effective technology integration.

The other major barrier to effective technology integration is teachers' knowledge of technology and pedagogy extended into the domain of teaching with technology that is teachers' technological pedagogical and content knowledge [TPACK] (Koehler and Mishra 2009). The idea of pedagogical content knowledge combined with technical knowledge is likely to take the place of lack of technology resources as the primary determinant of the extent to which technology is integrated into teaching (Niess 2011) because teaching effectively with technology requires teachers to have TPACK. Niess (2011) emphasized the importance of teachers having integrated knowledge of technology, pedagogy, and content for effective teaching through technology. The ability of teachers to coordinate content, pedagogy, and technology depends mainly on the way teachers were taught to integrate technology into teaching and how these components are acquired in PD sessions (Koehler and Mishra 2009). Hence, insufficient PD to support teachers to integrate technology is another barrier, which has implications for school teachers as well as teacher educators (teachers of pre-service teachers), including the ongoing need to equip them with the necessary skills to integrate technology in teaching.

Along with teacher educators having the skills and knowledge to integrate technology in their own teaching of pre-service teachers, they also

need to prepare pre-service teachers to integrate technology in their teaching using a variety of different approaches. It is not sufficient to teach the next generation of pre-service teachers in the ways their educators were taught. Pre-service teachers must encounter the effective integration of technology in the normal course of their learning at initial teacher education institutions, particularly as technology is becoming increasingly available in schools. Albion, Tondeur, Forkosh-Baruch, and Peeraer (2015) recommended that teacher educators become familiar with what to do with these new tools and digital media and create meaningful learning opportunities for pre-service teachers even though they themselves have not experienced such opportunities. Researchers such as Valtonen et al. (2015) and Tondeur et al. (2016) have made many recommendations about effective ways of supporting pre-service teachers to teach using technology, and ensuring that pre-service teachers see technology being modelled by educators in their own teaching is one means. When teacher educators act as models, pre-service teachers can see the importance of developing and using technology-based lessons in their own teaching (e.g., Ertmer and Ottenbreit-Leftwich 2010). Recent trends in teacher education have emphasized the importance of learning with technology rather than learning about technology (e.g., Tondeur et al. 2016; Valtonen et al. 2015). This means that teacher educators need to use technology to enhance pre-service teachers' learning of mathematics rather than teaching isolated skills using specific computing applications (e.g., word processing, database, spreadsheets, or hypermedia) or merely learning a specific programming language. Drent and Meelissen (2008) found that a teacher educator who uses technology for the enhancement of the learning process of pre-service teachers shows those pre-service teachers how technology can be used in their future teaching. Nevertheless, many teacher educators lack the knowledge needed to do so.

One way of improving teacher educators' skills in integrating technology in their teaching is through PD programs from which teacher educators can gain an understanding of the use of

technology and ways to change their roles and practice in their teaching accordingly. Emphasizing teacher educators' PD is a key factor in tertiary education to effectively use technology to enhance teaching and learning (Hennessy et al. 2010). Drent and Meelissen (2008) showed that participating in ongoing PD helps teacher educators to acquire the knowledge needed to integrate technology in their teaching.

Studies investigating PD programs aimed at the use of technology in teaching have indicated that such programs are often focused on the acquisition of basic skills in the use of technology and typically taken place in training centers in the form of seminars (e.g., Voogt et al. 2012). With few exceptions, therefore, PD programs for technology integration in teaching lack adequate duration, continuity, and pedagogical direction (Schibeci et al. 2008). In addition to the need to focus on the pedagogical use of technology, there is a gap in supporting teachers in relation to technology use in teaching in ways that are based on subject-specific content and pedagogies (Voogt et al. 2012). The following section describes the characteristics of effective PD programs that focus on integrating technology in teaching.

Characteristics of Effective Professional Development

Although PD programs are essential to enhancing teacher efficacy, they are often organized in traditional and prepackaged forms. However, traditional models of PD have not been particularly successful in helping teachers to find ways to integrate technology into their teaching, and teachers are not comfortable with such PD programs. In recent years, effective PD has been considered a long-term process that includes regular learning opportunities and experiences planned systematically with the involvement of participants. Traditional PD programs have been criticized for being ineffective because they are often organized as fragmented and superficial workshops or seminars that do not allow for participants' involvement in the design process. On the other hand, PD programs which emphasise on

the importance of involving participants in a PD program design process, consider team formation, encourage collaboration and value the role of facilitators are increasingly regarded as effective PD programs (Getenet 2015).

In addition, more effective PD program strategies are designed to move beyond the acquisition of basic technology skills to conduct technology-focused lessons and the pedagogical aspects of technology use and eventually to help teachers to adopt appropriate technology integration in their teaching. Technology-related PD programs need to be school-based, collaborative, and continuous (Schibeci et al. 2008; Hea-Jin 2007). Such PD programs are likely to help teachers at any level exploit additional learning opportunities afforded by technology and begin to make fundamental changes to their pedagogy (Schibeci et al. 2008) because they are supportive of acquiring the appropriate skills for using technology in teaching (Kalogiannakis 2010). Schibeci et al. (2008) argued that the complex process of preparing teachers to use technology is best supported by PD programs that focus on pedagogy and adult learning rather than short-term training. In addition, O'Bannon and Judge (2004) suggested that PD programs can be more effective when viewed from a whole school approach, which encourages change over time.

According to Lavonen et al. (2009), informal discussions in small groups and continuous support are vital aspects of effective PD in general. Similarly, McKnight, O'Malley, Ruzic, Horsley, Franey, and Bassett (2016) emphasized the importance of group formation, collaboration, and ongoing practices as essential components of effective PD programs. In addition, rehearsal of classroom practices, active involvement of facilitators, and thoughtful and informed decisions about the context are essential aspects of effective PD programs. Van den (1999) suggested three advantages of scaffolding a PD program with exemplary materials which are creating a clear understanding of how to translate the new teaching into classroom practice, provide support for the execution of technology-integrated lessons, and stimulate teacher educators to practice the intended teaching approach.

Hea-Jin (2007) developed a model of an effective technology-related PD program to enhance teachers' conceptual understanding and pedagogical strategies and the effective use of technology. The design of that study incorporated four essential components of effective PD programs: systemic support, knowledge-building workshops, classroom implementation and application, and building a team. Hea-Jin argued that in order to be effective, teachers need sustained and ongoing PD to learn, analyze, and reflect on new concepts and the use of technologies for effective student learning. Real classroom experience, collaborative work, and systematic support for effective PD are also important aspects (Valtonen et al. 2015).

Recent studies, therefore, underpin a paradigm shift in PD program strategies from traditional one-stop training, workshops, and the like toward more collaborative models. Traditional PD programs, in general, have been criticized for resulting in the surface-level implementation of instructional principles as opposed to deeply rooted changes in practice. In contrast, collaborative models of PD tend to engage teachers in joint inquiry about teaching as a means of shifting practice. Furthermore, collaboration can be realized through the formation of teams of teachers engaged in successful collaborative PD (Looi et al. 2008).

PD Program Strategies and Teacher Educators

Despite the wealth of commentaries on teacher education programs, there is little empirical research focused on teacher educators themselves (Beswick et al. 2012; Beswick and Goos 2018; Ottenbreit-Leftwich et al. 2012). A question seldom discussed in the literature concerns the extent of what teacher educators need to know in order for pre-service teachers to learn from them. Although teacher education is considered necessary for the quality of teachers, very little is known about the professional quality of teacher educators. For example, Beswick and Goos (2018) showed that mathematics teacher educators' knowledge is under-researched area, but

their knowledge is an indicator of pre-service teachers' quality. Hence, there is a need to study teacher educators and the role of the teacher educators and to rethink the kinds of knowledge and skills teacher educators ought to have for effective teaching of pre-service teachers. There are few studies on PD programs offered to teacher educators with a few of these focused on the PD program needs of newly appointed teacher educators, the effectiveness of PD program activities carried out for the teacher educators, and the difficulties they experience (Kabakci et al. 2010). A desirable professional competency of teacher educators that has been identified is the ability to model explicitly for pre-service teachers the thoughts and actions that underpin their teaching approaches (Loughran and Berry 2005). Hence, there is a need for teacher educators to participate in PD programs to help them effectively use technology in their teaching and to enable pre-service teachers to learn about using technology from teacher educators practice.

Teacher educators need ongoing PD programs in the effective use of technology in order to keep up with the changes and developments in technology and to be able to model appropriate use of technology for teacher candidates (Kabakci et al. 2010). Little is known about how best to assist teacher educators in using technology to influence pedagogy and content in a particular context. In a review of PD programs on technology use in teaching (Getenet et al. 2016), it was suggested that PD programs for teacher educators emphasize the interplay of technology, pedagogy, and content knowledge for effective teaching with technology. The availability of many different technologies that can facilitate teaching and the challenge of keeping up to date with new emerging technologies means it is unrealistic to attempt to equip teacher educators in relation to all available technologies and pedagogies. Nevertheless, there is a range of pedagogical practices that can facilitate the learning of students (e.g., problem-solving, inquiry learning, etc.). PD programs that focus on these strategies can enhance teacher educators' knowledge for teaching with technology and help them design appropriate pedagogy and technology for use in their teaching. Teacher

educators in initial teacher education institutions require PD programs which are flexible to suit for their busy time schedules. The following characteristics of the PD program developed by Getenet (2015) are relevant to teacher educators generally. They are drawn from an intervention study involving designing and developing PD to assist mathematics teacher educators in integrating technology in their teaching in tertiary settings.

Context-Based

Understanding context can help PD program designers to gain a better picture of teacher educators' needs and suggest context-based PD program guidelines (Vangrieken et al. 2017). Context is a collection of factors that can influence the design of the PD program for a particular group or be delivered in a particular environment (Smith and Ragan 2005). A context analysis plays a vital role in providing rich data for designing real examples, practical content, and scenarios (Vangrieken et al. 2017). According to Wood et al. (2011), for example, considering and analyzing the context in which the PD program is to be implemented is an essential component of an effective PD program. Smith and Ragan (2005) suggested three themes in analyzing the context: learner analysis (teacher educators), learning context analysis, and learning task analysis. Learners' characteristics and characteristics of the learning context (the physical place in which the PD will be delivered) can be used to suggest the learning tasks which constitute a PD program (Smith and Ragan 2005). Table 1 shows the three aspects of context analysis along with guiding issues to be considered as suggested by Smith and Ragan (2005) for effective PD program design.

According to Smith and Ragan (2005), the analysis of learners' characteristics is an important aspect of instructional design in general and PD program design in particular. In particular, the analysis of learners' specific prior knowledge is a crucial feature.

As part of the context analysis, the environment in which the PD program is to be conducted should be analyzed to gain insight into the existing conditions in relation to the PD program. According to Smith and Ragan (2005), the

Teacher Education and Professional Development for Technology Integrated Teaching, Table 1 Context analysis aspects and guiding issues

Context (Smith and Ragan 2005)	Guiding issue (Smith and Ragan 2005)
Analyzing the learners	Learners' general characteristics Learners' prior knowledge Learners' age Learners' beliefs toward the subject matter Learners' preferences, attitudes, interest
Analyzing the learning context Need assessment	Determine whether there really is a problem Determine whether the cause of the problem is related to educators' performance due to a particular problem Determine whether the solution to the achievement/performance problem is learning Determine whether the instruction for these learning goals is currently offered
Describing the learning environment	Are there existing curricula into which this piece of design must fit? What hardware is commonly available in the potential learning environment? The characteristics of the classes and facilities that will use the new PD program results The characteristics of the school system
Learning task analysis	Write learning goals Conduct an information-processing analysis of that goal Conduct a prerequisite analysis Determine the type of learning of the prerequisites Write learning objectives for the learning goals

analysis of the learning context involves two major components including the substantiation of a need for the PD program and a description of the learning environment in which the PD program will be implemented. After understanding the learning context and the learner context, the next step is to identify an appropriate PD program to address the context. Smith and Ragan (2005) indicated that the principle steps in performing a learning task analysis are, for example, to write learning goals, conduct a prerequisite analysis and determine the type of learning of the prerequisites, and write learning objectives for the learning goals.

In summary, investigating the characteristics of context for a PD program design process makes the content concrete and realistic and makes it more likely that the PD participants will understand how their learning can be applied in the classroom teaching.

Team Formation

Team formation is considered a suitable PD program strategy (Looi et al. 2008) on the assumption that knowledge is dynamically constructed as teachers conceive of what is happening to them, talk, and reflect. Group activities have been shown

to benefit teacher educators by providing opportunities to share ideas with colleagues (McKnight et al. 2016). Team formation in PD programs is effective when four critical characteristics are present and contribute to the proper functioning of the team in supporting members' efforts to integrate technology into their teaching. The team formation characteristics are active involvement, collaboration, positive attitude and a clear and shared vision of the team (Vangrieken et al. 2017).

Team formation can be used as a strategy to encourage teacher educators to collaborate with colleagues on an ongoing basis and adapt the PD program to suit participants' particular schedules. Studies (e.g., Looi et al. 2008, Lavonen et al. 2009) have suggested that the formation of small teams is helpful in supporting teachers to talk and reflect upon what is happening in the classroom on a continuous basis. The collaboration within the teams is particularly enhanced by incorporating them in a PD program as informal component of the PD. Looi et al. (2008) indicated that informal discussion is helpful to dynamically construct knowledge and deepen knowledge while the PD participants talk about what is actually happening in the classroom and can provide teacher educators with the opportunity to share ideas with their colleagues.

Informal and Flexible PD Arrangements

According to Lavonen et al. (2009), an informal discussion in small groups and continuous support are vital aspects of PD. Informal or flexible PD program arrangement, however, has not been mentioned as a characteristic of effective PD programs in these studies. Nevertheless, informal arrangements are an essential feature of a PD program to support teacher educators to integrate technology into their teaching of mathematics successfully. Participating in informal PD perhaps as part of a more structured program is preferred to formal PD program that requires teacher educators to regularly attend large group sessions. PD programs structured around teacher educators' availability and that fit with their own schedules could be the best approach to address teacher educators' tight schedules (Getenet 2015).

Looi et al. (2008) indicated that informal discussion is helpful to dynamically construct knowledge and deepen knowledge while teacher educators talk about what is actually happening in the classroom. In addition, the informal setup can provide the teacher educators with the opportunity to share ideas with their colleagues and thereby create a continuous PD program. The teacher educators are likely to favor of a PD program based on their availability and one which fits with their own schedules. Three advantages of informal PD program arrangements are:

- It does not require the presence of all teacher educators at the same time.
- It facilitates easy discussions and collaborations with colleagues.
- It creates a feeling for the continuous PD program on participant teacher educators.

This arrangement facilitated the teacher educators' participation based on their available time, providing continuous involvement without being physically together (Getenet 2015).

Focus on Pedagogical Use of Technology

Studies suggest that effective PD programs move beyond the acquisition of basic technology skills (e.g., Hea-Jin 2007; Schibeci et al. 2008) to focus on the pedagogical use of technology. The lack of

PD focused on pedagogy associated with technology use can hinder teacher educators from integrating technology into their teaching. In addition to the need to focus on the pedagogical use of technology, there is a need for PD designed to support teachers to use technology in teaching in ways that are based on subject-specific content and pedagogies (Voogt et al. 2012). PD programs which focus on how technology, pedagogy, and content interplay in a classroom context for effective teaching are essential for using technology-integrated teaching. An emphasis on the pedagogical use of technology can facilitate teacher educators' creation of relationships between pedagogy, the selected content or concept, and the technology, thereby enabling them to apply their learning in their teaching. Such PD programs are imperative for developing an understanding among the teacher educators of technology integration with the pedagogy and content.

Exemplary Materials

Preparation of the exemplary material can provide the teacher educators with a point of reference to design their own technology-integrated lessons. According to Van den Akker (1999), there are three advantages of including exemplary material when designing a PD program. These advantages are (i) creating a clear understanding of how to translate the new teaching approach into classroom practice, (ii) providing a solid foothold for the execution of technology-integrated lessons that resemble the intended objectives, and (iii) stimulating teacher educators to practice the intended teaching approach. Exemplar material created and provided as part of the PD program can develop teacher educators' awareness of the possible use of technology in their teaching and the importance of their use of technology as a model for technology-integrated teaching.

Conclusion

Supporting teacher educators in technology integration through PD not only can enhance the quality of their teaching but also facilitate the preparation of pre-service teachers to be effective

in teaching with technology. This is because learning to use technology from their teacher educators' teaching was shown to be a more effective way of preparing pre-service teachers to use technology in their teaching than simply learning about teaching with technology. Designing PD programs for teacher educators requires consideration of various factors. This entry has highlighted the characteristics of PD programs that the teacher educators can benefit from not only in order to use technology their teaching effectively but also in order to prepare pre-service teachers to use technology in their teaching. The characteristics of effective PD programs for this purpose are that they are context-based, focus on the pedagogical use of technology, include team formation, are supported by exemplary material, and include an informal setup that can support teacher educators' effective use technology in their teaching.

The emphasis of PD programs on the pedagogical use of technology can facilitate the teacher educators' creation of relationships between the pedagogy, the relevant content concept, and the technology, enabling them to apply them in their teaching.

PD programs with these characteristics are especially relevant to those looking to improve teaching with technology with the teacher educators recognizing that this can influence pre-service teachers to use of technology. They are especially relevant to those looking to improve teaching with technology with teacher educators recognizing that this can influence pre-service teachers to use of technology.

Teacher Education, Thinking About ICT

Kelly Carabott and Amber McLeod
Monash University, Clayton, VIC, Australia

Synonyms

Digital technology; Trainee teachers

Introduction

There is a growing emphasis on digital competence as part of mainstream education, and teachers need to be prepared to teach it. ICT has been included in a growing number of national school curriculums in two main ways. School graduates need to be digitally competent in order to go on to further education or enter the workforce, so ensuring that students have an understanding of how to use ICT to communicate, collaborate, and create in a safe way is a clear part of many curriculums. In addition, digital technologies have been integrated into curriculums as part of teaching and learning of other subject areas in an effort to improve educational outcomes. Teachers, therefore, need to be instructed how to teach ICT but also to use ICT to teach subject content.

Educating student teachers about how ICT can be used in education involves more than

technological know-how. The pedagogical and content knowledge components of ICT in education are arguably more important. In addition, student teachers should not blindly use ICT but be given tools to critically evaluate the educational value of digital activities. Successfully incorporating ICT into education degrees requires student teachers to not only understand why ICT could be used to support learning and teaching across the curriculum but to also experience this (Tondeur et al. 2012). Many teacher educators do not have this knowledge or experience themselves (Tondeur et al. 2012), and current embedding practices range from a transmission lecture approach (didactic) to a combination of transmission and hands-on learning (didactic and constructive) during workshop style tutorials. Employing experiential learning where student teachers are required to learn using ICT themselves is seen as an effective way of including ICT in teacher education.

The Importance of Creating Digitally Competent Teachers

Many assumptions have been made about what digital competence means, the level of competence students and student teachers already have, and how much explicit instruction is required to create a digitally literate society. The idea of the “digital native” (Prensky 2001) persists in universities, as evidenced by the push to move education into online environments. However, while technology is embedded in young people’s lives, their skills are not uniform, and they use a limited range of established technologies (Jones et al. 2010; Margaryan et al. 2011). Completion of school does not necessarily result in uniformly digitally competent students. In Australia, the most recent results of the Australian National Assessment Program indicate that the percentage of Year 10 students reaching proficiency level for digital technologies is concerningly low (52%) and show a statistically significant drop in digital competence across all cohorts of students since testing began in 2005 (National Assessment Program 2014). The drop in the digital competence of school students suggests current methods of educating student

teachers about ICT are not as effective as hoped, with many student teachers not reaching the levels of competence envisaged to deliver the curriculum. Universities are grappling with the most effective way to achieve this. While the best method of embedding digital content in education units is not yet clear, the importance of using considered pedagogical practice when educating student teachers to exploit technology appropriately in their teaching is.

Initial Teacher Education Content

Initial teacher education is responsible for ensuring that student teachers are ready for the complexities of their future workplace (the classroom). Thus, initial teacher is tasked with ensuring student teachers are digitally competent and also preparing them to teach digital competence. This includes not only technological, pedagogical, and content knowledge but the ability to critically assess ICT. Future teachers need to be competent and confident enough to teach ICT and teach with ICT.

Curriculum Expectations

Through curriculum documents, governments around the world have mandated how digital competence and the use of ICT for teaching and learning should be incorporated into the school environment. Student teachers need to be made aware of school curriculums through their teacher training.

For example, in Australia, digital technologies are taught to Australian school students in two ways (Australian Curriculum and Reporting Authority 2018). First, there is a dedicated technologies learning area made up of two strands: design and technologies and digital technologies. Specific examples of the strand include computation thinking and spreadsheets. Second, the curriculum recognizes ICT as a general capability, to be embedded across all subject areas. All teachers are expected to incorporate this general capability in their lessons, for example, using a common digital tool with subject content, such as using Excel to make a graph, improving literacy with

**Teacher Education,
Thinking About ICT,**
Fig. 1 SAMR model
(Puentedura 2010, p. 2)

eBooks, or using Google maps to teach map reading skills.

In other countries ICT is represented in the curriculum in a much more straightforward way. For example, Scotland and Canada include ICT across all curriculum areas, while the UK curriculum includes ICT as a separate subject. Interestingly, Japan does not have a strong emphasis on ICT, and in the Netherlands, each school is able to determine how ICT is incorporated into the curriculum. What is clear is that for the majority of countries, integrating ICT in everyday teaching practices is a priority and something that all future teachers will need.

Purposeful Use of Technology

Student teachers also need to be made aware of the research on educational technology. Findings suggesting the effectiveness of using ICT in education are inconclusive (Organisation for Economic Co-operation and Development 2015) and should alert student teachers that careful assessment of the pedagogical worth of digital technologies, and how they are to be used, needs to occur before considering employing them in class. Therefore, student teachers need to be exposed to a number of models which can help them critically assess the usefulness of ICT to deliver specific content. One such model is the SAMR model (Puentedura 2010) which describes four categories of tasks: substitution, augmentation, modification, and redefinition. At the substitution level,

a digital resource is a duplication of the traditional equivalent. For example, a digital textbook that is an exact replica of a paper textbook with no added features. At the augmentation level, there is functional improvement, such as links to videos, extra resources, or augmented reality. Modification suggests that the digital resource has been redesigned significantly, for example, the textbook operates as a blog and students from around the world can add comments. Redefinition suggests a task that has been designed in such a way that it could not be done without technology, for example, students create an original online textbook, including videos, based on their own research (Fig. 1).

Digital Competence

Digital competence is more than just being able to turn on a computer. In addition to knowing how to operate ICT tools, there are many other facets of digital competence. Ferrari (2013) states that people need to have the following five key competencies in order to live within a digitally saturated twenty-first-century world.

Information:	Identify, locate, retrieve, store, organise and analyse digital information, judging its relevance and purpose.
Communication:	Communicate in digital environments, share resources through online tools, link with others and

- collaborate through digital tools, interact with and participate in communities and networks, cross-cultural awareness.
- Content-creation:** Create and edit new content (from word processing to images and video); integrate and re-elaborate previous knowledge and content; produce creative expressions, media outputs and programming; deal with and apply intellectual property rights and licences.
- Safety:** Personal protection, data protection, digital identity protection, security measures, safe and sustainable use.
- Problem-solving:** Identify digital needs and resources, make informed decisions as to which are the most appropriate digital tools according to the purpose or need, solve conceptual problems through digital means, creatively use technology, solve technical problems, update one's own and others' competences. (Ferrari 2013, p.4)

As Koehler and Mishra (2009) point out, “teaching is a complicated practice that requires an interweaving of many kinds of specialized knowledge” (p. 59). It is not enough for student teachers to be digitally competent themselves; teacher education programs should provide student teachers with an understanding of the curriculum content, the pedagogical understanding to employ considered and purposeful use of technology for learning and teaching, as well as exposing them to a wide range of digital experiences. This is what Koehler and Mishra (2009) refer to in the TPACK model. This model, which has become an essential framework to guide ICT initial teacher education, suggests that

teachers need an understanding of how content knowledge (CK), pedagogical knowledge (PK), and technological knowledge (TK) converge to form technological pedagogical content knowledge (TPACK) in order to effectively incorporate technology into education (Fig. 2).

Social Considerations

Student teachers also need to be made aware of the social and institutional contexts they could be presented with (Koehler and Mishra 2009) including barriers to ICT integration within schools. Cultural attitudes among teachers, the wider community including parents, and the general population can greatly impact upon the success of digital technology integration in schools. First-order barriers are usually classified as those extrinsic to teachers and involve, among other things, access to equipment, time, training, and support, while second-order barriers are intrinsic and related to the teacher's underlying beliefs about teaching, learning and technology, their established practices, and willingness to change (Ertmer 1999). More recently, third-order barriers have been proposed by Tsai and Chai (2012) which describe the struggle teachers have with “design thinking” (the ability to create what is desired) which could be used to help overcome first and second barriers. Design thinking skills allow teachers to creatively adapt their teaching style and content for the differing social and institutional contexts of schools they encounter, as well as the students and classroom dynamics. For example, computational thinking can be taught with offline activities if digital technologies are not available and creative use of technology allows for lessons that include ICT in ways that do not compromise pedagogical beliefs. Tsai and Chai (2012) remind us that because technology advances and changes at such a rapid rate, there will always be barriers to integration, making design thinking that much more important.

Including ICT in Teacher Education

While there is a general consensus that digital competence, sound pedagogical and content

Teacher Education, Thinking About ICT,

Fig. 2 The TPACK model
(Koehler and Mishra 2009,
p. 63)

knowledge, and well-developed design skills should be developed through teacher education, the way these aspects are included in teacher education varies widely. In a number of universities, ICT inclusion mirrors school curriculums, where some institutions have included digital technology as a separate unit, while others have integrated it across the teacher education curriculum. There have been numerous studies which focus on the effectiveness of initial teacher in adequately preparing future teachers to use ICT and to teach using ICT effectively. However the research indicates that initial teacher education is not adequately preparing future teachers (Wang et al. 2014; Sweeney and Drummond 2013). The reasons why are varied and complex, and there is no single idea or strategy that can be applied across contexts.

The Complexity of Preparing Student Teachers

In 2012, Tondeur, Van Braak, Sang, Voogt, Fisser, and Ottenbreit-Leftwich conducted a systematic

review of the qualitative literature to analyze the key ideas and strategies which underpin the methods found to be most effective in preparing student teachers for technology integration. The following framework was constructed using the findings, which indicated 12 themes for student teacher preparation. The framework has several levels and represents a micro to macro approach, from student teachers, to the delivery of units in initial teacher education, to the wider institutional considerations (Fig. 3).

Surrounding the intentions of teacher education to prepare student teachers to use technology are the methods of including ICT in teacher education programs, and the how, where, and when of ICT integration are described at a unit level. Important considerations at this level include:

- Role models: Ensuring that teacher educators are modelling the effective use of ICT to teach unit content, for example, using technology to effectively employ literacy pedagogy

Teacher Education, Thinking About ICT, Fig. 3 The synthesize qualitative data (SQD) model to prepare student teachers for technology use (Tondeur et al. 2012, p. 141)

- Reflection: Allowing student teachers time to reflect on ICT use and their beliefs and attitudes toward technology for education
 - Instructional design: Consideration of the planning and preparation needed when incorporating ICT into teaching and learning
 - Collaboration with peers: The positive experience of collaborating and problem-solving in groups
 - Authentic experiences: Playing with the technology in order to learn unit content rather than just watching
 - Feedback: The move from traditional assessment to continuous feedback
- Moving out further into the third circle, we can gain a sense of the institutional elements that are important, the ability of the teacher education institution and staff to competently employ these methods:
- Technology planning and leadership: The university strategy for effective education for student teachers about technology integration and their own levels of ICT competence
 - Cooperation between and within institutions: The ways in which staff support each other and universities liaise with schools and outside organizations to ensure consistent expectations

- Staff development: The ways in which teacher educators are educated about using ICT as part of their own practice
- Access to resources: The resources available for teacher educators and student teachers to use

The outer circle of Tondeur et al.'s (2012) SQD model described efforts to change teacher education institutions in systematic ways in terms of resourcing, attitudes, and delivery of education in recognition that student teachers responded most positively to ICT education when theory and time for hands on practice were aligned. Considerations for systemic institutional change include changes to course structure, including how, when, and how frequently technology is highlighted in teacher education programs.

Institutional Considerations

Most initial teacher education courses globally are mandated by governments and other bodies who ensure that initial teacher education has met any accreditation requirements. For example, Australia, Scotland, the USA, and the UK have professional standards for teachers that must be met by both graduating teachers and existing teachers within the field. In comparison, the UK and US professional teacher standards do not explicitly make mention of ICT within schools to support learning and teaching, although it is in the school curriculum and teachers would still use ICT within their practice. As an example, Australian Professional Standards for Teachers (Australian Institute for teaching and School Leadership 2014) mentions ICT integration and the requirements of being able to use ICT to support teaching and learning explicitly in three standards and has implications for the others:

Standard 1. Know students and how they learn.

Standard 2. Know the content and how to teach it.

2.6 Information and Communication Technology (ICT): Implement teaching strategies for using ICT to expand curriculum learning opportunities for students.

Standard 3. Plan for and implement effective teaching and learning.

3.4 Select and use resources: Demonstrate knowledge of a range of resources, including ICT, that engage students in their learning.

Standard 4. Create and maintain supportive and safe learning environments.

4.5 Use ICT safely, responsibly, and ethically: Demonstrate an understanding of the relevant issues and the strategies available to support the safe, responsible, and ethical use of ICT in learning and teaching.

Standard 5. Assess, provide feedback, and report on student learning.

Standard 6. Engage in professional learning.

Standard 7. Engage professionally with colleagues, parents/carers, and the community (Australian Institute for Teaching and School Leadership 2014).

Course Planning

While there is no consensus on the best way to include digital technologies in teacher education, there are a number of issues that need to be taken into account when deciding upon the structure. The first consideration is whether to include ICT education as stand-alone units, content embedded across all or a number of units, or a combination of both. At which stage of initial teacher education ICT will be emphasized is another consideration. This is particularly important when only one stand-alone unit has been allowed for in the course structure. Sophisticated pedagogical knowledge does not emerge until the later years of initial teacher education, so a first year student teacher with little exposure to curriculum content and pedagogical knowledge may not grasp the importance of aligning pedagogy with content or be unable to envisage a use for technology beyond the examples they have been given (McLeod and Carabott 2018). On the other hand, a single ICT unit introduced in the later years of teacher education may mean that student teacher digital competence and confidence are not as high as imagined or that they do not fully appreciate the importance of ICT in the school curriculum. As such, single stand-alone ICT units are usually deemed as insufficient for student teachers to be adequately prepared for the complexities involved in integrating ICT (Lawless and Pellegrino 2007).

Student teachers do not arrive at university with a standard level of digital competence, and it is not something that can be developed within one 12-week unit. Not only do student teachers need time to play with ICT to develop their technological knowledge, they also need to build their understanding of digital competence and increase their confidence across a period of time. Increased exposure to ICT, both theoretical and practical, within teacher education units and degrees increases competence and enhances pedagogical understandings.

Where ICT is embedded across the curriculum, teacher educator digital competence becomes a significant factor. Academics, mirroring complaints from in-service teachers, suggest the digital content of their units is constrained by their own competence, interest, lack of time, and the resources available where the course is taught (Black and Smith 2009). Where ICT was embedded across units, student teachers have suggested that not enough was done to help them understand how ICT could facilitate their own teaching (Lei 2009). In one case study, Black and Smith (2009) found 46% of student teachers said that their initial teacher education had no impact on their digital competence. In the same study, only a third of student teachers believed their lecturers modelled embedding ICT well. In addition, “the

ICTs modelled rarely got beyond PowerPoint, while ‘academic’ staff seemed openly afraid or disinterested” (Black and Smith 2009, p. 21).

Unit-Level Approaches

The second circle of the SQD model (Tondeur et al. 2012) emphasizes the practical implications for teacher educators in relation to unit construction which should allow for role modelling, reflection, continuous feedback, collaboration, authentic experiences, and an appreciation of instructional design.

Traditional forms of university teaching involve the teacher educator standing up in front of the class and delivering the content in a didactic way, normally a lecture format. However, these didactic approaches may not be suitable for ICT development. This was evidenced by McLeod and Carabott (2018) who found that student teachers who only observed ICT being modelled were unable to imagine digital technologies as anything more than mere tokens used for motivation or engagement. This resulted in little change in the student teachers’ digital competence or understanding of its relationship with pedagogy or content knowledge.

Experiential learning is at the heart of teacher education as it is through both theory (units of study) and practice (professional practicum) that

**Teacher Education,
Thinking About ICT,
Fig. 4** Experiential
learning cycle. (Adapted
from Kolb (1984))

student teachers are educated. Kolb's experiential learning cycle involves forming abstract concepts, testing them in new situations, having a concrete experience, and observing and reflecting, which is then used to form further abstract concepts (Kolb 1984) (Fig. 4).

Experiential learning allows students to apply the knowledge or conceptual understanding gained to real-world problems. When the relevance of the experience is revealed, motivation, self-direction, and organization are increased allowing students to more effectively integrate new material with prior knowledge (Weinberg et al. 2011). Students are able to learn at their own pace or level, allowing differentiated learning (Beard and Wilson 2006) which is particularly important as student teachers arrive at university with varying levels of digital competence.

Some universities are employing experiential learning to help student teachers understand more about incorporating ICT in their lessons. McLeod and Carabott (2017) found that asking student teachers to create a digital object as part of a unit assessment task increased their understanding of the technological and pedagogical aspects of ICT in teaching in three main ways. Firstly, when creating with ICT was compulsory, as part of the assessment, student teachers increased their technological abilities with ICT – something they found challenging but rewarding. Secondly, student teachers were put in the position of learner which helped them understand problems their own students might face. Finally, and perhaps most importantly, student teachers recognized the opportunity to put theory into practice which gave them a deeper understanding of the unit content.

Student teachers participating in experiential learning have reported surprise at the level of thinking and engagement required in creating a digital object and that their attitudes toward using ICT in the classroom had changed as they realized the learning opportunities digital technologies allowed if used well (McLeod and Carabott 2018). When evaluating digital technologies using critical frameworks such as SAMR, the advantages and possibilities of digital technology

in education became easier for student teachers to imagine, and they gained a better understanding of why digital technologies are heralded as able to transform education. As well as deeper understanding of the technological and pedagogical aspects of ICT in the classroom, student teachers also showed a better understanding of how ICT was included in the curriculum and the expectations of teacher digital competence (McLeod and Carabott 2018). A greater intention to use digital technology for teaching and learning in their future classrooms was developed, and student teachers began to see beyond the superficial use of ICT, enabling them to engage in a deeper, experiential evaluation of technologies for learning.

Summary

It appears that ICT education is not being addressed adequately within initial teacher education as many student teachers are not reaching the levels of competence envisaged to deliver the curriculum (Lei 2009; Sánchez et al. 2011). Assumptions about the level of digital competence student teachers possess, no consensus on the best way to include ICT in course structure, and a lack of confidence among teacher educators as to how best ICT should be embedded at the unit level add to the confusion. In addition, while recognizing that sophisticated understanding of the interplay of ICT with pedagogical and content knowledge is required by student teachers in order to effectively enhance teaching, research on whether ICT benefits learning is still inconclusive.

In terms of content, ICT education covers a wide range of areas. In many school curriculums, teachers are required not only to teach ICT competence but to use ICT to enhance learning and teaching in other subject areas. To do this well, student teachers need to be exposed to tools that help them evaluate technology and its pedagogical worth when employed to teach subject content. Importantly, an ability to adapt ICT use to the sometimes less than ideal social and institutional contexts in which teachers find themselves needs

to be developed, along with an understanding and confidence that when faced with unknown digital technologies, an opportunity to model collaborative learning and risk taking is presented.

Initial teacher education institutions have a responsibility to ensure that course design reflects the standards set by government and professional teaching bodies. Based on an understanding that teacher education comprises both a theoretical and practical component, course design should include authentic, collaborative ICT experiences that allow the opportunity for feedback and reflection. Decisions need to be made about whether teacher educators should embed ICT for teaching and learning across a variety of units or whether one or more dedicated digital technology units should be included in course design, and the way in which the content is delivered – the balance of theory, role modelling and hands-on activities, optional or compulsory production of digital content, and the amount of time allowed for instructional design and reflection – all need to be considered.

Traditional didactic approaches, where ICT is role modelled to students without allowing them authentic experiences, could be replaced by participation in experiential learning, where time is made available for student teachers to experiment, reflect, and form new ideas, which leads to a deeper understanding of the potential of digital technologies in education. Student teachers who are required to put themselves in their learner's shoes and step outside their comfort zone to create, reflect, and problem-solve using digital technology begin to overcome the third-order barrier of lack of design thinking. The research suggests that when experiential learning using digital technology for assessment is used in addition to active embedding, student teachers are more likely to understand ICTE (and TPACK). A greater intention to use digital technology for teaching and learning in their future classrooms is developed, and student teachers began to see beyond the superficial use of ICT, enabling them to engage in a deeper, experiential evaluation of technologies for learning.

Teacher–Student Relationship: Definition, Role, Importance

Relationships between teachers and students are complex, and are usually defined within the school setting. Hence, they are many times referred to in a context that entails class management. These relationships are evident in the interactions between teachers and students, and focus on the social and emotional aspects of the learning environment. The interaction is based on actions of one party (either the teacher or the student), followed by a reaction of the other party. Conceptualizing teacher–student relationships, Hamre and Pianta (2006) noted that in addition to individual features, three components shape the relationships between teachers and

students: perceptions and beliefs, information exchange processes, and external influence.

Studies regarding teacher–student relationships and student engagement show that positive relationships were associated with higher levels of engagement, achievements, school attendance, and positive behavior, and with lower levels of suspension and dropout (Quin 2017). This indicates the central role of relationship between students and their teachers, especially with the latter’s role shifting from “a sage on the stage” to “a guide on the side.” As a result, formal traditional educational paradigms are making way to more contemporary modes, focusing on connecting teachers and students within a mentoring relationship that empowers them and addresses their well-being and their self-fulfillment as future citizens. Teachers are expected to fully and truly understand their students’ needs in the information era, utilize alternative teaching approaches, and establish authentic relationship with their students that reflect compassion and caring (Rodgers and Raider-Roth 2006).

Student–teacher relationship is key to students’ academic, social, and emotional development, and may altogether affect the educational environment (Sabol and Pianta 2012). They may also promote students’ feelings of safety, security, and belongingness, and eventually lead to higher academic achievements (Pianta 2006). Positive or negative teacher–student relationship might also influence teachers’ well-being and professional development. Hence, positive teacher–student connections and relationship are of importance to all concerned.

Digital media opens new opportunities for communication between teachers and students as an integral part of their relationship, including instant messaging services (e.g., WhatsApp, Snapchat, Facebook Messenger) and social networking sites (e.g., Facebook, Twitter, Instagram). Due to their popularity among children and teens (Anderson and Jiang 2018), teachers and instructors often use these platforms as a way to “meet” with their students wherever they are (especially beyond school timetable). The use of these platforms is changing the communication de facto between teachers and students, and as a result, has the potential to transform teacher–student relationship altogether.

Online Social Networks as an Extension of the Physical World

Redefining Online Social Networks

The history of social networking sites (SNS) is as old as the history of the World Wide Web. Websites identifiable as SNSs have been launched since the mid-1990s. However, the emergence of the Web 2.0 and the social media in the early 2000s have facilitated the use of SNSs to a point when they became mainstream (Boyd and Ellison 2007). Some SNSs are used specifically for predefined goals – e.g., professionalism (LinkedIn™), photographing (Flickr™), scholarship (ResearchGate™), or education (Edmodo™) – while others have been formed for general use – e.g., Facebook™, Twitter™, or Tumblr™. For many years, SNS are among the most popular websites.

From their early days and until today, SNSs are aimed at bringing people together, allowing communication, and creating communities unbound by geographic and demographic restraints. As these activities have been always part of the human society, and as people have always been part of social networks in the physical world, we refer to these services as online social networks (OSNs).

Over the years, OSN have shifted their emphasis from being focused on the individual user to being focused on the interactions and communication between the users. Indeed, in the early OSN – like MySpace™, Facebook™, and LinkedIn™ – the personal profile was the pillar of the network; hence, users dedicated time and efforts to present themselves. Indeed, early definitions of OSN highlighted the *profile* (that is, the feature that allowed users to construct a personal virtual identity) as a major component of these platforms. The most common definition, still in use, is that of Boyd and Ellison (2007), according to which social network sites are defined by three characteristics – the construction of a personal profile, the creation of a list of connections to other users, and the ability to traverse the web of connections – all of which are profile-centered. This definition seems to be inspired by the fact that most users of OSN in the early days were teenagers and young adults, and within this population, self-presentation is of high importance.

This shift of focus – from being profile-centered to being communication-centered – is evident in the design and features of today’s popular OSN. Platforms like Instagram™, Google+™, Pinterest™, or Twitter™ offer a relatively limited profile and are designed to focus more on the communication between the network members. Furthermore, with the growing use of smart phones and other Internet-connected portable devices, and as many people today are almost constantly connected to the Internet, social networking is regularly maintained through platforms and services not previously identified as social networking sites. Specifically, mobile instant messaging services – like Facebook Messenger™, Snapchat™, or WhatsApp™ – have a great social impact on their users, and are now including features that resemble those of social networking sites (e.g., profile, list of connections).

As the boundaries between mobile instant messaging services and OSN (which are heavily used via mobile apps) are now blurred, we would refer to both as OSN and revisit the definition of this term. Hence, we propose to define online social networks as Internet-based platforms that allow their members (individuals, groups, or organizations) to interconnect; the dynamic web of connections formed by the network’s members lays the foundation for immediate, multimodal communication; members of these platforms distribute content within the network and across networks in various ways.

Blurring of Traditional Boundaries in the Era of Online Social Networks

The use of OSN for teacher–student communication is reciprocally associated with school boundaries. The frequent, free, immediate communication allowed by OSN is associated with the blurring of traditional boundaries between teachers and students. Communication via OSN entails functional and social advantages. These include information exchange and exposure to new information, facilitating a positive social atmosphere, creating a dialogue among students, and supporting learning – all of which are directly connected to teacher–student relationship. Therefore, the transformation in teacher–student

communication may, in turn, affect teacher–student relationship at large.

However, this type of communication is not without challenges and obstacles. Obviously, teachers and students can communicate effortlessly, as individual network-members, in OSN. Nevertheless, as these platforms are somehow an extension of the traditional social network in the physical world, this communication is inherently highly social; that is, it is often characterized by self-disclosure and exposure. Considering communication between teachers and students, this may lead to a collision between the very nature of the communication and the traditional hierarchical order according to which teachers and students are not equal. Therefore, the issue of teacher–student communication via OSNs should be examined comprehensively, from a broad perspective that highlights its impact on traditional teacher–student roles, hence the importance of exploring teacher–student relationship in the OSN-era.

Policy

Teaching in the information era has become more complex as SNSs are becoming more popular. Teachers are expected to be updated and relevant for their students by their superiors, to be professionals in a media- and communication-saturated world, but also to be connected to their students and exhibit caring and concern for their well-being. This explicit policy is accompanied by possible implicit consequences, to weaken and even shake the existing traditional hierarchic structure of schools and the centralization of the education system as a whole.

Consequently, policymakers and teachers feel the need to re-define their educational role, shifting its emphasis from a formal-traditional instructional paradigm to a mentoring paradigm, thereby addressing the need to relate to students and assist them in their educational journey. This is especially significant in the digital era, in which information is accessible and available online. The popularity of OSNs created a setting in which the communication between teachers and students and the relationship between them

is extended; hence, they are considered platforms for establishing additional and even alternative routes of communication. However, while OSNs enable growth and flourishing of these relationships, they pose some challenges for all parties involved. Along with the requirement from teachers to know their students and address their personal needs, they are required by policymakers worldwide to avoid a situation in which boundaries between teachers and students, as well as boundaries between school and beyond, are blurred. This paradox is rarely addressed in policy documents or instructions, and is generally avoided. In some cases, teacher–student relationship on OSNs are prohibited altogether, or restrained to educational purposes only; this in turn contradicts the need to address the students as an individual with feelings and needs beyond the formal academic ones.

Some of these contradictions are a result of the digital divide between teachers and students that creates inequality between teachers and students with regards to digital literacy. This is also an issue addressed by policymakers, which in general encourage teachers to develop their digital literacies. By this, the probability of misuse of OSNs is reduced; however, the principle itself of the extent and modes of communication and the nature of teacher–student relationship as an outcome of this communication remains.

Furthermore, policy does not take into account the diversity of OSNs, in terms of their nature, their structure, and their privacy options, to name a few characteristics. When required to address the use of OSNs, what typically occurs is that policymakers' decisions are dependent and based on the most popular OSN at the time. For example, when Facebook was popular, policy was usually based on this specific OSN and its unique features, e.g., the availability of groups versus pages, the public versus private options, etc.; this dependency on one widely used network in decision-making regarding the use of OSNs for teacher–student communication may have excluded some essential aspects, for example, the connection feature (befriending vs. following).

Development During the Former Decade and Current State

School authorities and policymakers have been contemplating their position regarding student–teacher SNS-based communication. Education systems worldwide have adopted different educational approaches, often prohibiting teacher–student communication via OSNs altogether, sometimes as a means to avoid dealing with the complexity of the matter.

According to updated Israeli regulations, teacher and students are allowed, even encouraged, to communicate on Facebook following rules that cannot be enforced, e.g., only via a closed group, opened by the teacher, and communication only by using a separate Facebook profile (colliding with Facebook regulations), lacking any personal information. This demonstrates policymakers' confusion regarding OSN in education at large. Worldwide, policies span from banning teacher–student communication via OSNs, due to concerns of blurring boundaries between professional and personal lives, or the need to protect students from sexual harassment. These policies expect teachers and students to use only school-provided platforms.

Public discussion focusing on teacher–student communication via OSNs reflects the multifaceted nature of the matter, demonstrating, on one hand, the difficulty in adapting novelties in large-scale systems and organizations, and, on the other hand, indicating the tendency to utilize OSNs, which are anyway used for communication, also in schooling context. However, in many cases, policies are based on public opinion, local culture, and the nature of educational systems rather than on empirical evidence.

Evidence from Research

Although researched extensively in higher-education contexts, research on the use of OSNs for teacher–student communication in primary and secondary schools is lacking and insufficient, and is mostly focused on pedagogy (Tang and Hew 2017). The few studies that focus on teacher–student relationship in the context of OSNs indicate on advantages of this

communication, which include functional and social aspects, e.g., information exchange, facilitation of a positive social atmosphere, creation of dialogue, and support of learning (Pennings et al. 2014).

OSNs allow an enmeshment of teachers' personal lives and professional arena. They also enable students to bring their personal lives into a formal educational context (Greenhow and Askari 2017). This sets the basis for communication opportunities between teachers and students, which broaden the interaction between them regarding school matters, as well as other topics of interest. Doing so, it also sets new relationships between teachers and students. The penetration of teachers into their students' lives and vice versa is challenging, technologically, but also socially, psychologically, and for teachers – professionally.

The opportunities and possibilities of communication between teachers and students using OSNs are quite comprehensive. The communication becomes convenient and immediate, allowing both parties to practice real-time interaction, unbound to time or space limitations (Claessens et al. 2017). Hence, in spite of policy limitations in many countries, states, and districts, communication is evident and based on needs of both parties. The teachers connected to their students via OSNs are aware of policy limitations, but still communicate with their students (Asterhan and Rosenberg 2015). The reason is that both teachers and students appreciate and acknowledge the contribution of OSN-based communication to their relationship, and also to their students' academic outcomes.

Since OSNs are in use by both populations anyway, it seems only natural that students prefer this channel of communication over other, more formal possibilities, as private or public space for their social interactions. This may lead to a situation in which some students and teachers would like to, and may in fact, extend their well-established relationship beyond school setting. Extending their communication to OSNs may promote, in return, their relationship within the school setting.

Apparently, teachers who want to communicate with their students via OSNs are younger, less

experienced in teaching, and more experienced with social media altogether. They are also more supportive of using OSNs for learning and disagree more with a banning policy of OSNs for teacher–student communication. As for students, those who would like to be connected with their teachers are older, and have a wide range of OSN connections. They also believe more than their younger peers in using OSNs for learning, and disagree more with a banning policy of teacher–student communication using OSNs.

Broadening communication facilitates a notion of closeness and trust between them. This may in turn create a sense of intimacy that allows students to be sincere and open with their teachers. Therefore, this communication may have an impact on students' well-being altogether. Additionally, this communication may develop the students' future communication skills. Indeed, students perceive several benefits of communicating with their teachers via OSNs. These include the availability of teachers, with digital platforms serving as mediators in instances in which face-to-face communication may be awkward for students. OSNs also allow separation between private and school-related topics by utilizing different communication channels.

OSNs present possibilities of greater accessibility of students to teachers and vice versa. This could be the reason that teachers are also generally interested in broadening communication with their students and in using OSNs for learning purposes, in addition to their usage for mere communication; the ramifications may include improvement of teaching itself, dependent on teachers' professional development and learning regarding best practices of OSNs, as well as practice related to digital media literacies – these allowing in turn new types of communication. Teachers perceive OSN-based communication with students as serving multiple purposes: broadening of teaching and learning possibilities, psychological support, and deepening of the relationship altogether.

This connection is favored to a larger extent by the teachers, who see OSNs as a convenient means of conveying practical messages, based on mutual needs. Hence, the benefits of

communicating via OSN (e.g., broadcasting, multimedia, notifications, etc.) facilitate their use. The number of teachers that report they would like to be connected to students is twice as much as those who are connected *de facto*, and the former tend to perceive teacher–student OSN-based communication in a more romanticized manner than manifested in practice (Forkosh-Baruch and Hershkovitz 2017).

Naturally, communication between teachers and students using OSNs raise some debate and even controversies. Even the very term used in many OSNs to describe users that are connected to each other – “friends” – may challenge traditional student–teacher hierarchy, since traditionally teachers’ role allows them some power over their students, even when close relationship between the two are developed. Issues of controversy may be related to issues of privacy and disclosure of information. It seems that conflictual experiences in real life are translated to Facebook communication, and vice versa. Hence, it is understandable that teachers prefer having a professional profile for communicating with students in order to separate between their professional and personal spaces. Also, both teachers and students handle communication that is considered personal using private communication channels, such as messengers.

Both teachers and students understand the negative aspects of communication using OSN, including issues such as: invasion of privacy, excessive information (these two being most prominent claims), undermining teacher authority and respect, exposure to inappropriate or offensive student behavior, blurring of boundaries, inequity in opportunities for communication, poor or insufficient ICT literacy, improper behavior of both parties, and addressing identity issues. Students perceive negative aspects, such as overload and excessive noise caused by lack of focus and ill decision-making regarding importance of issues within the communication. Altogether, both teachers and students face the need to cope with an educational paradigm shift, in which both populations cope with changes in their roles; this is especially difficult for teachers, whose traditional role is changing rapidly within a

technology-saturated setting. While students have deep understanding of social media – teachers’ media literacy is altogether challenging and requires acquisition of skills and competencies. This literacy is a prerequisite for adequate teacher–student communication using OSNs, if a teacher chooses to do so.

Despite the intriguing challenges, and despite regulators’ attempts to limit teacher–student OSN-based communication, teachers tend to disagree with a banning policy. Surprisingly, students tend to agree with such a policy.

Conclusions

When addressing the topic of OSNs in education, there is a need to refer to the role of both teachers and students. Since the schooling system is hierarchic in nature, while communication on OSNs is flat and equal in nature, there seems to be built-in tension in this channel of communication. The possibilities, as well as the pitfalls, of utilizing OSNs for communication between teachers and students are enormous; in both cases, consequences may be life-changing. Therefore, this should not be referred to lightly, but rather studied in depth and comprehensively.

The psychological aspect of flattening the communications between students and teachers in terms of hierarchy, but enriching the interaction by broadening the communication beyond the physical arena, to the virtual spheres, may be beneficial to both students and teachers. They may utilize these new possibilities and broaden their relationship with each other. The drawbacks may include, first and foremost, invasion of privacy. Extending teacher–student communication beyond the classroom may impact mostly teachers, who may experience excessive effort in terms of separating between their personal and professional online identities. This requires support for teachers who are willing to dive into this position. Hence, these teachers should be digitally literate, in order to wisely use the new possibilities that OSNs enable for communicating with their students. This is quite complicated for teachers, some born prior to the OSN-era. However,

students, who are typically more digitally literate compared to their teachers may also not be using OSNs wisely, unaware of the consequences of some of their actions. Therefore, while opening new possibilities, communication via OSNs also carries some impediments.

Implications

The implications for promoting teacher–student communication using OSNs are twofold, including aspects of teacher training and their professional development and aspects related to policy.

Implications for Teacher Training and Professional Development

Teacher training is key to their professional development in the field of digital media, since most teachers are unaware of both technological and social-ethical aspects of using OSNs. Hence, there is a need to encourage teachers to develop their ICT literacy, including skills and competencies, in order to use OSNs wisely. This may be achieved by formal on-the-job training as part of teachers' professional development, or by practical usage of OSNs and monitoring and support by mentors. These mentors can be digitally literate teachers; all teachers could bring their experience regarding controversial situations into these programs. This will allow teachers to make informed decisions: to achieve proficiency as SNS users, to utilize OSNs for better communicating and learning, and to handle ethical aspects wisely, e.g., privacy issues and data usage. This training process should begin in pre-service teacher training, before teachers enter the education system, so teachers may avoid the pitfalls of blurred boundaries. Finally, teachers should realize the differences between private and public channels of communications and wisely conduct their communication accordingly, in a way that best fits their educational agenda. This will allow teachers to further gain their students' respect and trust.

Implications for Policy

Policy can promote or hinder teacher–student relationship, since policymakers are those who

set the educational agenda, whether national or local. Therefore, policy must not be taken lightly, and decisions should be established after studying evidence-based research conclusions.

By setting up policies that limit teacher–student OSN-based communication, policymakers convey a notion according to which teachers are not to be trusted and should not be given an opportunity to act upon their educational beliefs. The new media-saturated era conveys an opportunity to implement a more liberal policy, enabling teachers to practice their profession based on personal beliefs regarding the nature of education and the nature of teacher–student relationship.

Policymakers should trust teachers with decision-making regarding their relationship with their students – just as they are trusted with teaching them. Hence, comprehensive banning of OSN-based communication is potentially damaging to the education system at large, and to teachers' and students' well-being. Furthermore, a policy of “one size fits all” goes against personalization of learning, which has always been the pillar of education; therefore, policy should reflect a pluralistic view of OSN implementation in education.

Introduction

My understanding of this encyclopedia is that it is likely to have a fairly broad audience including researchers, teachers, other educators, and anyone interested in computing education. So the entries need to try to capture the current thinking, including issues, challenges, controversies, what is known, and what is not known. They need to draw on the literature, but they are not systematic literature reviews or even full literature reviews rather they are written by experts drawing on their expertise and citing key references.

This entry “Teaching About Computing” describes the role of informatics systems in teaching about computing and is structured into two main sections: (1) [Application of Informatics Systems](#) and (2) [Comprehension of Informatics Systems](#). “Application of Informatics Systems” is the most underestimated part of teaching about computing. Therefore a discussion of the “[Cognitive Dimension of System Application](#)” as well as the “[Non-cognitive Dimension of System Application](#)” will be presented.

The entry teaching about computing should work as an overview and is therefore related with more specific entries of this encyclopedia, e.g., “► [Competency Models in Computing Education](#),” “► [Curricula in Computer Science](#),” “► [Value of Teaching Computer Science](#),” and “► [Computational Thinking](#).”

The learning environments should be designed to support application, comprehension, and

development of informatics systems. Our research studies have shown that there is an imbalanced number of lessons. This means that we spend much more learning time on development of informatics systems and too little on application and comprehension of such systems. The roots of this error lie in the underestimation of the necessary competencies for application and comprehension. The informaticians are not blameless on this problem, because they claimed for a long period that informatics systems would be easily and intuitively applicable in the near future. The worldwide community of users could observe the failure of this assumption. In contrary, informatics systems become more and more sophisticated, and small errors may lead to difficult circumstances in our real-life situations, e.g., strangers capture your computer for illegal business and you as an individual have to satisfy the cheated customers.

Therefore, we developed appropriate learning environments for application and comprehension of informatics systems, which delivered the evidence for successful learning of different kinds of cognitive models of informatics, e.g., von Neumann architecture, and models of layers (multilevel computer). After this experience, the next task was to establish a learning environment that could be easily integrated into a curriculum over the period of four half-year courses. The

international discourse with expert teachers culminated in the following structure: A, von Neumann architecture as course 11.2 (this means, the students are members of the 11th grade; students are approximately 17 years old); B, models of layers as course 12.1; and C, design patterns as course 12.2. After 12.2 the A-level examination takes place.

Application of Informatics Systems

According to their definition, competencies encompass both cognitive and non-cognitive skills and abilities. The application of the empirical method Critical Incident Technique and qualitative content analysis (Mayring 2003) established competence categories with respect to a scenario on application of informatics systems. A typical scenario is “Literature research with online catalogue versus search engine.” This scenario and its questions will be introduced to the interviewees as follows (see Fig. 1).

A further important scenario on system application is the following scenario: “You just installed the newest version of your favorite database system. There are lots of new functions hidden beneath an astonishingly changed graphical user interface.” This scenario has similar questions (see above).

Scenario: After reading a scientific article, you need more information in this area. To do so, you are using an online catalogue of a library and a web search engine. In case of the search engine, one query gives no results, a second one more than 3 million.

Question 1: What do you expect of such an online catalogue or a search engine?

Question 2: How do you get information with both systems?

Question 3: That cognitive skills are required for the application of both systems?

Question 3.1: That informatics views are important for this task?

Question 3.2: That complexity would you assign to this task?

Question 4: That attitudes or social-communicative and cooperative skills are necessary to accomplish this?

Question 5: That strategy would pupils apply to solve this problem?

Question 6: That obstacles would novices have to cope with?

Cognitive Dimension of System Application

All interviews were interpreted through qualitative content analysis. The first results of the qualitative content analysis have to be structured according to the dimensions of a competence model. Relations between the competence categories and meaning units in the interview have to be found and described (matching). For this we use the following expressions: answer plus competence category followed by the original statement of the expert (if necessary shortened).

As expected we found new subcategories for the competence category “System application.” With the following answers, the new subcategories are proved exemplarily:

- Answer “Use of media to foster system application and system comprehension”: “I expect there are a tutorial and a collection of good examples available. If the only resource to foster system application and system comprehension would be the manual (in general with thousands of pages) then we face a huge problem. Beginners will fail and other persons, that are more experienced, will waste a lot of time.”
- Answer “Structuring of application field”: “In general, all these themes are hierarchically structured. This means, we found the universal informatics concept hierarchical structuring in the application field.”
- Answer “Selection of systems”: “I choose the informatics system as a tool that offers the best relation between benefit and costs.”
- Answer “Transfer to new application fields”: “Abstraction is one of the fundamental ideas of informatics that is transferable to new application fields.”

For the competence subcategory “Selection of systems,” the experts stress for the comparison of the systems the need of appropriate selection criteria, and for “Structuring of application field,” they recommend two strategies, top-down design and stepwise refinement that are usually used together. The qualitative content analysis leads to “System control,” “Design of input

data,” “Evaluation of output data,” and “Selection of appropriate storage” for the competence subcategory “Paradigm of Information Processing (Extern).” The following answers are examples for these new sub subcategories:

- Answers “Design of input data”: “Key words have to be distinctive for one application field.” “You have to formulate precise queries.” “Complex queries have to be developed.”
- Answers “Interpretation and evaluation of output data”: “I need a vision of what I am looking for to evaluate the output documents.” “There is a difference between the results in an online catalogue of a library and the results given by a search engine. In the case of an online catalogue, a quality assurance process exists.”
- Answers “System control: extern”: All experts describe strategies to optimize the search process: “For the work with the online catalogue, you need experience with powerful key words.” “You should compare the traditional heuristic of a search with the web-based facilities to reduce the search space.” “In special cases you need also the strategy to extend the terms of the search.”
- Answer “System control: intern”: “If I want my web site to be listed as one of the first results with respect to a certain query, I have to use relevant key words as metadata of the web site.”

The following task could help the learners to develop the skills necessary to apply informatics systems (see Fig. 2).

The learners have to decide for each statement if it is true or false. We as teachers evaluate the decisions of the learners. If the decisions are correct, then the learner shows the following competencies:

1. The learner is able to recognize fundamental ideas and concepts of informatics.
2. The learner is able to abstract from the given example to the appropriate model behind the example.
3. The learner has the ability to analyze the unknown informatics system with the help of

Task: Your parents want to publish their best recipes in an online cookbook. They want to demonstrate the preparation of the food through videos. Your parents also have purchased a new software for editing the videos. Unfortunately, they do not know the software very well because they previously used an other program, which was especially designed for beginners. But they know that the new software uses the same Open-Source components to de- and encode videos as the old software. According to this, which of the following statements are true?.

Statement 1: Both of the programs own the option "Distort Video" that can be found under the menu point „Effects“.

Statement 2: Both of the programs can import audio files in different formats.

Statement 3: Both of the programs can import videos in the same format for editing.

Statement 4: Both of the programs can enhance the videos with effects.

Statement 5: Both of the programs support different view modes for windows.

Statement 6: Both of the programs can export videos in the same resolution.

Statement 7: Both of the programs are suitable for beginners.

Teaching About Computing, Fig. 2 Task on application of informatics systems

- such fundamental (mostly abstract) models of informatics.
4. The learner develops goal-driven and efficient strategies for the application of the given or selected informatics system.

Non-cognitive Dimension of System Application

In the competence dimension “Non-cognitive skills,” the qualitative content analysis lead to “Target orientation,” “Demystification,” and “Self-determined acting” for the competence subcategory “Expectations for informatics literacy and professional practice.” The following answers are examples for these new subcategories:

- Answer “Target orientation”: “I need a certain target orientation to formulate my query as precise as possible.”
- Answer “Demystification”: “Pupils need criteria to evaluate sources; otherwise they take the first matching result for truth.”
- Answer “Self-determined acting”: “If the first result is not helpful, you have to refine and modify your query again and again.” “We have to avoid being helpless in front of such system.”

Teaching About Computing, Table 1 Selected competencies of system application

Cognitive dimension	Non-cognitive dimension
(1) Use of media to foster system application	(1) Target orientation
(2) Structuring of application field	(2) Demystification
(3) Selection of systems	(3) Self-determined acting
(4) System exploration	(4) Cooperation and teamwork
(5) Transfer to new application fields	(5) Change of perspectives and roles (user, developer)
(6) Design of input data	(6) Openness to new ideas and new requirements
(7) Interpretation and evaluation of output data	(7) Learning motivation

But we found not only new non-cognitive sub subcategories. As expected any non-cognitive subcategories were proved (see Table 1). The following selected responses of interviewees are examples for these:

- Answer “Cooperation and teamwork”: “The plenary discussion would be the best opportunity to evaluate the draft design of a data model and to improve it stepwise in teamwork.”
- Answer “Change of perspectives and roles (user, developer)”: “Pupils have to play different roles with different rights (access to read,

Scenario: You are asked by a colleague to test his software, that was developed to solve configuration problems, e.g., to set up a new car or a new computer.

Question 1: What is your strategy of testing to solve this problem? That aspects do you have to bear in mind?

Question 2: That cognitive skills are required for such a software exploration?

Question 2.1: That informatics views are important for this task?

Question 2.2: That complexity would you assign to this task?

Question 3: That attitudes or social-communicative and cooperative skills are necessary to accomplish this?

Question 4: That differences of competence levels would you expect between novices and experts?

Question 5: How can you as a tester be supported by this task?

Question 6: Could you imagine a potential pupil's procedure to solve this problem?

Question 7: That obstacles would pupils have to cope with?

Teaching About Computing, Fig. 3 Scenario on testing of unknown software and its questions (Schubert and Stechert 2010)

access to write, access to delete) to learn more about the consequences of their decisions and actions.”

Answer “Openness to new ideas and new requirements”: “We have to provoke and to satisfy a huge curiosity for the exploration of informatics systems. On the other hand pupils need to have a high level of frustration tolerance.”

Answer “Learning motivation”: “We may use the attraction of similar applications like ‘Facebook’ on networked communities to stimulate the learning motivation of database application.” “Many pupils like to start a competition with a small problem solution that is incomplete, and the winner of the competition has to present the best improvement of the solution.”

This research phase has shown that the cognitive and non-cognitive dimensions of system application are mostly underestimated. We found very important subcategories, i.e., for the cognitive dimensions (Use of media to foster system application, Structuring of application field, Selection of systems, Transfer to new application fields) and the non-cognitive dimension (Target orientation, Demystification, Self-determined acting).

Comprehension of Informatics Systems

The application of the empirical method Critical Incident Technique and qualitative content analysis established competence categories with respect to a scenario on system comprehension. In Fig. 3 such an interview scenario is presented:

Table 2 shows the cognitive competence categories and non-cognitive skills that were mentioned by the experts with respect to system comprehension.

Change of Views

The competence dimension “Change of views” is very important. For problem-solving, the selection of the most appropriate informatics strategy is crucial for success. Therefore, theoretical foundations and practical tools have to be considered. Denning defines different views on informatics, i.e., “The five windows of computing mechanics” (Denning, 2003, p. 17). Therefore, a change of views is recommended between different solution strategies of problem-solving. Several experts mentioned that informatics is more than programming and should not be reduced to it. So, we have to offer more than the programming

Teaching About Computing, Table 2 Selected competencies of system comprehension

Cognitive dimension	Non-cognitive dimension
(1) System exploration	(1) Attitudes, e.g., expectations for informatics literacy and professional practice
(2) External view, e.g., observation of systems' behavior	(2) Social-communicative skills, e.g., change of perspectives and roles (user, developer)
(3) Internal view, e.g., paradigm of information processing	(3) Motivational and volitional skills
(4) Change of views	
(5) Scalability	

perspective. Moreover, the experts' statements lead us to the assumption that this competence dimension is incomplete if only a static sequence of "External view" and "Internal view" with their facets is considered. Thus, we insert a new category, "Change of views." Also the competence category "External view" needs refinement, but only with one new subcategory, "Paradigm of information processing (extern)," including input-output relations and state diagrams to explain and visualize the system's behavior.

Strongly connected to the selection of the most appropriate problem-solving strategy and, therefore, with the newly introduced competence category "Change of views" is the problem of scalability. It characterizes the phenomenon that an informatics strategy can be optimal to solve a given problem within a small informatics system, but the same strategy can be unrewarding given the same problem in a larger context. For example, in the field of informatics, we distinguish between "programming-in-the-small" and "programming-in-the-large." Thus, the scalability of problem-solving strategies is related to the complexity of a problem or an informatics system. The criterion scalability can be used to decide that solution (system, algorithm, process) should be applied to different problem sets. There are nearly no publications for the influence of scalability on system comprehension. Furthermore, scalability is an

evaluation criterion for the range of application of a given informatics system or tool. The experts' statements lead us to the conclusion that it is necessary to put scalability into the competence model as new competence category "Scalability," with strong connection to the other complexity factors.

Exploration of Informatics Systems

The following scenario "Usability engineering" belongs to the set of scenarios that should deliver research results on system comprehension: "You get software for the management of personal collections, e.g., books or DVDs. The software should be used on mobile phones. It is in your responsibility to test the usability." This scenario has questions similar to the scenario in Fig. 3. Here we found "System exploration" as an important new subcategory for the competence model. The experts answered: "When I want to choose free software, then I download and explore it."

Firstly, we insert this new competence facet into "System comprehension," but for a newly proved competence category or competence subcategory, there is more than one opportunity to add it to the competence model. All competence facets that are helpful for system application bring advantages for system comprehension, and the facets from there support system development in turn. So, we face the problem of deciding where the best place for each competence category and subcategory is in our model. In case of different possibilities, we recommend to insert it in each competence area. As an example "System exploration" could have been assigned to "System application" or "System comprehension." The majority of experts' statements in the scenarios indicate an assignment to "System application" and emphasize how important system exploration is in this competence area:

- Answer: "In this case, we have to use software exploration."
- Answer: "Pupils should work playfully with a database system to change from external to internal views."

The conclusion of these experts' statements is to introduce the new item as "System exploration" to "System application."

Summarizing, "System exploration," "Change of view," and "Scalability" are the most important results of empirical evaluation on competencies of system comprehension, because we have shown a close relation between application and informatics system comprehension.

The following task could help the learners to develop the skills necessary to comprehend informatics systems (see Fig. 4).

In Part A the learners have to allot the 1–3 errors to one of the stated meanings. We as teachers evaluate the decisions of the learners.

If the decisions are correct, then the learner shows the following competencies:

- 1. The learner is able to identify the errors produced by the informatics system.
- 2. The learner is able to distinguish between these errors.
- 3. The learner is able to evaluate such errors correctly.
- 4. The learner improves his tests of informatics system and avoids the same errors.

In Part B the learners have to decide for each statement if it is true or false. We as teachers evaluate the decisions of the learners. If the

Task: During his free time a friend of you has developed software, which can be used to calculate the volume of a cube. Thereby the volume of the cube is defined through the side length of the cube. Your friend asked you to systematically test the software. During the input of the side length it could happen, that you encounter the following errors:

- 1. Error: incompatible types - found "double" but expected "int"
- 2. Error: cannot find symbol - variable "quantity"
- 3. Error: stack overflow at line 201

Part A: What do the errors stand for? Allot the 1 -3 errors to one of the stated meanings. Each number only appears once.

No.	Statement
	You entered a decimal number instead of an integral number.
	You entered a string instead of the side number.
	You entered a symbol instead of a variable.
	The source code "stackoverflow" in line 201 is syntactically not correct.
	The number was accidentally entered twice (double) instead of once.
	The data volumes become too big for the reserved memory, because of an error in the program.
	The symbol for the variable "quantity" was not inserted in the source code.
	The variable "quantity" was not declared.
	You entered an integral number instead of a decimal number.

Part B: The values 0, 3, 5 and -3.5 have been tested. The program does not show any errors. Now, you enter the value 3000053. Which error tests this value, which has not been tested before?

- 1. The value tests if the combinations of the tested values lead to an error-free program start.
- 2. The value tests if integer values lead to an error-free program start.
- 3. The value tests if there are other incorrect parts of the program, which are used with big values.

Teaching About Computing, Fig. 4 Task on comprehension of informatics systems

decisions are correct, then the learner shows the following competencies:

1. The learner is able to apply well-known strategies of tests.
2. The learner is able to explain the advantages and disadvantages of different strategies of tests.

Conclusion

Application and comprehension of informatics systems are essential in teaching about computing. We could support teachers by their work in creating competency-based tasks for their students. Such tasks need to be connected to an empirically refined competence model. The examples of expert interviews given in this entry are only the beginning of a comprehensive research field. We face the issue to establish competence models for all parts in teaching about computing.

Although the deployment of the qualitative content analysis took place adhering to comprehensible, methodical rules and principles, it is inevitable that qualitative analyses are interpretative processes which might restrict the objectivity, reliability, and validity of the described analyses. We recommend the application of the following research methodology (Margaritis et al. 2015):

- The evaluation of the content validity of the model that can be accomplished by an expert rating. To make sure that we are not missing some important items by the used scenarios, we have to combine the interviews with a representativeness rating through the experts. This means, the different informatics experts have to rate the extracted competence descriptions concerning their relevance, difficulty, representativeness, and degree of differentiation.
- After this rating, we can develop instruments to measure (e.g., test items for the learning results, observation of learner-centered approaches) the different categories of the competence model in classroom practice.

- Based on the results of the measurement, we can focus on improving learning environments in informatics secondary education.

As described our project had the following intentions. First, we wanted to investigate which competencies are required to learn computer science in schools. Second, we aimed to design an instrument to measure some of these competencies. Third, this instrument had to be validated. Regarding these goals, we were quite successful. We found a convincing category system that provided a suitable structure for a competency structure model, which was applied successfully to other learning contexts already (Neugebauer et al. 2015).

Teaching and Learning Computational Thinking and Coding Skills

Jari Multisilta¹ and Pauliina Tuomi²

¹Satakunta University of Applied Sciences, Pori, Finland

²Tampere University, Tampere, Finland

Introduction

Digitalization is one of the most promising ways to increase productivity in society. In addition, it is widely accepted that digitalization will renew the economy, also substantially affecting the transformation of work life by creating new jobs resulting from innovation (Brynjolfsson and McAfee 2011; Mokyr et al. 2015). The educational system is also influenced by digitalization in at least two ways. First, the educational system is a platform that has been digitalized similar to the other sectors of society, meaning new learning methods, tools, and communication between schools and homes. Second, a digitalized education system is intended to build digitally literate citizens who have gained the skills to be active members of the digital society, participants in its economic, as well as in other societal, processes. Digitalization has influenced almost all work tasks and has created completely new jobs requiring competence to utilize computers and other digital devices (Frey and Osborne 2013; Niemi et al. 2014; Michaels et al. 2014; Bessen 2015). The implementation of digital services requires problem solving, design skills, logical thinking, understanding of how computers and networks operate, and programming competence. These abilities are useful for learning computer programming and computational thinking. This skill set can also be

considered coding skills. The term coding skills has various definitions ranging from narrow computer programming abilities to a general idea of computational thinking, a competence of formulating a problem and expressing its solutions in a way that an operator can effectively carry them out (Tuomi et al. 2017).

According to Denning (2009), computational thinking can be defined as the ability to interpret the world as algorithmically controlled conversions of inputs to outputs. In other words, computational thinking involves learning to think about, represent, and solve problems that require a combination of human cognitive power and computing capacity (Kafai and Burke 2013).

Computational thinking and coding skills are required to understand how our society and services work, and they will be increasingly required in future job descriptions. They can be seen as a set of skills every citizen should master. The Internet industry and the Internet of Things will expand the number of connected devices; in addition, different sensor-based solutions will produce large user, device, and environmental datasets. For analyzing these data, logical thinking, problem-solving, and coding skills are required.

Digital competence is fast becoming the most desirable asset in today's labor market, and 90% of all European jobs require computer skills at least on some level. Despite this, there is a growing gap between the number of European ICT vacancies and the number of skilled workers available to fill them. According to Balanskat and Engelhardt (2015), by 2020, Europe may experience a shortage of more than 800,000 professionals skilled in computing and informatics.

Computer programming has been taught at universities since the 1960s. However, only recently have educational systems started to understand the meaning of coding skills and computational thinking in general. The current job descriptions that include coding skills are for artists, developers, and producers. It is widely believed that learning coding skills leads to a more creative society. People are consuming more software and media products than ever, but only a tiny percentage of the population can

modify, customize, or create their own digital media and products.

The majority does not recognize the patterns behind digital products, which is the main reason that coding skills should be taught at every school. According to Microsoft, two-thirds of ICT jobs exist in non-ICT industries (from the manufacturing and automotive sectors to healthcare and retail), and the transferable, creative skills learned through coding are applicable across a range of professions. In Europe's schools, computer science is more often seen as marginal, instead of being considered a foundational subject, like languages, mathematics, or science. Fewer than 15% of European students have access in school to the kind of high-level ICT teaching they need to develop collaboration, self-regulation, and critical thinking.

Numerous studies have pinpointed that students experience many difficulties in learning to program (Webber and Possamai 2009; Koscianski and Bini 2009; Lahtinen et al. 2005). Educators agree, however, that students need to learn a programming way of thinking, which is more than just knowing the syntax and semantics of a language (Holvikivi 2010). The most important distinction to emphasize is the difference between teaching programming as a subject and understanding coding skills as part of a general set of twenty-first-century skills.

Learning Theories for Computational Thinking and Coding Skills

No single learning theory describes how coding skills and computational thinking should be learned. In this chapter, two theories that have been shown to be useful are presented.

To extract young people's full potential, they need to understand how new technologies work. From the theoretical point of view, inquiry learning (IL) can be used to describe the learning process where students learn through internal curiosity and doing (Sharples et al. 2013). Panjwani (2015) stated that inquiry-based science education (IBSE) can increase pupils' interest in science while also motivating teachers (Panjwani

2015). According to various reports and studies, school science teaching must be more engaging through applying inquiry-based and problem-solving methods to meet the interests of young people. Inquiry-based learning is a method, which enables learners to discover different kinds of subject matter knowledge through inquiry experience. It starts by posing questions, problems, or scenarios – rather than simply presenting established facts or portraying a smooth path to knowledge. In this way, inquiry learning imitates how a scientist works.

Another theory describing learning in technological environments is Kolb's experiential learning theory (ELT). In ELT, learning is described as a circle, where concrete experience, reflective observation, abstract conceptualization, and active experimentation are phases of learning that follow each other. Through the process of moving from concrete experience to active experimentation, the learner experiences an event (such as the first iteration of programming code), reflects on the results (the program produces a certain output with a certain input), creates an abstract concept, designs a new version of the learning activity, and starts a new cycle by doing another experiment (such as running the program code again). The cycle can be repeated as many times as necessary. Kolb's theory supports students in applying their knowledge and conceptual understanding to real-world problems.

Inquiry learning and experiential learning theory aim to teach students the competencies they need for real-world success. The two theories support the idea of seeing the school and its surroundings as a holistic network of learning environments, focusing on children who today are learning the twenty-first-century skills they need to be successful in work and play in 2030 (Korhonen et al. 2014).

Coding Skills as a Part of Maker Culture

Coding skills are often related to the idea of maker culture activity. Maker culture is a contemporary culture or subculture representing a technology-based extension of DIY culture. Typical interests

include engineering-oriented activity (such as electronics, robotics, 3D printing, and the use of computer numerical control (CNC) tools), as well as traditional activities (such as metalworking, woodworking, and traditional arts and crafts). In maker culture, there is a strong focus on using and learning practical skills and applying them to create something personal. Simple examples of maker culture include the trend of customizing your mobile device (by adding stickers or small shiny stones on the phone cover) or customizing your clothes.

Maker culture focuses on using and learning practical skills and then applying them creatively to different situations. Maker culture draws upon a more participatory approach than traditional learning, encouraging learners to collaboratively engage with others as they learn through the creation of new items (Sharples et al. 2013). Maker culture then emphasizes informal, networked, peer-led, and shared learning motivated by fun and self-fulfillment (Niemeyer and Gerber 2015).

Three Approaches for Learning Coding Skills

As a part of twenty-first-century skills, future schools should teach the wide variety of coding skills in the best and most effective ways. In a previous study, different approaches and methods of promoting coding skills in formal and informal settings (i.e., in school and outside school environments) were classified. The three larger approaches for learning computational thinking and coding skills take place in:

1. Formal settings (schools within the curriculum)
2. Nonformal settings (online and after-school clubs)
3. Informal events (hackathons, jams, etc.; Tuomi et al. 2017).

In formal settings, the ways coding skills are approached in schools within the curriculum vary greatly across countries and cultures. In non-formal settings, different coding skill activities

take place in after-school clubs. In these club activities, children can achieve hands-on experience in coding and creativity for example, through creating devices using cheap computing hardware, such as the Raspberry Pi. A common theme of after-school clubs in relation to learning coding skills is robotics. Many studies indicate that educational robot activities have a positive impact on the development of students' critical thinking, problem-solving, and metacognitive skills (Atmatzidou and Demetriadis 2014, 2016) and on the learning of a programming language (Alimisis 2009; Nourbakhsh et al. 2005). Other studies demonstrate that educational robot activities promote an enjoyable mode of learning, in addition to advancing students' motivation, collaboration, self-confidence, and creativity (Miller et al. 2008; Eguchi 2010; Khanlari 2013). Diverse informal coding events (hackathons, jams, etc.) are taking place. Usually, they can easily be combined with school activities, but they are also accessible for individuals, outside school participation. Many coding events take place throughout Europe, such as the Hour of Code, the European Union (EU) Code Week, and the Year of Code. In many cases, schools utilize coding events and materials created by nonprofit organizations, governments, or companies. Coding skills are promoted through companies as a part of their business or corporate social responsibility programs, through organizations such as science centers, through charities, and through different themes, such as gender, robotics, and hackerfests. There are also several options to learn coding worldwide through virtual academies, such as the Microsoft Virtual Academy or Codecademy, at the individual level.

In the last few years, the diversity of job descriptions has also supported women to find the industry a more welcoming place to work. Despite this development, there are still few female programmers, coders, developers, and programming coordinators (Ensmenger 2012; Ilomäki 2011). Ensmenger (2012) studied the process of how and why the field has become predominantly male. The profound effect of the stereotypes embedded in advertisements and hiring practices on masculinizing this profession can

also shed light on what can be done to reverse the trend, making programming and other computer professions more open to women (Ensmenger 2012; Abbate 2012).

It is important, however, to be reminded about women's forgotten contributions to the computing field. According to Fritz (1996), the very first programmers were the women, for example, operated the Electronic Numerical Integrator and Computer (ENIAC; the world's first electronic computer) in the United States of America (USA) in the 1940s. In addition, the Bletchley Park codebreaking operation during World War II relied heavily on women. The recent lack of women in tech has been widely acknowledged (Ensmenger 2012; Ashcraft et al. 2012). However, since the situation has become more visible, it has started a movement to encourage women to engage with technology through different events and tech-oriented societies. Today, there are more resources than ever to help women break into the technology industry (Tuomi et al. 2017).

Coding Skills in Finnish Curricula

Teaching of ICT was introduced to the Finnish curriculum in the 1980s, starting first in high schools in 1982. Computer skills were seen as important, but the number of computers in Finnish schools was not adequate to reach all students. However, many computer activities were carried out in different computer clubs after school. Computer club activity was especially important in experimental schools in the early 1980s, although some computer courses had been available at a limited level in the late 1960s and 1970s (Saarikoski 2011). The teaching of computer skills in schools was clearly linked to the rise of the Finnish home computer market in 1983 and 1984. Computer hobbyists played a major part in the domestication of ICT skills. User groups, clubs, and subcultures emerged rapidly all over the country during the 1980s. The media image of home computers was also very positive, almost overly optimistic, at the time (Saarikoski and Reunanen 2014). During the 1980s, official reports and curriculum projects clearly

emphasized that youngsters should learn the basics of this new literacy. Predominantly, this meant that schools were obligated to purchase computers and other hardware. Computer training was also arranged for teachers. Computer education faced a lot of practical problems; for example, software support was weak, and teacher training was hastily arranged. In secondary schools, the actual subject of ICT was added to the curriculum in 1987 and 1988, when it became one of the optional subjects. In 1994, ICT started to lose its place as an individual subject. ICT skills became seen as a larger part of other subjects, meaning ICT could be approached through several subjects, and thus, it became more cross-curricula (Sinko and Lehtinen 1999; Vahtivuori-Hänninen and Kynäslähti 2012).

From the maker culture point of view, making things with your own hands has always been embraced in Finnish schools. Crafts as a subject in schools and in the curriculum have existed for decades. However, changes in society and in the labor market have affected the use of materials and techniques in the teaching of crafts (Kansanen 2004; Pöllänen 2009). In the 1970s and 1980s, crafts subjects included textile and technical approaches. Especially for boys, the subject of electronics paved the way for different handcraft activities based on the first computers that arrived in schools. Students tinkered with the actual hardware from scratch to make it work (Tuomi et al. 2017). The tinkering and assembling of hardware represented similar handcraft ideology that can be seen today in robotics, 3D printing, and such. Maker culture and crafts as a school subject was and is a familiar phenomenon in Finnish schools. It seems the schools are now experiencing the second wave that as before, acknowledges that coding or programming is much more than just typing the code, and can include operations that require a hands-on approach (Tuomi et al. 2017).

The new national core curriculum for primary education in Finland (from 2016 onward) states that programming, or coding, will be part of all education. In Finland, most lessons in grades 1–6 are taught by each class's own teacher; thus, classroom teachers must be able to understand and meaningfully use coding as a teaching and

learning tool. The curriculum states, for example, that to get a good grade in mathematics, a sixth-grade student must be able to create simple programs using a visual programming environment such as Scratch (although others are available; Tuomi et al. 2017).

Several coding-based workshops and events have also been developed in Finland that offer individual training possibilities, outside school activities (clubs), and teacher training. Currently, teachers in Finland are implementing the new national core curricula and are looking for the best practices for teaching coding skills at all levels of primary education. There is an actual need for ongoing support, and teachers and the teacher union have requested more training in coding skills for in-service teachers. The change in the core curricula has also activated educational publishers to produce teaching and learning materials for coding skills (Tuomi et al. 2017). The new national core curriculum crystallizes the vision of education for the future and the expertise needed in Finnish society. The ongoing curriculum process is a key factor in developing the educational sector in Finland for twenty-first-century skills and competences (Niemi et al. 2014).

Case: Learning Coding Through Play

Computer programming or coding has been included in the Finnish National Core Curricula (FNCC) since 2016. It is not an independent subject, but it is integrated in other subjects. The FNCC defines several transversal skills that should be taught and learned in every subject. ICT competence is among these transversal competencies. The FNCC states: “The teaching and learning make use of the information and communication technology (ICT) skills the pupils have acquired during pre-primary education and outside of school. Play-based working methods are still important.”

The FNCC states that pupils should work with digital media and age-appropriate programming tasks. Key content areas related to the objectives of mathematics in grades 1 and 2 state that “the

pupils began familiarizing themselves with the basics of programming by formulating and testing step-by-step instructions.” This also supports the development of logical thinking and problem solving. An example of a classroom activity suitable for learning step-by-step instructions is an activity where pupils work in pairs (pupils A and B). Pupil A acts as the computer and pupil B as the computer program. The aim is to give specific instructions to pupil A so that he or she can perform a simple task just by following pupil B’s instructions. A simple case is moving an object (e.g., a pencil) on a table from one point to another point, for example, from the left side of the table to the right side. First, the teacher explains the aim of the classroom activity and then divides the pupils into pairs. The pupils decide their roles as the computer or the computer program. Pupil A, the computer, must have a pencil on her left side on the table. The computer program (pupil B) gives instructions, for example: “move your left hand over the pencil,” “grab the pencil with your left hand,” “move your left hand up,” “move your left hand to the right about 10 cm,” “move your left hand on the table,” and “release the pencil from your left hand.” First, the pupils learn that the instructions should be precise and descriptive. In addition, the instructions should be given in the right order. If a step is misunderstood or is missing, the task will fail. In the next phase, the activity could be modified so that the computer program does not see what the computer is doing. This makes it necessary for the computer program to plan the instructions beforehand, and it is not possible to correct the instructions in the middle of the task.

The pupils and the teacher could discuss the concepts or words the computer program uses as an instruction. For example, is it assumed that the computer understands every word the computer program says? The final phase could be that the pupils design a list of the instructions the computer understands and then try to do the task using the limited instruction set. In addition, the pupils could plan the task by themselves. It does not have to be the moving the pencil task, but it could be, for example, a drawing task. In this case, the computer has a piece of paper and a pencil, and

the task is to give orders to draw, for example, a house.

Games can also be used in learning computer programming. Several games specifically teach logical thinking, and some games teach programming as such. For example, a game called Foos is available for iOS and Android devices (www.thefoos.com). In the game, the player solves a set of puzzles in a world called Foosville. The game uses an icon-based graphical programming “language” that is used in solving the puzzles. The Foos web pages have materials for teachers so that they can develop their own lesson plans for the Foos game. Another game that teaches logical problem-solving is called Wuzzit Trouble, designed by Dr. Keith Devlin from Stanford University. Similar to the Foos game, Wuzzit Trouble has no written words, so it can be used in various countries and without any knowledge of English (or any other language). In the game, the player tries to open a lock in a cage and release a cute Wuzzit character from the cage. The lock can be opened by operating the gears, which the player can turn. Opening the lock requires a certain set of operations with the gears, so logical thinking is needed.

Case: Learning Coding with Visual Programming

In the FNCC, the aim for grades 3–6 is to try out computer programming in a graphics programming environment. The key content areas that computer programming contributes are related to the mathematics subject and to thinking skills and data processing skills.

Graphical programming environments are an easy way to start to learn programming. Several applications and web sites implement a graphical programming environment suitable for learning programming at school. One of the popular environments is Scratch, a free programming environment that can be used with a web browser. In Scratch, there is a stage on which the pupil can put graphical objects. Each object can have its own short program. The programs are presented as flowcharts, and the pupil can drag and drop

flowchart icons to the program. The icons are like puzzle pieces snapping together when they are in the correct place. The flowchart icons have text labels, so the pupil needs to understand written language.

Programming in a graphical environment is generally very easy. For example, the main character in Scratch is a cat, which can be programmed to move around the stage. The pupil can also easily add sounds. The first programming tasks in the Scratch environment could be to create digital animations and stories. In addition to programming, pupils can design their own objects to be put on the stage. Working in the Scratch environment integrates other subjects well, as designing objects could be art class work and creating the storyline could be something that is typically done in drama class.

Pupils can share their work in the Scratch environment with other users. This is also an important way to learn coding. Looking at how others have implemented something is actually a common way to learn programming in other programming languages. Many professional coders share their questions on Internet discussion sites (such as Stackoverflow) and get help from other professionals.

Although Scratch is an easy environment, it is quite powerful. For example, many great interesting games are implemented in Scratch.

In addition, the ScratchJr version of Scratch is available as an iPad or Android tablet app. ScratchJr is designed for younger pupils (preschool), and it does not require any reading skills. The flowchart icons do not have any text. In ScratchJr, pupils can also create stories and animations.

In graphical programming environments, pupils learn many core programming concepts. Variables, instructions, loops, *if-then* statements, functions, and objects are all present in graphical programming environments.

Case: Learning Coding with Robotics

A well-known robotics environment for kids is Lego Mindstorms EV3. It integrates Lego blocks,

sensors, and motors in a graphical programming environment where pupils can create moving robots that can do different tasks. In Finland, robotics has been an after-school activity for several years, but the FNCC 2014 brought robotics into school.

Lego Mindstorms EV3 includes making a robot using the available blocks and components. There are also simple robots that can be programmed without making the robot first. SPRK is a robot shaped like a ball, and it can be programmed with a graphical programming language by using a smartphone app. The smartphone is connected to the robot by a Bluetooth connection. The ball can be programmed to travel through a certain route, and the ball can detect its orientation, position, and collision to another object. In a classroom, the teacher can use these robots, for example, to create a competition for whose robot and program travels a certain route the fastest. The pupils would then create programs for the robot and then let the robots compete against each other.

In Finland, computer programming also integrates crafts in grades 3–6. In general, the key content areas in crafts include producing ideas, design, experimentation, production, application, documentation, and assessment. In the crafts subject, pupils experiment and design with a diverse range of materials, such as wood, metals, plastics, fabrics, and recycled materials. In addition, “they practise with functions produced the help of programming, such as robotics and automation” (Finnish National Board of Education 2016, Ch. 14.4.12).

Discussion

The Microsoft news center emphasizes that digital skills are life skills. However, the lack of programming and computer science in K–12 education is increasingly recognized as a serious lack in the national curricula of many countries (Guerra et al. 2012; Sengupta et al. 2013). According to Dagiene et al. (2014), many European countries have included informatics in their curricula since the 1970s, but many of these efforts have been dropped for various reasons. Therefore, many

students graduate from secondary school with quite a lot of experience of using computers and software, but little, if any, knowledge of the underlying principles (Dagiene et al. 2014).

The European Union has started to support the introduction of coding in schools. Learning to code teaches essential abilities, such as computational and abstract thinking, and it is just one of a wide range of digital competencies that could help Europe’s children enhance their creativity, flexibility, and problem-solving skills.

Teaching coding skills does not happen without the teacher. It is important that teachers are educated, guided, and supported at the practical level to meet the requirements of coding skills in the curriculum. Many countries are including twenty-first-century skills, computational thinking, and coding skills in the curriculum, but many countries lack, at the national level, official and adequate education and training for teachers for implementing coding-based activity in their school work. Gathering the different practices worldwide would promote the idea of lifelong learning and support the modernization of education and training systems, in particular through recognition and the dissemination of good practices. Maker culture has the potential to contribute to a more participatory approach and create new ways to learn technology-related topics. In addition, maker activities support learning Science, Technology, Engineering, and Mathematics (STEM) subjects. Through this, underachievement in the basic skills of mathematics could be addressed, and science and literacy introduced through more effective, innovative teaching methods.

There have been debates whether all children should learn coding skills in primary or secondary school, or if these skills should be taught only to those who aim to be programmers. Overall, computational thinking and coding skills should be basic skills for everyone who lives in the information society. Therefore, the capacities of future employees should be enhanced by introducing computational thinking skills in primary school. It is especially important to make sure that students meet the requirements of each school level and the transition points in education, such as

moving from elementary to high school and from high school to university.

To conclude, coding skills are one of the most intriguing challenges that schools, educational boards, administrations, and societies face. In this entry, ideas and examples for teaching and learning computational thinking and coding skills were provided. In addition, the importance of everyone learning coding skills in primary school was emphasized. Based on the current technological development, learning computational thinking and coding skills will be important building blocks for the school of the future.

Definition

A computer language may refer to any of a variety of languages used to express a set of detailed instructions to a computer so that it performs specific tasks.

Introduction

This section will discuss a variety of issues surrounding the use of computers in universities and throughout higher education. The initial entries focus on teaching university students how to write computer programs and solve problems using algorithms.

This entry introduces computer languages, defined above as any of a variety of languages used to express a set of detailed instructions to a computer so that it performs specific tasks. Such languages are based on specific syntactic and semantic rules used to define the meaning of the programming language constructs.

Programming Overview

Various programming paradigms have emerged over time. A programming paradigm is a collection of coherent, often ideologically or theoretically based abstractions that together mold the design process and ultimately determine a program's structure (Wampler and Clark 2010; Ambler et al. 1992).

The paradigm being followed influences the program development process. There are various approaches for developing programs, including the process-oriented approach and the object-oriented approach.

Process-Oriented Approach

When using the process-oriented approach, the problem being analyzed is considered from the aspect of what processes or procedures must be performed in order to convert the provided input into the desired output. When following this approach, each program specifies a list of instructions indicating how the program's purpose is accomplished. Developing a sequence of instructions for a computer to follow involves a certain process. The problem-solving phase involves analyzing the problem and devising a general solution called an algorithm. An algorithm is simply a step-by-step outline detailing how to solve a problem in a finite amount of time. After testing the algorithm to confirm that

it works correctly, it can be translated into a programming language.

As programs become more complex, understandability can be improved if each process is considered separately. This is done by dividing the program into functions or subprograms. Each subprogram should have a clearly defined purpose and a clearly defined interface to the other subprograms in the program. This subdivision of programs can be carried further by grouping related subprograms into modules, referred to as modular design. The "divide and conquer" approach is one of the cornerstones of structured programming. Structured programming, along with its familiar features such as modular design, has long been a reliable approach to program development.

Object-Oriented Approach

One of the primary shortcomings of traditional program development techniques is their inability to easily handle the complexity associated with today's larger programs. Object-oriented (OO) development techniques are better able to cope with this complexity by offering several improved features such as data hiding, encapsulation, and polymorphism that make large programs easier to maintain and modify.

OO designs are thought to more accurately model the real world. Instead of viewing the world as a set of processes, it views the world as a collection of entities that are characterized by certain behaviors. Furthermore, OO languages make it easier to create new data types to better represent real-world objects.

The fundamental idea behind OO languages is to combine both data and the functions that operate on that data into a single unit called an object. In order to conceptualize a programming problem, the programmer determines what parts of the problem can be most usefully represented as objects, and then all the data and functions connected with that object are combined in the class specification. An object's functions, referred to as methods, provide the only way to access its data. In order to determine the value of a data item in an object, one of the object's methods must be called to read the data item and return its value.

The data cannot be accessed directly. It is hidden and is safe from accidental alteration. Data and functions are said to be encapsulated into a single entity. Both data encapsulation and data hiding are key concepts in the object-oriented paradigm. Restricting changes to an object’s data to its member functions ensures that no other functions can alter that data and therefore simplifies writing, debugging, and maintaining the program.

Language History

Both programming languages and program development techniques emerged near the middle of the twentieth century. Von Neumann’s (1945) computer architecture led to very early programming languages, which were individual machine languages designed to control specific central processing units. UNIVAC’s C-10 language, developed in 1949, was the first computer language and made use of mnemonic instructions, like “a” for add and “b” for bring. It was not long before high-level programming languages with more natural syntax became available to simplify computer programming. By the late 1950’s, universities had discovered, and in many cases created, higher-level languages.

The Computer History Museum (<http://www.computerhistory.org/>) provides a visual timeline for the creation of early languages, which is summarized in Table 1.

FORTRAN, designed to ease the translation of mathematical formulas into code, was released in 1957. ALGOL, released in 1958 and updated in 1960, introduced recursion, indirect addressing, and character manipulation, among other features. Many universities adopted ALGOL for use in their computer programming courses because it provided a precise and useful way for expressing algorithms (Keet 2004). COBOL was developed in 1959, and 80% of the world’s daily business transactions still rely on COBOL (Beach 2014). Along with BASIC, these early higher-level imperative paradigm programming languages (Wilson and Clark 1993) used global variables, assignment statements, labeled commons, and goto statements to implement increasingly

Teaching Computer Languages in Universities, Table 1 Timeline of early language creation (from <http://www.computerhistory.org/timeline/software-languages/>)

Year	Development
1945	Zuse begins Plankalkül (plan calculus), the first algorithmic programming language
1948	Shannon identifies the bit as the fundamental unit of data and shows how to code data for transmission
1952	Hopper completes the A-0 compiler
1953	Backus creates Speedcode for the IBM 701
1957	IBM team led by Backus develops FORTRAN
1958	Algol 58, intended to be a universal language, released
1959	LISP created by McCarthy
1959	COBOL created by a team representing manufacturers and pentagon
1962	Iverson develops APL
1963	First edition of the ASCII standard published
1964	BASIC created at Dartmouth by Kurtz and Kemeny
1965	Simula written by Nygaard and Dahl
1969	UNIX developed at AT&T by Thompson and Ritchie
1970	Pascal programming language introduced by Wirth
1972	C programming language released by Thompson and Ritchie

complex programs. While these early languages had subroutines, lengthy programs often featured multiple goto statements that branched throughout the rest of the code. The resulting “spaghetti code” (Conway 1978) was difficult to understand, debug, maintain, and extend (Dijkstra 1968).

In parallel, an alternate paradigm of functional programming languages evolved out of mathematical logic and recursion, with languages such as LISP released in 1959 (Turner 2012). LISP used many small isolated functions with if expressions and recursion instead of loops, allowing small portions of the overall problem to be implemented quickly and independently. Ideally, each function was implemented without any internal variables and with a single if expression similar to a mathematical formula. Each function was “side-effect free,” meaning that there were no variables or structures outside the function that were affected by actions inside the function.

While functional programming languages such as LISP were used mainly in universities, the underlying concepts of small isolated independent functions and hierarchical decomposition were included in the paradigm of structured programming languages (Dijkstra 1972; Knuth 1974) and embraced by industry (Yourdon and Constantine 1975). Software developers were encouraged to use hierarchical decomposition and structure charts (Yourdon and Constantine 1975) to create many small procedures (functions and subroutines) with no global variables. Each of these procedures performed a single task, could be tested independently of the rest of the code, and could be reused in other parts of the code while avoiding global variables. Pass-by-value parameters were used whenever possible to further isolate these routines. Procedural or structured programming languages of this period typically included PL/I, ALGOL, and C.

As early as 1960 there were over 70 languages in existence, and by 1971 there were 164 (Sammet 1972). Sammet identifies the period from 1960 to 1970 as the decade in which the programming language field matured. Higher-level languages became more widely used than machine-level coding because they made it possible to specify a problem solution in terms closer to human language.

By 1972, most universities in the USA and Australia had established computer science or data processing (which later evolved into information systems) degree programs. The majority of the computer science degree programs offered ALGOL, FORTRAN, or LISP, while most data processing programs offered COBOL. In Britain, BASIC was also widely used. During the late 1960s, departments experimented with a variety of other languages like PL/I.

The mid-1970s brought about the introduction of the microcomputer. These machines came with BASIC installed, and while that revolutionized the teaching of computer programming courses in high schools, the trend did not widely impact university programs. Instead, in the 1970s many universities adopted Pascal for use in their introductory programming course. Even as late as 1996, a survey of programs accredited by the Computing Sciences Accreditation Board found

that 36% of the responding institutions listed Pascal as their first language (McCauley and Manaris 1998). The use of Pascal in academia was eventually supplanted by other languages beginning with C and C++ and eventually shifting to Java and C#.

The 1980s continued to experience an increase in the number of available languages. Tharp (1982) reviewed several comparison studies of programming languages including FORTRAN, COBOL, JOVIAL, Ada, ALGOL, Pascal, PL/I, and SPITBOL on the basis of their support of good software engineering practices, availability of control structures, programmer time required for developing a representative non-numeric algorithm, and the machine resources expended in compiling and executing it.

The structured programming paradigm began to give way to the OO paradigm in the early to mid-1990s as languages supporting OO became widely available. The emergence of the OO paradigm accelerated more extensive use of event-driven programming. In the event-driven programming paradigm, program execution flow is controlled not by pre-defined software constructs but rather by “events” that might be generated by a user clicking a mouse, an external event from the network, or by a timer.

Additional programming paradigms have emerged over time, including relational, functional, constraint-based, theorem-proving, concurrent, imperative, declarative, graphical, reflective, context-aware, rule-based, and agent-oriented (Wampler and Clark 2010). Today’s applications, however, are seldom homogeneous and combine aspects from several different paradigms. Many complex systems consist of a variety of subcomponents that require a mixture of technologies. Therefore, using a single programming language and paradigm is becoming less common, with a movement toward multi-paradigm programming in which the heterogeneous subcomponents are each implemented with the appropriate paradigm. This may be accomplished through the use of multiple languages, an approach referred to as polyglot (“many tongues”) programming (Wampler and Clark 2010).

Multiparadigm programming can also be achieved using a programming language designed to support multiple paradigms such as C++, which supports features from multiple paradigms including classes, overloaded functions, templates, modules, ordinary procedural programming, and macros (Coplien 1999). There are also various experimental programming languages that combine multiple paradigms.

Observations

This entry has provided a brief introduction to computing languages. Subsequent entries will discuss the selection of programming languages for higher education courses, followed by teaching software design techniques in university courses, comparative languages, teaching mobile computing, informatics education, health informatics education, approaches for teaching agile methodologies, and teaching robotics courses.

Teaching Machines

Eric Bruillard
Laboratoire EDA, Université Paris Descartes,
Paris, France

Synonyms

Teaching machines are mechanical, electrical, or other automatic devices that present items of information in planned sequence, register users' response to each item, and immediately indicate the acceptability of each response. The best known are from Pressey, Skinner, and Crowder and follow general principles of programmed instruction.

Introduction

A teaching machine can be considered as any mechanical device used for presenting a program of instructional material. Since antiquity, instruction has relied on machines as teaching aids (Buck 1989). Sometimes they are referred to as teaching machines, but these devices are associated with a particular type of educational purpose or activity (e.g., training soldiers). Teaching machines have a universal character, obeying a program.

According to the history of teaching machines (Stolurow 1961; Benjamin 1988; Bruillard 1997; Januszewski 2001, p. 33; Fernster 2014), Thorndike (1912) provided the rationale for teaching machines and programmed instruction.

If, by a miracle of mechanical ingenuity, a book could be so arranged that only to him who had done what was directed on page one would page two become visible, and so on, much that now requires personal instruction could be managed by print. Books to be given out in loose sheets, a page or so at a time, and books arranged so that the student only suffers if he misuses them, should be worked out in many subjects. (Thorndike 1912, page 165)

But how to create books whose contents would only be revealed at the right moment, according to the reader's understanding, as attested by the actions it would be asked to perform, when a

book gives direct access to all its contents? For this reason, it was necessary to develop mechanical or electrical machines and to design very specific books (the scrambled books).

Teaching Machines: Pressey, Skinner, and Crowder

The machine built by S. L. Pressey in 1926 is considered to be the beginning of programmed instruction. This machine consisted of a window with questions with four possible answer choices and four keys. To select one of the proposed answers, simply press the corresponding key down. If the answer was correct, the next question would appear, otherwise the original question would remain in the window and you would have to try another key until you get the correct answer. A system was in place to keep track of the various provided answers. In addition, using a simple lever, the machine was transformed into a self-test device to obtain a score that was retained (Fig. 1).

Following Pressey, other machines were developed, tested, and proven to be effective, designed

Teaching Machines, Fig. 1 Exterior of Pressey testing machine, manufactured circa 1930 (photograph by User: Gomer Bolstrood, September 7, 2006). The first testing machine (1928) had only four keys (see Watters 2015) (https://en.wikipedia.org/wiki/History_of_virtual_learning_environments#/media/File:Pressey_Testing_Machine_1.jpg)

to automatically provide feedback. Teaching machines of all kinds proliferated; since in 1936, between 600 and 700 machines had been patented in the United States (Gilman 1972). It seemed to be well established that learning required feedback, and a simple extension of this outcome revealed an interest in controlling learning through mechanisms that automatically provide feedback to the learner. One of the major weaknesses of traditional teaching, which is the gap between the student's output and the correction of his or her work, had to be eliminated. Attention was paid to the equipment, but later on, especially to the program that became the heart of the device.

The father of the programmed teaching is the American psychologist B. F. Skinner, which is part of the tradition of behavioral psychology. In his 1954 article "The Science of Learning and the Art of Teaching," he states that effective learning is based on the following principles: active participation of the subject, short sequences, gradual progression according to the student's rhythm, immediate verification, and correct answer to the question asked. He developed a teaching machine displaying the material to be learned in small pieces, ordered in a logical sequence. Each of them contained some statement with blanks or a question which required the student to construct a written response. The correct answer was given as soon as the student finished writing, giving an immediate feedback. Adopting positive reinforcement, errors were supposed to be very rare (Fig. 2).

In Skinner's school, the learner's response is an integral part of the learning process and a legitimate end in itself. Crowder (1962) represents another school, relying on differential psychology, interested in taking into account the learner's response to monitor the course. In the first case, we rely on the reward of the subject around a good answer, and error is to be avoided; in the second case, on the principle of making the student acquire mental mechanisms likely to make him/her find the correct answer, error is used to control the student's progress.

Crowder produced electrical machines for implementing his programming method called

Teaching Machines, Fig. 2 Teaching machine, designed by B. F. Skinner (https://commons.wikimedia.org/wiki/File:Skinner_teaching_machine_01.jpg)

branching or intrinsic programming. But he also produced a series of books called scrambled books. To do this, it was necessary to dissociate the logical structure from the content and the physical structure constituted by the printed pages. According to this model, many "scrambled books" have been designed, following the programming principles stated by Crowder: presentation of information followed by a question offering several possible answers, each of which is associated with a page number for continue reading (Fig. 3).

In a scrambled book, each page (or portion of a page) is a unit. The student begins in page 1, and he is asked a question to which several alternatives are given. Depending on which alternative he selects, he is directed to a subsequent page where his error is corrected or where he is introduced to the next part of the sequence.

In the middle of the 1960s, according to Ted (1965), there were about 100 models of teaching machines in various stages of development, of which about half were in limited or full production. These machines may range from a device scarcely more sophisticated than the traditional student workbook to a complex mechanical and even electronic tutor that presents not only written but audiovisual material (e.g., the Crowder Auto-Tutor Mark II).

Teaching Machines, Fig. 3 Auto Tutor, Crowder (<http://deste.umons.ac.be/cours/thappracredite/module6a-2.htm>)

Main Characteristics of Programmed Instruction

If a teaching machine presents information and questions to the user, registers the answers, and indicates whether these are correct or not, very different ways of functioning corresponding to different underlying theories are at work: linear programming with constructed response for Skinner programs (the answer is not given; the student is expected to construct it), linear programs with multiple choices for Pressey, and branching programs for Crowder. However, four main principles of programmed teaching can be underlined:

1. *The principle of structuring the subject to be taught:* the subject is broken down into elementary units; the difficulties must be fragmented according to the principle of small steps.
2. *Adaptation principle:* the progression is carried out in small steps, and the pace of progress is that of the pupil. A programmed teaching must be experienced until it “works.”
3. *Principle of stimulation:* active participation of the student, asked with questions to which he

or she must provide an effective answer, whether it is constructed or only chosen from among several proposed. This is the principle of effective packaging used by Skinner. Interactivity is a basic principle of programmed teaching.

4. *Principle of control* and immediate knowledge of the answer. New behavior is acquired more quickly if there is reinforcement.

Development of Teaching Machines and Programmed Instruction

Based on the general principles described above, programmed education has developed in many countries, in Europe and in the USSR: Pask, Landa, Talyzina, etc. (see Bruillard 1997): research was conducted, books were published (more than 300 books in programmed form in early 1970s), and lists of teaching machines were provided.

Many advantages to the use of teaching machines were underlined. They were particularly considered useful in subjects that require drill, such as arithmetic or a foreign language. Users could proceed at their own pace and also had an opportunity to review their work.

However, programmed teaching and teaching machines were heavily criticized in the late 1960s. The scrambled books are gone. Research runs up against a form of complexity barrier that is present in the most classical tasks of programmed teaching: analysis of the structure of the content to be taught, learning theories, and management of individualization.

In a desire to mechanize teaching, the computer will make it possible to go far beyond the first models resulting from programmed teaching. Dissociating the logical structure and physical structure and linking them by an addressing system led to the computers, machines adapted to this task, which also prevent possible “cheating.” Many CAL (computer-assisted learning) software adopted the model of the scrambled book.

Artificial intelligence led to intelligent tutoring systems research in the 1970s and 1980s.

Perspectives

A teaching machine is mainly a mechanical, electrical, or other automatic device that presents the user with items of information in planned sequence, registers his or her response to each item, and immediately indicates the acceptability of each response.

This is reflected in the many educational applications that can be found today on computers, tablets, or smartphones. But there is no longer a general scientific program underlying these applications. Some authors (as McRae and Bower 2013) predict a sort of rebirth of the teaching machines with new digital machines and their extraordinary capacities; the possibility to capture, treat, and analyze lots of data (big data); and the progress of IA allowing designing very detailed learning models (deep learning). An essential difference is that these machines should be able to provide personalized training for a large population. But that is another story.

Synonyms

Architectural pattern; Design pattern; Development environment; Framework; Software architectural structures; Software architecture; Software design techniques

Definition

Software design techniques focus on reusable software architectural structures such as frameworks and design patterns used to facilitate software development. Software design techniques go well beyond both programming best practices and software design guidelines like cohesion and coupling.

Introduction

Large scale reuse of software architectures and detailed design are made possible through the use of design patterns and frameworks, respectively. Design patterns support reuse of software architecture and design, while frameworks support reuse of detailed design and code (Crawford et al. 2006).

Any academic program responsible for teaching software design concepts must continually

seek approaches by which to improve the ways in which students are prepared for the work force. Software design concepts such as design patterns and frameworks are often underemphasized in information systems and computer science curricula. “Textbooks frequently take the approach of demonstrating how to use a particular library or toolkit, spending little time discussing the structure of the program or architectural patterns like MVC” (Hanson and Fossum 2005, p. 120). The IS 2010 Curriculum Guidelines (Topi et al. 2010) state that graduates of undergraduate IS programs should be experts in high-level design of enterprise architecture. “Although the knowledge and skills that IS graduates need have recently moved significantly in the direction toward higher levels of abstraction, individual skills related to design and implementation are still essential for IS graduates” (Topi, p. 20). The Computer Science Curriculum (ACM 2013) guideline includes eight core hours dedicated to design topics such as design patterns, software architecture, structured design, and object-oriented design, but many programs fail to adequately emphasize each of those topics.

Students are often so focused on learning programming language syntax that they fail to see the big picture of applying that language to solving real problems (Hundley 2008). Development of their problem-solving skills takes a back seat to learning the minutia of a language. Thus, when students take a course in which design topics are covered, instead of focusing solely on those design topics, the instructor must spend valuable time introducing students to the concepts associated with designing a large system.

Review of Design Patterns, Frameworks, and MVC

Design Patterns

One widespread program development paradigm is the use of design patterns. Design patterns represent the embodiment of best-practice programming and support reuse of successful software

architecture and design by “capturing the static and dynamic structures and collaborations of successful solutions to problems that arise when building applications in a particular domain. Patterns explicitly capture expert knowledge and design trade-offs and make this expertise more widely available” (Crawford et al. 2006).

The use of design patterns is a fairly recent addition to software development. They were first proposed in an OOPSLA-87 Panel Session by Cunningham and Beck (1988), who in turn attribute the idea to the architectural work of Alexander et al. (1977). The concept went relatively unnoticed until the seminal piece by Gamma et al. (1993), in which they formalize the concept of design patterns and propose a design pattern template.

The concept of design patterns is elaborated upon by Astrachan et al. (1998), Hundley (2008), Reiss (1999), and Wallingford (2002). A design pattern is a documented solution to a specific problem used to guide a designer. It presents the interaction of data and methods in multiple classes, describes the implementation of classes and features needed for the interaction, and offers insight to problems that may arise in the application. Design patterns are reusable solutions that designers can apply, with possible modifications, to an application.

A design pattern is generally defined as a schema comprised of four parts:

- Name – provides a handle and a vocabulary for discussion and use of the pattern.
- Problem – provides a context in which the pattern is applicable.
- Solution – describes the components of the pattern and their interaction, including their responsibilities, relationships, and collaborations.
- Consequences – trade-offs and implications that arise from adapting the solution to the problem.

Design patterns are uniquely named and are written in a consistent format that makes it possible for designers, developers, and others to communicate using a common vocabulary

(Khwaja and Alshayeb 2015). They are typically written in design-pattern specification languages that document the abstraction detailed in the design pattern rather than capturing algorithms and data (Khwaja and Alshayeb 2015).

Over the last two decades, software professionals have embraced patterns as a means of recording and sharing expert knowledge for building software. It seems sensible that students should be exposed to this approach to design.

Experience often makes the difference between being a poor and good designer. When determining a solution to a problem, good designers rely on prior experience by relating the problem to those they have previously encountered. Design patterns are the results of formalizing this experienced-based knowledge and document the stereotypical techniques and program structures used by veteran programmers. Each pattern describes a particular scenario with constraints, motivations, and relationships and provides a relatively optimum solution to these problems (Tao et al. 2015). Recent studies by both Hussain et al. (2017) and Gravino and Risi (2017) found that there is a significant relationship between design pattern usage and greater software quality.

Shortly after their seminal conference paper, the book *Design Patterns: Elements of Reusable Object-Oriented Software* was authored by Gamma et al. (1995). The 4 authors, now known as the Gang of Four, presented 23 design patterns for purposes such as object creation, modification, reuse, implementation, and data sharing. These are used as the foundations of all other patterns. These original 23 patterns have since been expanded upon, but there are three basic patterns that are especially useful to understand. They are Singletons, Factories, and Builders.

Singletons

In a singleton design pattern, the instantiation of a class is restricted within a single object, and that object can be shared across an entire application. Singletons are useful when one and only one persistent instance of an object is needed for the entire lifetime of an application. The instance of the object is not created until it is needed. When it

is requested, a single object from the class is created and kept inside the class itself. This often is accomplished using a private constructor, ensuring that the only way to create the object is from within the class itself. This makes it possible for the class itself to make sure no more than one object is ever created.

While similar effects can be attained using a static class, static classes can have only static methods, meaning they are purely procedural. Because the singleton is truly object-oriented, it offers several advantages. For example, unlike a static class, a reference to the single instance of a singleton can be passed as a parameter to other methods, and that parameter can be treated like any normal object. Furthermore, a singleton can implement interfaces, inherit from other classes, and permit inheritance. While less competent programmers sometimes use singletons to replace global variables, this is clearly a narrow or incomplete use and often considered poor practice.

A singleton is commonly used when an application has a set of data that does not change often but is frequently referenced. Constantly returning to the data store to retrieve data that has not changed is inefficient and an extensive and unnecessary use of resources. Using a singleton, we can dramatically decrease the number of times we retrieve data that has not changed. A painter's palette serves as an analogy. It does not make sense to go back to the paint tube each time we need a color. Therefore, we would keep an instantiation of all of the different colored paints we need on the palette and only refresh them when the paint is "dirty." Examples may include a list of user permission roles, organizational categories (such as gender or age groups), or even a collection of data access layers for multiple data sources.

Factories

In a factory design pattern, objects are created without exposing the creation logic to the client. The goal is to have a single location where all instantiations of a class or series of classes are defined. The objects for these classes cannot be created on their own; they can only be requested

from the factory class. Using a constructor that has namespace access modifiers will facilitate this behavior. Factories create not only consistency in how objects are created, but it also creates a single place to go when there are problems. Rather than scouring your entire project to find each line of code in which you created a certain object, you simply go to the factory where it was "assembled" and fix the problem there. It will now propagate that fix through your entire solution. The simplest analogy for a factory is an actual factory. For example, a factory that makes gears will make a specific type of gear. If you want one of those gears, you must request it from that factory, and it will be made for you. If a problem is found with that type of gear, it is as simple as going to the factory and having them fix their error there, and all future gears from that factory will no longer have that problem. Examples for a factory may include a Roster class that is the only place where new employee objects can be created or a Messaging class where all messages sent to users are created.

Builders

You would use the builder design pattern when the construction of an object is complex or has a specific order. Builders are like factories. The main difference being that the builder pattern is used to create complex objects with lots of parts and/or when the order in which the parts are put together matters; however, factories are for less complex construction processes. A simple analogy for a builder could be a construction firm. For example, if you want a house, you might go to the construction contractor and request a house. The house will have lots of parts that they will need to construct because a house has a lot of objects that depend on other objects (inter-object dependencies). The builder's job is to put all of these dependent objects together correctly and in the right order to make this complex object that is a house. The order matters because you cannot put the roof on the house before you have erected the walls, nor can you erect the walls until you have laid the foundation. An example case for a builder may be when you need to build a report that requires particular components of the report to

be retrieved before you can retrieve additional related data.

Frameworks

Frameworks facilitate reuse of detailed design and code. “A framework is an integrated set of components that collaborate to provide a reusable architecture for a family of related applications” (Crawford et al. 2006).

A framework defines a family of related applications and contains elements that are common to those applications (Tao 2002). Frameworks provide structure by enforcing naming conventions (directories, files) and rules for constructing a system. They also provide components that aid in the construction of a system. Application developers extend the framework to build custom applications. Thus, a framework is basically a development environment in which programmers can develop applications of all types much easier and faster, including Web applications. A framework may consist of source code libraries, utilities, plug-ins, development models, and a wide range of tools, the purpose of which is to accelerate the application development pace.

There is a core of recurring themes in most frameworks (Caspersen and Christensen 2008):

- The framework delivers application behavior at a high level of abstraction.
- A framework provides functionality within a well-defined domain, i.e., frameworks address specific domains like graphical user interfaces, gaming, insurance, telecommunication, etc.
- A framework defines the interaction patterns between a set of well-defined components/objects. In order to use the framework, the developers are required to understand these interaction patterns and must program in accordance with them.
- A framework is flexible so that it can be tailored to a concrete context, provided that context lies within the domain of the framework.
- A framework makes possible the reuse of code as well as reuse of design.

MVC

The Model-View-Controller (MVC) pattern is probably the most widely known pattern. Rather than being a design pattern, it is generally agreed that MVC is an architectural pattern. While design patterns typically focus on components of a subsystem and their relationships and collaborations with each other, architectural patterns focus on the larger subsystems of an application along with their relationships and collaborations with each other. (Note that the preceding clarification can be found with multiple attributions on the Internet.)

MVC has proven to be an important architectural pattern for facilitating the development, debugging, and maintenance of systems. The origin and details of the MVC are explained by Tao (2002), Morse and Anderson (2004), and Hanson and Fossum (2005). It was developed for Smalltalk-80 at Xerox PARC in the late 1970s as a means of facilitating the development of systems with graphical user interfaces (GUI). MVC was found to be particularly appropriate in applications that provide multiple views of the same data. It has been successfully applied to the development of client-server and web-based systems (Gacimartín et al. 2011; Kasik and Stankus 2010). MVC has been used and adopted to varying degrees in most GUI class libraries and application frameworks, and it has become the central feature of many modern interactive applications (Morse and Anderson 2004).

The key idea behind the MVC pattern involves separating user interfaces from the underlying data represented by the user interface. Thus, the MVC pattern, as shown in Fig. 1, separates the three main components of an application: Models, Views, and Controllers.

- The Model contains the data collected on the client side as well as application methods to access and manipulate the data. This includes both the information represented by the View and the application’s business logic that changes this information in response to user interaction. Data models are typically databases or XML files. The Model provides data to the other two components.

**Teaching Software
Design Techniques in
University Courses,**
Fig. 1 MVC patterns
(Chao et al. 2013)

- The View is responsible for the visual display of the application. The View component contains scripts that render the View selection for the user and contains all the graphical user interface components that receive input from users. In addition, the View is responsible for displaying output created by the Model for the user.
- The Controller dictates how the application behaves by acting as the primary event handler that responds to events generated by the user through the graphical components in the View. The Controller is the glue between the data models and the views. It connects the presentation (View) and data layer (Model) to each other and coordinates activities between them. Controllers process user input and update the Model and View appropriately. Every controller has a number of actions, and each action will, in general, generate a View for the user. Actions are grouped into controllers based on some criteria, generally a common data model or purpose. Every action is responsible for taking the relevant data, doing whatever controller-specific processing needs to be done, then passing it to the View.

In general, the Model manages application data, the View presents the user interface, and the Controller handles events for the View.

Separating the internal data models from the interface views that set or display the data allows models to be represented by a variety of views. Further, the model's algorithmic logic is distinct from the management of the view, thus leading to a simpler program design.

The views must maintain their own state, and there must be communication by which the models update the views or the views update the models. Such communication may be initiated by internal processes or by the user-initiated events. Events may also trigger internal processes that result in updates of the models and/or the views.

Encapsulating the three abstractions (Model, View, and Controller) into separate classes leads to multiple desirable outcomes:

- The same set of business logic (Model) can be used with multiple views to provide different user interfaces for the same underlying application. These interfaces could include web interfaces or traditional GUIs, or could be developed in multiple languages or with different sets of user permissions.
- The impact of user interface changes is minimized. The application's "look" can be drastically altered without modifying data structures and business logic.
- The reusability of domain objects is increased (Tao 2002).

- By separating the model from the view and controller, separate teams of developers can work on each component, either serially or in parallel.
- Automated test harnesses can be used to perform extensive unit testing on the business logic without tedious testing of the GUI.

The MVC pattern has proven to be very useful in industry and also can be effectively used in student projects using either traditional or object-oriented methodologies. Web applications, mobile applications, and other interactive software systems can benefit by being designed with the MVC pattern logic.

Benefits of Patterns and Frameworks

The motivation for using design patterns and frameworks is explained by Ali et al. (2011), Gamma et al. (1993), Vuksanovic and Sudarevic (2011), and Wick (2001).

Little software of any consequence is developed using only a programming language. With the emergence of modern software development methodologies and related frameworks, many developers began to harness their advantages, such as faster development, enhanced security, availability of useful and standardized libraries, simpler organization of work in development teams, and clearer structure of code due to strict conventions and use of patterns that encourage separation of domain logic, user interface, and the data processing model.

Design patterns have become an extremely effective tool with which to solve software development problems because they represent language and application independent solutions to commonly occurring design problems. Developers familiar with design structures can apply them immediately to design problems without having to rediscover them. Less experienced software developers can benefit from design patterns by taking advantage of the lessons and outcomes learned by more experienced developers. Design patterns also facilitate the reuse of successful architectures, because expressing proven techniques as design patterns

makes them more readily accessible to other developers.

Most commercial software is developed using a framework by extending and customizing the default, generic functionality that it provides. Thus, frameworks not only help in understanding and constructing real-world applications but also provide additional reusability of both design and implementation. Frameworks offer numerous technical and organizational advantages over classical development methods, such as faster development and cleaner application structure. In addition, programming using frameworks is more comfortable for developers, since frameworks provide for many common programming tasks.

The use of frameworks reduces time spent on code maintenance and future development in many ways:

- Frameworks provide numerous libraries and helpers, making it possible for developers to achieve comparable functionality with less code, so the software is more easily maintainable.
- Software unit testing, defined as a process that includes the performance of test planning, the acquisition of a test set, and the measurement of a test unit against its requirements (IEEE 1986), is facilitated by the framework rather than performed manually.
- Those tasked with software maintenance will require significantly less time deciphering existing code developed via a framework, thanks to the Model-View-Controller pattern and other coding conventions.
- Future improvements, such as protection measures against future hacking attack techniques and yet unknown vulnerabilities, may be addressed by future releases of the framework and thus may only require upgrading the framework to a newer version.

Additional Applications of Patterns and Frameworks

While patterns and frameworks improve software quality, they can also be used to address specific

needs. Esakia and McCrickard (2016) discuss the use of patterns and frameworks in the development of mobile apps. Prabhakar et al. (2017) show that the use of various design patterns in the development of various components of data mining applications can improve quality attributes such as reusability, maintainability, extensibility, adaptability, and performance. Colesky et al. (2013) and Van Niekerk and Fletcher (2015) explore how design patterns can play a role in introducing security during the groundwork of applications by influencing coding habits of developers. Suphakul and Senivongse (2017) discuss the use of privacy design patterns for the development of privacy-aware applications. A large variety of additional applications for patterns and frameworks can be discovered with an Internet search.

Motivation for Teaching Design Concepts Via Frameworks

One of the most beneficial aspects of design patterns is their educational nature. Creating a design pattern requires a high degree of explicitness. Wallingford (2002, p. 152) explains:

Writing a pattern requires the author to state explicitly the context in which a technique applies and to state explicitly the design concerns and trade-offs involved in implementing a solution. These elements of a pattern provide significant benefits to the reader, who can not only study the technique that defines a solution but also explore when and how to use it.

Astrachan et al. (1998, p. 153) assert that “patterns are an essential programming and pedagogical tool.” Wallingford (2002) agrees, calling for further studies into ways in which to use patterns effectively in teaching.

Christensen and Caspersen strongly advocate frameworks in teaching, and provide many convincing arguments for their use topic (Caspersen and Christensen 2008; Christensen 2004; Christensen and Caspersen 2002). The programming context faced by most programmers today is radically different from the one that existed a decade and a half ago. Being a successful developer is no longer a question of being a good

programmer, but just as much a question of understanding complex interaction patterns in frameworks and being able to design in accordance with their guidelines. Developing any realistic software requires the ability to identify proper software frameworks to reuse as well as the skill to write the specialized code for the task at hand.

This means that we need to teach new skills to our students in addition to the old ones. Writing even a simple program that has a graphical user interface using a framework is radically different from traditional approaches. The event-driven protocol in a framework requires students to understand the complex interplay between framework code and their own code. Students must be adequately trained to make software reuse their first development option.

While the main motivation for teaching frameworks focuses on the obvious need to teach students about the techniques that govern modern software development, there are additional pedagogical aspects that make frameworks a worthwhile.

- Student motivation: If students must program everything from scratch, then the workload and complexity rule out developing software that in any respect compares to the sophisticated and appealing programs that they are used to from, for example, the Windows platform. However, a framework used in the classroom defines the skeleton of an application that can be customized by an application developer and can provide the “bells and whistles” that makes the effort invested by the student look more appealing or “professional.” The “return on investment” is simply greater for the student.
- Setting an example: A well-designed framework can serve as an exemplary use of design patterns by making it clear that design patterns work together and that patterns really define roles.
- Gentler learning curve: Simple frameworks can illustrate basic concepts in framework theory and practice in a gentle way as stepping stone for learning more complex GUI frameworks. It is important that students learn the basic concepts and techniques relating to frameworks.

- Developing is a reuse business: Students must learn that software development entails more than producing code but also involves locating and incorporating reusable assets. Frameworks illustrate many design patterns and reinforce the concept that patterns express roles in a collaboration pattern rather than objects that are to be copied into a design. Frameworks exemplify the reuse of design as well as code, whereas design patterns demonstrate only design reuse. Thus, they serve to strengthen the concept of programming as a process of reuse as well as coding.
- Workforce ready: Frameworks have already made an impact on how industrial software is developed in a cost efficient and reliable way. Graduates should be familiar with the basic concepts and techniques relating to frameworks. Further, students are better prepared for the workforce when exposed to commercial tools.
- Object concepts. Frameworks utilize best practices of object-oriented programming. Requiring students to read and understand parts of frameworks will provide them with important insights in how to structure complex systems in a master-apprentice fashion.
- Responsibility-driven design: An MVC framework is an excellent example of how responsibility-driven design influences the identification of classes and the assignment of responsibilities to those classes. While many students have an initial expectation that the GUI should be integrated with the data since they are so closely related, an MVC framework provides an intuitive and concrete example of how the separation of manipulation and display can result in a powerful and flexible software design (Wick 2001).
- Become familiar with multiple widely used patterns and get hands-on experience developing simple applications to illustrate learned patterns.
- Develop the ability to consciously apply proper patterns in future software design efforts.

Summary

Several studies have made the case that current curricula neglect design patterns, architectural patterns, and frameworks. While many studies have established the benefits of patterns and frameworks, there is a need for additional research to find ways in which to incorporate these in teaching.

There are many benefits to incorporating patterns and frameworks in the classroom. By introducing students to patterns and frameworks during their education, they gain not only an appreciation for design concepts like separating the user interface from the underlying data and logic but also exposure to commercial software tools that enhances their future marketability.

Serious Games

Play is widely considered to be the most natural form of learning. According to Vygotsky, play contains all developmental tendencies in a condensed form and is in itself a major source of development (Vygotsky 1978). In an online environment, computer games provide individuals with opportunities to play. Most of these games are designed primarily as entertainment. However, some games are meant to be more than just entertainment.

Serious games include all forms of games that have a serious intention, such as *educational games*, which have the intention to impart specific skills or knowledge to the player. In many areas it is difficult to reach the youth in an effective manner which engages them in high-quality educational material. This can act as an obstacle to learning (Boyle et al. 2016). Educational games provide an important instructional medium in such areas where it is difficult to engage young learners.

Benefits of Educational Games

Educational games have many potential beneficial outcomes for learning. A review of current literature showed that the most frequently occurring outcome was knowledge acquisition. This is followed by perceptual and cognitive, affective, and behavior change. Some papers also report outcomes related to acquisition of soft skills and social skills (Boyle et al. 2016).

One of the most important aspects of educational games is the reported increased interest in the subject matter and the ability to motivate youth to learn (Petri and Gresse von Wangenheim 2017). These games provide a fun and safe environment, where students can learn from their own mistakes and practical experiences without real-world consequences. The situated learning environments of such games provide an increase in authentic context for learning, more authentic activities, access to the skills of experts, multiple roles and perspectives, opportunities to collaborate in knowledge construction, support for scaffolding, and many other benefits (Mouaheb et al. 2012).

Application Areas

Educational gaming has been used in many subject areas; however, their use is currently most popular in STEM disciplines (Boyle et al. 2016). Examples include games in many game genres, including simulation, role-playing, drill and practice, MMORPGs, strategy, puzzles, and adventure games.

Future

The use of educational games is currently experiencing massive growth. This can be attributed to the growing body of evidence for the efficacy of such games, as well as the increased availability of easy-to-use game development tools, which is driven by the large growth in the global computer game market. One can thus expect to see many more of these games at secondary school level in future.

Teaching with a Logo Philosophy

What is programming? In a narrow interpretation, programming means communicating with a machine using a language that it “understands.” The goal of such a communication is to instruct the machine to do what the programmer wants. Unfortunately, programming languages are often poor in their expressive power and very technical in their syntax. Many of them seem more like mysterious encodings than languages one would like to use when expressing one’s thoughts. For this reason, in the past, many programming courses failed at the stage of their introduction. It is easy to design programming courses that would frustrate almost any pupil. As a consequence, several countries excluded programming from general education.

On the other hand, in a deep and broad interpretation, programming means problem-solving, including communicating and explaining the discovered solution strategy in an exact way or to quote Donald Knuth (1996):

Science is what we understand well enough to explain to a computer. Art is everything else we do.

This is a chance for applying the basic principle of constructivism, i.e., for *learning by doing* (Piaget 1971). If a problem is viewed as a set of problem instances possessing the same abstract concept, then problem-solving can be seen as a process consisting of three phases:

- *Phase 1.* Trying to solve several concrete problem instances, one after the other, in order to gain some involved expertise in solving the problem. Constructing a solution to a given

problem instance and verifying its correctness are nothing more than learning by doing.

- *Phase 2.* When a general method to solve all instances of the given problem has been discovered, the strategy is described in a metalanguage and then in a programming language.
- *Phase 3.* The method implemented as a program is run on a computer in order to observe its behavior and to verify its correctness in terms of expected functionality. The product of that activity is a program, a *thing that works*.

All three phases correspond to constructive work. Repeating them in a loop can improve both our expertise and the resulting program. Extending the functionality of a program increases its applicability to new situations (i.e., tasks) and makes its description more understandable or its execution faster. All this can be turned into a never-ending story of improving products, just as in real live.

Why did Seymour Papert consider teaching programming as a chance for deepening and enriching the concept of classical constructivism and, as a result, introduce the term constructionism? (A discussion of the differences between the two terms is given by Ackermann (2001).)

Papert (1999) said that:

We learn better by doing. . . but we learn better still if we combine doing with talking and thinking about what we have done.

This means that humans learn by doing, reflecting about their doing, and reflecting about the products of their doing. Programming allows for reflection because it is possible to test the functionality of programs by observing their behavior and to discuss observations with others. Papert (1999) adds that:

Life is not about ‘having the right answer’ – or at least it should not be – it is about getting things to work.

Getting things to work is the critical term. *Making our products work* is the main philosophy behind this form of education and behind teaching programming using *Logo*. Papert refers to

constructionism as *learning by getting things to work*. One has to see the potential of an open end in education based on constructionism. The goal is not to learn how to apply and maybe – in a better case – to understand a specific method for solving a class of problem instances. Instead, it is possible to truly discover a method to solve a given problem. This is not about discovering a special one, but any working or even only partially working strategy, highlighting the creation of something so original that it is not described in any textbook and surprises teachers. Striving for a real-life experience enables pupils to learn about the process of searching for a solution.

An Advanced Concept of Logo as Merging Constructionism with Critical Thinking

The following more general view on teaching programming with *Logo* philosophy builds upon and enriches Papert’s concept of *learning by getting things to work* in the root of the matter. Critical thinking in education is concerned with the following (Hromkovič 2018b):

Do not teach the products of science as facts, models, or methods or, still worse, how to use technical devices. Rather teach the processes of their discovery.

In particular, this highlights the need to teach pupils:

- How to develop experience by sampling data, observing processes, and undertaking experiments (for instance, trying to solve specific instances of a given problem)
- How to formulate a hypothesis based on prior experience and how to verify its correctness
- How to use knowledge to create products with a desired functionality and how to test them under realistic conditions
- How to reiterate the previous points in order to correct and deepen the understanding and in order to improve the functionality of the products

This approach aligns with the philosophy of *getting things to work*; it focuses on supporting the growth of the pupils' expertise by running processes of discoveries and by creating things that work in an expected way.

Combining critical thinking with constructivism fits the vision of Papert (1999):

This is not a decision about pedagogic theory but a decision about what citizens of the future need to know... The rapid and accelerating change that marks our times means that every individual will see bigger changes every few years than previous generations saw in a lifetime. So this is the choice we must make for ourselves, for our children, for our countries and for our planet: acquire the skills needed to participate with understanding in the *construction* of what is new OR be resigned to a life of dependency.

Indeed, it is not possible to tell what exact kinds of jobs primary school pupils are being prepared for, since most of these jobs may not even exist yet and we are not able to forecast them at this point – just imagine a 6-year old in the early 1990s telling you she wants to be a web designer once she grew up. In more detail, future education has to pass on three essential skills to future generations. Children need:

- To view everything as a process of its evolution. To be trained to immerse into the processes of discovering knowledge and developing products for any purpose.
- Not to believe in any presented facts and models without questioning the degree of their credibility and checking the limits of their validity by following the processes of their discoveries. To understand that many things that are commonly referred to as facts merely represent an intermediate state of our knowledge and view them as a challenge to understand things better. Particularly, to be able to recognize misinterpretation and over-interpretation of statistical results. This is a common problem in most sciences that are primarily based on collecting data.
- To view products of technology through the eyes of creators, seeing their strong sides and drawbacks. To think about how products could

be improved or extended in their functionality. To be able to check their functionality by running them under real application conditions.

The concept of *Logo*, invented by Papert and colleagues (Papert 1993), fits these goals. Children gain experience by trying to draw a given geometric picture. They can do so step-by-step, by instructing the turtle to draw the shape piece by piece. This way, they notice immediately when something goes wrong, which offers the possibility to search for an appropriate fix and then continue working constructively. Making mistakes and learning from them is an essential part of the learning strategy – the true real-life learning.

Altogether, children design programs as products of their work and let them run to *discover* to which extent their functionality matches the expectations. This is pure *learning by getting things to work*. The iteration process of correcting, improving, or extending programs is deeply rooted in our past, the key of how people used to work ever since.

A very strong feature of *Logo* lies in the simplicity with which one is able to compose programs modularly. By programming, children learn how languages develop and incidentally *construct* (develop) their own programming language (Hromkovič 2018a, b) by introducing new words. Children teach new words to the computer which then they are allowed to use in their further communication with the machine. The way this can be done in *Logo* is as simple as it gets. Children learn to assign names to their programs, and then they use these names as new instructions, i.e., new words. Letting children develop their own languages is an enrichment to classical language classes, because in programming courses pupils learn to understand languages through their evolution. Later, they can also design some parts of the grammars of programming languages and, by doing this, understand the formal structure of languages even better.

Programming in *Logo* is an iterative and interactive process of constructing programs, running the resulting products, observing their execution,

and finding reasons to continue improving them. This way of learning is beneficial to all subjects of education systems. Papert (1999) phrased the following analogy about good teaching:

The best way to become a good carpenter is by participating with a good carpenter in the act of carpentering.

However, this analogy is somewhat special: in *Logo* philosophy, all problems are open-ended. For each computing problem that can be solved, there are infinitely many different programs solving it. We do not advise the pupils to discover a certain one. To this end, Papert (1999) says:

A crucial aspect of *Logo* spirit is fostering situations which the teacher has never seen before and has to join the pupils as an authentic co-learner.

Vision

Taking *Logo* as a philosophy of education, practitioners can contribute in two ways. One is to improve teaching programming in a way that still strengthens the *Logo* philosophy with the focus on constructionism. The other is to apply the *Logo* philosophy for creating concepts and learning sequences in other subjects. The two aspects are discussed in the following two subsections.

Strengthening *Logo* Philosophy by Teaching Programming

One of the main obstacles in teaching programming occurs in the phases where programming novices start to write longer programs. Frequently, teachers are overwhelmed by the vast number of

pupils requesting help in the process of searching for errors. Giving too many instructions and too much advice comes with the risk of disturbing the learning process. Moreover, the ability to find errors in programs autonomously is an essential part of a programmer's work.

True constructionism in teaching programming means to train the pupils' ability to master the process of searching for errors and correcting them. The goal is to make children as independent as possible while *getting their own products to work*.

Programming in *Logo* primarily means to draw geometric shapes on the screen by moving a turtle. *Logo* programming relies only on four simple commands (see Fig. 1):

- Moving forward a certain distance: forward 100 or fd 100
- Moving backward a certain distance: back 100 or bk 100
- Turning left a certain angle: left 90 or lt 90
- Turning right a certain angle: right 90 or rt 90

As few as four commands are sufficient to create a wide range of different shapes such as squares, spirals, houses, or stars. In order to solve problems like these, novices need to think algorithmically: first, they think of a suitable solution strategy which then they formulate for a computer in a precise description, a program; after that, they execute their program and verify whether their strategy works as intended.

The *Logo* programming environment XLogoOnline (Hromkovič et al. 2017) is

Teaching with LOGO Philosophy, Fig. 1 Basic commands available in LOGO

designed for a young and yet inexperienced audience attending primary school. It is tailored to a curriculum (Hromkovič 2018a) that covers programming concepts such as sequences, repetition, modular program design, and parameters. With a simple and uncluttered user interface, the programming environment is designed not to induce additional cognitive load. This is important since programming is an activity that is strenuous and demanding by nature; children are prone to committing numerous mistakes. All difficulties they encounter fall in either one of two classes: *syntactic* and *logical errors*. Pupils struggling with syntactic errors fail to express their ideas in a way that the computer understands. A program with logical errors can be executed by the computer; however, it leads to unexpected behavior. The XLogoOnline programming environment supports pupils coping with challenges related to both classes of errors.

Challenge 1: Expressing an Idea Such that the Computer Understands It

Programming in a language with formal syntax and rigorous structure requires precision. Unlike humans in natural languages, computers are not able to infer meaning from incomplete or incorrect sentences in a programming language, and so they refuse to execute programs that are ambiguous or incomplete.

In order to find out what syntactic errors novices typically commit in *Logo*, an experiment with 180 novice programmers was conducted that ran for 2 h and collected a trace of more than 5000 programs. An analysis for syntactic errors showed that, after an initial exploration phase, incorrect program invocations (due to missing spaces, extraneous or missing arguments, or typos) were among the most common syntactic errors committed by novices (Forster et al. 2018).

As a result of these findings, a methodology that allows for detecting as many syntactic programming errors as possible was integrated into the XLogoOnline programming environment. As the users type, their programs are continuously and automatically checked in the background. Programs which fail to parse are analyzed further to locate errors. Syntactic flaws are indicated

immediately at their corresponding location within the program. Whenever suitable, age- and knowledge-appropriate explanations that tell the pupils how to resolve the issue are provided. This simple and yet powerful mechanism reduces the time spent searching for typos and other syntactic errors significantly, yet the children still learn about the need to express themselves precisely from a syntactic point of view.

Depending on age, typing a program already poses a significant hurdle for novices. Kindergartners, for instance, do not know how to read and write yet and thus heavily depend on spoken words and symbols. For them, programming in written form is too difficult. For this reason, block-based programming can be used until the pupils are proficient enough to work with a keyboard. In block-based programming, children snap together command blocks with semantic meaning. Blocks only fit in ways that comply with the underlying language specification, which eliminates syntactic errors altogether. Block-based programming provides a simplification that allows young pupils to program despite them not reading and writing fluently yet.

Challenge 2: Searching for Root Causes of Unexpected Program Behavior

Syntactic errors cause programs to become non-executable. This is not the case for logical errors; however, they result in unexpected outcomes due to logical flaws in reasoning. Such errors cannot be automatically detected by any computer, and, in order to recover from logical errors, children need to develop proper debugging strategies. First, a debugging mechanism is presented that was introduced into the XLogoOnline programming environment and allows for stepping through program execution manually. Second, the systematic bottom-up problem-solving approach used in a proposed curriculum is presented (Hromkovic 2018a, b; Kohn and Hromkovic 2018a, b). Together, they allow pupils to tackle complex problems and trace logical errors in their programs.

1. As the complexity of programs rises, programmers are more vulnerable to logical errors.

Initially, children execute one command at a time and can observe the effect immediately. Errors are evident and can be corrected on the fly. Later, novices start writing longer programs containing several commands that are all executed “at once.” Figure 2, for instance, shows a sequence of commands that is supposed to draw a square – it is nontrivial for beginners to identify which command caused the problem. Step-by-step, the programmer needs to retrace her or his reasoning and follow the program’s execution mentally. Keeping track of all information (e.g., the turtle’s position and orientation) is difficult and can cause pupils to give up. A stepping mechanism in the programming environment allows for tracing program execution step-by-step and for visualizing important drawing attributes such as pen width, color, and visibility. Command by command, the pupils inspect their program during its execution and hence identify errors as they occur. Figure 3 shows how pupils step through their program, searching for the exact location where an error was introduced.

2. In order to reduce the number of logical errors in the long run, children need to approach problems systematically. This is especially important once their programs grow to a higher level of complexity, such as when they start

using self-developed commands. Reasoning about unexpected behavior in nested program calls is challenging: how is it possible to know where the problem was introduced without carefully inspecting the entire program, including all layers of indirection? Searching for errors under these circumstances is a tedious and cumbersome endeavor. For this reason, pupils can be taught a bottom-up problem-solving strategy: a given problem is first decomposed into subproblems. For each of these subproblems, the children write individual solutions and verify them by running the programs on a computer. Only once the pupils have a working solution to all subproblems do they assemble a solution to the original problem. Figure 4 shows how a grid can be constructed from a simple square that is used to draw a single row of squares and finally the entire grid.

Novices learn to test all their programs for correct functionality before nesting them in new programs. This helps at identifying and resolving errors and leads to a truly constructionist style of programming, where more and more complex structures are created while still keeping track of the underlying connections.

Education Based on Logo Philosophy

For the implementation of *Logo* philosophy or of constructionism for all subjects, a series of books would not suffice. However, the point can be exemplified using mathematics. Mathematics is a language. The motivation to develop mathematics builds upon the desire to have a language with the following properties:

1. *Unambiguous interpretation of each text.* Science needs a language in which each sentence has only one meaning, allowing everyone mastering this language to communicate and understand one another unmistakably. Without such a language, there is no objectivity in science at all.
2. *Verifiable argumentation.* All argumentation in the unambiguous language of mathematics is verifiable by simply following a set of syntactic rules.

This is a starting point for designing courses in mathematics. Fundamentally, mathematics is about developing a powerful instrument for describing and investigating the world. A way to learn mathematics is to gradually discover one concept (i.e., a new word in the language of mathematics) after the other. Each new concept enriches the language and makes it more powerful as a research instrument. New concepts enable us to speak about things that could not be spoken about before and to investigate properties and relationships that could not be discovered before. From an educational point of view, it can be beneficial to discover mathematics in a continuous process of creating a research instrument to examine the real world. Mathematics takes pupils on a journey of discovering our world, and

teaching it in an appropriate way changes the perception of the subject. One implementation example is the history of designing number representations as described in a recent school textbook (Hromkovič 2018c, d).

For teaching computer science without a computer, consider cryptography as an example. This discipline is about 3500 years old and talks about secret writings. Starting with the demand for secret writings, pupils can discover one cryptographic concept after the other, develop their own secret writings, test them, combine them, learn about their drawbacks, break them, and improve them – all in a constructive way (Hromkovič 2018d; Hromkovič and Lacher 2019).

More specifically, cryptography can serve as an example of how to create a spiral curriculum, i.e., revisiting a field repeatedly, and with every iteration deepen the discussion, introducing more and more advanced insights and techniques that are at all times tailored toward the current level of the pupils. In a way, the pupils' increasing understanding of cryptography mimics the development of civilization in this respect.

With the development of permanent storage of data outside the human brain, i.e., the development of written information (which describes the first steps of *digitalization*), the need arose to hide this information from unauthorized parties. The first known cryptographic systems were comparable with what most children would come up with today when inventing secret writings with their friends. However, as civilization progressed, hiding written information meant facing more and more powerful adversaries and therefore coming up with more and more involved strategies.

For instance, in fifth grade, a lesson might start with a riddle: two friends communicate in a secret

way. The pupils are given two messages, one sent from the first friend to the second and one sent back in return; there are no further clues given, just a question of whether what the texts say can be discovered. Deciphering the messages can be done by changing the order of the letters in the texts; e.g., in the first text, the first and second letters are switched, and the third and fourth, the fifth and sixth, and so on; the second text is simply written backward. There is a wealth of possible extensions and discussions, such as coming up with other secret writings that can be broken by others (when possibly accompanied by some clues). This is pure *constructionism*.

Still in a fifth or sixth grade, it is possible to introduce other methods to encrypt a given *plaintext* by, e.g., writing it into a table of fixed size row by row and then writing down the ciphertext as the columns of the table (Hromkovič and Lacher 2019); this is essentially *scytale* (see Fig. 5).

Almost any lesson on cryptography can be made interactive while awakening the pupils' curiosity and ingenuity. And so, after having studied different ways to encrypt texts, it is possible to present the cryptosystem CAESAR (again in the form of a riddle); here, it is possible to introduce the notion of a *key* (although this concept is already present in *scytale*). In CAESAR, the plaintext is encrypted, thus resulting in the *ciphertext*, by shifting the letters of the plaintext by a fixed position i in the alphabet (starting over from A when having arrived at Z). If, for instance, $i = 2$, then any A is mapped to (replaced by) C, B is mapped to D, X is mapped to Z, Y is mapped to A, and finally Z is mapped to B; i is called the *key*. For convenience, the focus can be on the 26 uppercase letters of the English alphabet, and thus there are 25 possible keys.

While CAESAR can already be discussed in grades 5 and 6, in grades 7, 8, or 9, the pupils can start to break it. Due to the very small number

of keys, a simple brute force attack (i.e., systematically trying out all keys) is feasible, which is particularly impressive when combined with an algorithm that tries out all 25 keys and displays the resulting texts in the fraction of a second.

So how to make an encryption more secure? The answer is to have more keys. This leads to the concept of *monoalphabetic* cryptosystems where letters are mapped to arbitrary different letters. This time, there is no fixed distance between a letter of the plaintext and the corresponding letter of the ciphertext. As a result, there are not just 25 potential keys but 26; and this is quite an impressive number with 26 digits.

However, this system can be broken by taking advantage of statistical properties of the language the plaintext is written in. In typical English texts, for instance, the letter E appears most frequently, followed by the letter T, and then A. With this knowledge, the pupils are able to again decipher given ciphertexts (that should be chosen somewhat carefully). And after they see how this can be done, they can try to work on improvements by, e.g., using two different systems for different letter positions of the same plaintext.

But this is not where the spiral ends. There are numerous other systems to discover, to study, to break, and to improve. It is even possible to introduce public-key cryptography at high schools (Keller et al. 2010).

The underlying goal, however, is not to master the use of attacks on famous cryptosystems. This topic can be taught in such a way that pupils see the strengths and drawbacks of the cryptosystems presented and are thus able to design new cryptosystems based on the concepts introduced, to test them, and to try to break them. Depending on their age, the pupils become true experts for developing secret writings in an appropriate state of the historical development of cryptographic concepts. Understanding the genesis of secure

communication schemes, they gain the motivation and the ability to improve “products” of science and technology because they think in terms of development processes. And all along the way, Papert’s ideas of *getting things to work* guide the progress.

Conclusion

Teaching with *Logo* philosophy is much more than a mere example of how to use digital technology in education. It is a didactic approach linking the educational concept of constructivism proposed by Jean Piaget with the concept of critical thinking. The approach pursues the goal to educate a new generation that does not believe facts without checking how they were derived. Similarly, products of technology are not just taken for granted, but the underlying construction process is analyzed.

In this overview, some of *Logo* philosophy’s key concepts that aim at achieving the abovementioned goals are discussed. Moreover, how to enrich these concepts while still strengthening the philosophy of constructivism and critical thinking is considered.

Technological Innovation

New technologies are appearing all the time in education. Some are adopted and used in the form in which they were offered; in some cases only certain aspects of the technology are adopted, while in others the technology is rejected entirely. This problem with innovation adoption is true of all new ideas or technologies. The process of innovation involves getting new ideas accepted or new technologies adopted and used (Tatnall

2011). After the discovery of a new idea or the invention and development of a new technology, it does not automatically follow that this will be adopted by its potential users.

It is important now to distinguish between invention and innovation. While invention involves the discovery or creation of new ideas or technologies, innovation is the process of putting these ideas or technologies into commercial or organizational practice (Maguire et al. 1994). The Oxford dictionary defines *innovation* as “the alteration of what is established; something newly introduced” (Oxford 1973) and is concerned with individual and business decisions to adopt new inventions. The study of innovation does not concern itself with inventors and the details of their inventions but about individual and organizational decisions to adopt these new inventions. Invention does not necessarily invoke innovation, nor is invention necessary or sufficient for innovation to occur (Tatnall 2011).

Making any change to the way things are done is a complex undertaking and difficult to achieve successfully. The success of any innovation is always in doubt because people who are prepared to support the innovator can be difficult to find and to convince. Although writing of *political* change over 500 years ago, Niccolò Machiavelli summed this up as follows:

There is nothing more difficult to handle, more doubtful of success and more dangerous to carry through than initiating changes . . . The innovator makes enemies of all those who prospered under the old order, and only lukewarm support is forthcoming from those who would prosper under the new. Their support is lukewarm partly from fear of their adversaries, who have the existing laws on their side, and partly because men are generally incredulous, never really trusting new things unless they have tested them by experience. (Machiavelli 1515)

Models of Technological Innovation

One of the difficulties faced in investigating the adoption of technological innovations is that not all of these innovations are adopted in the form in which they were proposed – not all are adopted without change. This raises the question of just

what was adopted in each case if it was in some way different from what was proposed by its instigator. To investigate this question, it is useful to make use of one of the theories of technological innovation: the theory of reasoned action, the theory of planned behavior, diffusion of innovations, the technology acceptance model, and the unified theory of acceptance and use of technology or innovation translation. This article will concentrate on the advantages of an innovation translation approach.

Early Theories of Technological Innovation

The theory of reasoned action (TRA) (Fishbein and Ajzen 1975; Ajzen and Fishbein 1980) integrated various studies on attitude from social psychology and postulated that an individual's behavioral intention is the immediate determinant of behavior, while their attitude and subjective norm are mediated through behavioral intention, and their behavioral and normative beliefs are mediated through attitude and subjective norm.

In the theory of planned behavior (TPB), Ajzen (1991) extended the TRA by arguing that some behavior that is not under a person's volitional control might be problematic due to the differences in individuals' abilities and in external forces. The modification involved adding another construct called perceived behavioral control required to perform the specific behavior.

Technology Acceptance Model (TAM)

TAM was developed Davis and others (Davis 1989; Davis et al. 1989) for predicting and explaining adoption and use of technology. It focuses on two theoretical constructs: *perceived usefulness* and *perceived ease of use*. Davis (1986) identified major determinants of technology acceptance and, beginning with the theory of reasoned action, specified a basis for causal links between the technology's *perceived usefulness* and *perceived ease of use* along with the individual's *attitude toward using technology* and *behavioral intention* to explain technology adoption (Davis 1986, 1989).

TAM theorizes that the effects of external variables (such as system characteristics, development processes, or training) on intention to use

the technology are mediated by perceived usefulness and perceived ease of use. TAM also has strong behavioral elements and assumes that a computer user normally acts rationally and uses information in a systematic manner to decide whether or not to adopt this particular technology in the workplace. It assumes that when someone forms an *intention* to act, they will be free to act without limitation. Perceived usefulness is also influenced by perceived ease of use because if other things are equal, the easier the system (technology) is, the more useful it can be (Venkatesh and Davis 2000). TAM assumes that usage of a particular technology is voluntary (Davis 1989) and that given sufficient time and knowledge about a particular behavioral activity, an individual's stated preference to perform the activity, their behavioral intention, will closely resemble the way they do behave (Tatnall 2011).

Unified Theory of Acceptance and Use of Technology (UTAUT)

UTAUT (Venkatesh et al. 2003) was developed to provide a refined view of how the determinants of intention and behavior evolve over time in explaining IT usage behavior. UTAUT has four core determinants of intention and usage: *performance expectancy*, *effort expectancy*, *social influence*, and *facilitating conditions* to predict behavioral intention and usage behavior.

Performance expectancy, effort expectancy, and social influence are proposed to be direct determinants of usage intention, while facilitating conditions is a direct determinant of user behavior. The key moderators posited to moderate this are gender, age, voluntariness, and experience.

UTAUT was developed from the theory of reasoned action, the technology acceptance model, motivational model, the theory of planned behavior, a combined theory of planned behavior/technology acceptance model, model of personal computer use, diffusion of innovations theory, and social cognitive theory (Venkatesh et al. 2003).

Diffusion of Innovations

Diffusion of innovations (Rogers 1995, 2003) is described as: "... the process by which an innovation is communicated through certain channels

over time among the members of social systems” (Rogers 1995: 5), and so a decision not to adopt an innovation relates to the rejection of the new idea. Rogers considers the four main elements of innovation to be *characteristics of the innovation*, *the communication channels*, *the passage of time*, and *the social system*. To explain the rate of adoption of innovations, Rogers suggests consideration of the following perceived characteristics of innovations: *relative advantage* (how is technology better than one it might replace?), *compatibility* (how different is this technology to one it might replace?), *complexity* (is this new technology complex and so difficult to use?), *trialability* (can a potential user trial the new technology before adoption?), and *observability* (will a potential user be able to observe other people making use of this technology?) (Tatnall 2011). It is based on the notion that adoption of an innovation involves the spontaneous or planned spread of new *ideas*. Rogers defines an innovation as: “. . . an idea, practice, or object that is perceived as new” (Rogers 1995: 11).

Rogers considers the four main elements of innovation to be *characteristics of the innovation*, *the communication channels*, *the passage of time*, and *the social system*. To explain the rate of adoption of innovations, Rogers argues that the attributes and characteristics of the innovation itself are important in determining the manner of its diffusion and the rate of its adoption.

Innovation Translation

The view of innovation proposed by actor-network theory (ANT), sometimes known as sociology of translations (Callon 1986b; Latour 1986, 1996; Law 1987), considers the world to be full of hybrid entities containing both human and non-human elements and offers the notion of heterogeneity to help in the explanation of technology adoption (Tatnall and Davey 2003). More specifically though, innovation translation (Callon 1986b; Latour 1996), informed by ANT, makes use of a model of technological innovation which uses these ideas, along with the concept that innovations are often not adopted in their entirety but only after *translation* into a form that is more appropriate for use by the potential adopter.

Callon (1986b) proposes that translation involves all the strategies through which an actor identifies other actors and arranges them in relation to each other, while Latour (1996) speaks of how “chains of translation” can transform a global problem, such as the transportation needs of a city like Paris (or the design of a new information system) into a local problem like continuous transportation (or using Visual Basic to obtain data from an Oracle database).

Latour (1986) maintains that in an innovation translation model, the movement of an innovation through time and space is in the hands of people, each of whom may react to it in different ways: they may modify it, deflect it, betray it, add to it, appropriate it, or let it drop. He adds that this is true for the spread of anything from goods and artifacts to claims and ideas and that the adoption of an innovation comes as a consequence of the actions of everyone in the chain of actors who has anything to do with it. He suggests that each of these actors shapes the innovation to their own ends, but if no one takes up the innovation, then its movement simply stops. Here, instead of a process of transmission, we have a process of continuous transformation (Latour 1996) where faithful acceptance involving no changes is a rarity requiring explanation. “Instead of the transmission of the same token – simply deflected or slowed down by friction – you get . . . the continuous transformation of the token” (Latour 1986: 286). McMaster et al. (1997) note that innovations do not wait passively to be discovered but that each actor translates and contributes its own resources to the final result (Tatnall 2011). A translation model requires the focus to be on understanding how actor-networks are created, strengthened, and weakened, rather than on cause and effect (McMaster et al. 1997).

Latour (1996) suggests that with the translation model, the initial idea hardly counts, and the innovation is not endowed with autonomous power or “propelled by a brilliant inventor” but moves only if it interests one group of actors or another. Movement of the innovation is a consequence of energy given to it by everyone in the chain, and when the innovation does interest a new group, they transform it a little or perhaps a lot. Latour

notes that, except in rare cases, there can be “no transportation without transformation” and that “...after many recruitments, displacements and transformations, the project, having become real, then manifests, perhaps, the characteristics of perfection, profitability, beauty, and efficiency that the diffusion model located in the starting point” (Latour 1996: 119).

Longenecker et al. (1994) suggest that computer-based information systems should be regarded as complex socio-technical entities, begging the question of how this complexity should be handled. A common method of handling complexity in all subject areas lies in simplification, but the danger with simplification is that it runs the risk of removing just those things that constitute a useful description of the phenomenon under investigation by concealing the parts played by many of the actors (Suchman 1987). The question here is which details to include and which to leave out and who is to decide. In this respect, an appropriate research approach needs to ensure that complexities are not lost “in the process of labelling” (Law 1991).

In actor-network theory, the extent of a network is determined by actors that are able to make their presence *individually felt* (Law 1987) by other actors. The definition of an actor requires this and means that, in practice, actors limit their associations to affect only a relatively small number of entities whose attributes are well defined within the network. An actor is not just a “point object” but an association of heterogeneous elements themselves constituting a network. An actor can, however, in many ways also be considered as a “black box” (Callon 1986a), and when we open the lid of the box to look inside, it will be seen to constitute a whole network of other, perhaps complex, associations. In many cases details of what constitutes an actor – details of its network – are a complication we can avoid having to deal with all the time.

Supposing that some person or group has developed a new technology and wishes to get it adopted. Actor-network theory asserts that the contributions of both humans and nonhumans (technology in this case) need to be given equal consideration, so this person or group proposing

the new technology is referred to by the term heterogeneous engineer. In explaining how this process works, Callon (1986b) outlines four aspects or “moments” in the process of translation:

1. *Problematization* involves the heterogeneous engineer defining the nature of the problem so as to be seen by other actors as having the answer.
2. *Interessement* involves interesting and attracting an entity by coming between it and some other opposing entity.
3. *Enrolment* occurs through a process of “coercion, seduction, or consent” and, if all goes well, leads to the establishment of a solid, stable network of alliances.
4. *Mobilization* locks in as the solution proposed by the heterogeneous engineer gains wider acceptance through some actors working to convince others.

Essentialist Approaches to Innovation Theory

Most of these approaches to technological innovation (TRA, TPB, TAM, UTAUT, and innovation diffusion but not innovation translation) suggest that some essential capacity or “essence” (Latour 1986) is largely responsible for determining its rate of adoption. A significant problem with an essentialist paradigm like this arises if a researcher tries to reconcile the views of all parties involved in the innovation on what particular essences constitute any given actor. The difficulty is that people often see different “essential attributes” in any specific technological or human entity, and this makes it difficult for a researcher to identify and settle on the ones that allegedly were responsible for the adoption (Tatnall 2011). Consider the case of two users of a mobile phone: a builder and a teenage girl. What essential characteristic would each see in the phone? The teenage girl would typically want a small, light phone that would easily fit into her handbag or pocket. She may favor a color like pink or blue. Her main use for the phone would be sending text

messages, speaking with her friends, or looking at her Facebook account. The builder, on the other hand, may want a phone that would clip onto his belt and would certainly not want one that was pink colored. His main use for the phone would be checking on deliveries of building materials and making appointments for future jobs. One could question whether they have adopted the same thing, but of course other aspects of the phone are common. They just do not agree on its essential attributes.

As an illustration of this point, Bigum (1998) contends that the assignment of intrinsic properties to technology, and in particular to computers in an educational setting, has the effect of allocating specific roles to the people and institutions that use them. Building on an argument propounded by Grint and Woolgar (1997), he contends that essentialist accounts which distinguish between human and nonhuman elements are forced to treat the machine as something with a set of fixed, intrinsic properties and the human elements as a context within which the technology is used. The problem, he points out, is that there does not appear to be a *single* essence of computers in education upon which everyone can agree. Some educators see the computer as embodying the “future of learning technology,” some as a pointer toward “anti-schooler” discourses; others see it in terms of concerns about the deployment of technology in Western society and still others in the negative light of all that is bad about dependence on technology. Any attempt at an essentialist approach, Bigum claims, would have trouble explaining how the “essential characteristics” of a computer could be seen quite differently by these different groups. He argues instead for an anti-essentialist approach based on innovation translation from actor-network theory in which, rather than containing essences, both human and nonhuman entities constitute roles for each other and work toward the establishment of durable assemblages. Such an approach, while still allowing the technology to negotiate a role, removes the necessity to make the concession of accepting some innate property within the technology that determines its fate (Tatnall 2011).

Use of Innovation Translation to Explain Educational Adoption

The remainder of this article will concentrate on innovation translation and its use to explain adoption, partial adoption, or non-adoption of new technologies in education.

Schoolchildren Who Have Learning Disabilities

Around the world there are a significant number of school students with learning disabilities (otherwise known as special needs) who require some assistance and support in their learning. The use of ICT and the Internet has played a major role in enhancing and shaping the knowledge, skills, and self-esteem of these students (Adam 2011). The study described here involved case studies and participant observation in two outer suburban special schools in Melbourne, Australia, and also looked at the role and impact of Victorian Education Department policies on these school environments (Adam and Tatnall 2010).

Special schools are especially complex socio-technical entities and research into their infrastructure, organization, and curriculum needs to take account of this complexity. A significant difficulty arises in framing research in a situation like this that involves both technological and human actors ranging from students and teachers to software and broadband connections. When dealing with the related contributions of both human and nonhuman actors, actor-network theory (Callon 1986b; Law and Callon 1992; Latour 1996) provides a useful framework. ANT reacts against the idea that characteristics of humans and social organizations exist which distinguish human actions from the inanimate behavior of technological and natural objects, instead offering a socio-technical approach in which neither social nor technical positions are privileged.

The actors involved in the adoption of this technology to assist students with special needs were found to include the students themselves, their parents, their teachers, school principals, school ICT specialist teachers, the school council, the web, microcomputers (PC and Macintosh), software, education department policies, learning technology policy, the school

environment, classroom environments, learning approaches and paradigms, delivery methods of instruction, engagement methods, thinking processes, technology infrastructure-bandwidth, curriculum, Internet resources, digital libraries, and other related special schools. A major challenge to schools of this type is to get all these actors to form a common problematization (Callon 1986b) of their task – to all see the problem in the same way. If this can be achieved, then all the actors can work together to achieve a common goal, and ANT offers some ideas on how this might be achieved.

Special School-A is a purpose built “specialist School” providing a range of educational programs for students with special learning needs including global development delay, autism spectrum disorder, and physical, social, and emotional disabilities (Adam and Tatnall 2010). A research project over several years investigated the infrastructure to set up links between different classes at the local level. The students showed a tremendous level of enthusiasm and immediate engagement when they began to communicate via the webcams. After a good start, however, this school made less use of ICT after the school principal left.

Special School-B has a vision that encompasses a commitment to achieving excellence in education for students with additional learning needs through a curriculum which integrates learning technologies with best practice in teaching and learning (Adam and Tatnall 2010). Located on two campuses in the northern suburbs of Melbourne, School-B is a day specialist school which caters for students with mild to moderate intellectual disability between the ages of 5 and 18 years. As part of its facilities, the school is well-equipped with a Technology Center that caters for students 16–18 years of age with a focus on the development of dual pathways to cater for the diverse needs of these students. In 2006 it introduced a number of social and networked learning activities and practices with software such as Lumil, WordPressMU, ccHost, Urdit, Gregarius, and Scuttle. The school has a high level of commitment to a curriculum which integrates learning technologies with best practice

in teaching and learning in order to enhance educational outcomes for its students.

Why was School-B, in particular, successful in adopting ICT? The answer can be found in examining the actors and their interactions. Firstly the school principal (B), who was very enthusiastic about the possibilities of using ICT, developed a problematization in which his students would make educational gains. He then made use of his skill in *interessement* to convince his teachers and parents of the value of this approach and so quickly achieved enrolment. Further to this, the principal, teachers, and parents became mobilized to tell others of what the school had achieved.

Entry of Visual Basic into a University Information Systems Curriculum

In the early 1990s, Wills Institute of Technology (WIT) was located in the suburbs of Melbourne. In the early 1990s, Fred (These are not their real names) was teaching COBOL on VAX minicomputer and Pascal in MS-DOS on PCs (Tatnall 2007) but discovered that the students found that writing a program in either of these languages was quite hard going. Fred had discovered Visual Basic (VB) for MS-DOS when undertaking a programming job for a small garage. He found that he instantly liked the way that VB allowed the programmer to get to a good looking prototype solution very quickly and with much less bother than other approaches.

One of the subjects Fred had just started teaching at WIT at the time was an introductory information systems subject that required the use of a screen prototyping tool in one topic. After his recent experience with VB, Fred wondered whether some aspects of the MS-DOS version of VB could do the job. He was not interested in the programming features of VB in this, just those using its screen design. Fred could only use VB in this way by *translating* (Callon 1986b) it from a “programming language and visual programming environment” into a “screen prototyping tool,” which he did by selecting some features of VB while ignoring others (Tatnall and Davey 2001).

As the student labs had by now been equipped with new PCs with Microsoft

Windows, after this successful curriculum innovation, Fred decided to give the Windows version of VB a try in an operating systems programming subject. This subject had previously concentrated on programming within a Unix environment on the VAX, but with the growing importance of the PC and Microsoft Windows at this time, Fred thought he could well justify making use of VB to write operating system extensions for Windows instead of Unix. This involved another translation of VB to become a “language to teach operating systems programming.” This was achieved by leaving out all of VB’s visual aspects and concentrating on just those aspects of VB that related to operating systems extensions for Windows. All this would, of course, not have been possible if it had not been for the formation of a viable and cooperative VB network consisting of Fred, the introductory IS subject, the operating systems programming subject, Visual Basic, the student labs, and the students. All of these actors needed to work together cooperatively to make the adoption of VB a success.

A couple of years later, Wills Institute then merged with Burke Institute (BIT) to form Burke University of Technology. In the revised information systems curriculum of the new university, a decision was needed in choosing a programming language for a third year programming unit. It was thought that this language should address issues such as graphical user interface, client-server concepts, and possibly multiple platforms. With a little help from Fred, Visual Basic was the language chosen for this subject with another translation of VB to become “Visual Basic the language for rapid application development with databases.” The main aim of the subject was to show students how a programming language, Visual Basic in this case, could use SQL commands to interact with a database management system. After the experience of Fred’s screen prototyping subject had shown students and many of the academic staff some of the ways in which it could be used, VB was easily able to enrol many of them as allies in its attempt to become the language of choice for this subject.

Adoption of Mobile E-Training in a Factory

A large factory is keen to ensure that its workers are well trained to safely use all its new machinery and equips each employee with a tablet PC fitted with wireless networking containing delivery software and a profiling program for the particular employee. Each factory machine has its own operating procedures, and details of safety considerations are stored in the machine. As an employee moves through the factory to use different machines, this safety information is made available through wireless networking. Software on the machine recognizes the tablet PC of a new operator and automatically downloads content to this computer which configures it to what it has determined to be the learning style of the employee (Tatnall and Davey 2003). Although factory management issues each employee with their own tablet PC, encouraging or forcing them to use it is another matter. What factors determine the likelihood or adoption of this innovation?

With an actor-network analysis, the researcher would first identify as many as possible of the (human and nonhuman) actors. In this case some of these actors are obvious: factory employees, management, factory machines, learning packages, tablet PC, wireless networking, delivery software, and the profiling program. The way to proceed now is to interview the actors. While it might seem odd to speak of “interviewing” the nonhumans, this is done by looking at instruction manuals, speaking to various humans about them, investigating how, and why, they were built, and any other techniques that simulate an interview situation. We then proceed to “follow the actors” (Latour 1996) in determining what is important and what is not with the aim to discover networks of associations and interactions.

If the employer-employee relationship in this company is such that the workers are suspicious of any initiative coming from management, then this is likely to be significant. At this stage we attempt not to judge the likely consequences to potential adoption, just to note this interaction. Most of the other interactions are between the factory workers and various nonhuman actors. In common with an approach using innovation diffusion, we would

investigate how they use the machines; is this simple and straightforward, or is it difficult and clumsy? What about the interactions with each of the computer-based technologies? How does the employee interact with the learning package? Do they like using the tablet PC? Do they find carrying it around a nuisance? How does management view these technologies? Do they have any interactions with them? How did they decide on the learning package? Why did they decide to use mobile technologies rather than a training room? One difference between these approaches to theorizing innovation is that innovation diffusion concentrates more of the characteristics of the technology and TAM and UTAUT look at its perceived usefulness and ease of use, while innovation translation tries to look beyond this to investigate the human and nonhuman interactions involved.

The Victorian Education Ultranet

In Australia and many other countries, parents have traditionally been informed of their children's progress at school through the use of school reports, parent-teacher evenings, and an annual "Open Day." All parents want to know both what their children are doing at school and how well they are progressing. They want to know as much about the school, where their children spend so much time, as possible. In 2010 the Victorian Government introduced an online system, the Ultranet, for informing school communities by use of web-based technology (Tatnall and Dakich 2011). It was designed to support knowledge sharing across Victorian government schools and also to provide facilities for informing parents and for curriculum delivery and online learning and teaching (Department of Education and Early Childhood Development 2010a). The Victorian Government's Department of Education and Early Childhood Development (DEECD) described the Ultranet as "a student centred electronic learning environment that supports high quality learning and teaching, connects students, teachers and parents and enables efficient knowledge transfer" (Department of Education and Early Childhood Development 2011). The Ultranet was essentially an extended intranet/

extranet and was rolled out to all government schools in September 2010 (Tatnall and Dakich 2011). After a short and not very successful life, it was finally abandoned in June 2013.

Study of adoption of the Ultranet required looking at the contributions and interactions of human actors but also of those of nonhuman actors including the technology itself. It is important to think of the Ultranet as an actor and not just an artifact. The following human actors can be identified: state government policymakers, students (over 500,000), teachers (about 40,000), parents (about 1 million), principals of government schools (about 1,500), school councils, teacher educators, pre-service teachers, and the Ultranet developers. There are also many non-human actors: broadband connections, Web 2.0 technologies, schools, school computers, home computers, the Victorian Institute of Teaching and Learning, the emerging national curriculum, policies, privacy laws, DEECD, the Victorian Government, and the technology of the Ultranet itself (Tatnall and Dakich 2011; Tatnall et al. 2011). It is, however, not the actors themselves that are important but their interactions with each other (Fig. 1).

The problematization of the Ultranet by the government was as a system to offer access to learning materials and to inform parents of their child's progress. This seemed worthwhile to many when it was first proposed. Unfortunately not enough effort was then put into convincing teachers and parents to accept this problematization and so to become enroled. The Ultranet was officially launched in August 2010 when Victoria's 1,500 state schools were closed for an extraordinary student-free day for teacher professional development (Department of Education and Early Childhood Development 2010b). All 3,500 state school principals and assistant principals were called to Melbourne to attend Ultranet's "Big Day Out" at the Melbourne Exhibition and Convention Centre to learn about the state's new online learning network. Teachers across the state were asked to familiarize themselves with the Ultranet from their own school location, but unfortunately the launch turned into a fiasco when the Ultranet crashed disastrously

Technological Innovation in ICT for Education, Fig. 1 Ultranet – the big idea

at 9 am (Tatnall et al. 2013). The first attempt to convince teachers of the value of the Ultranet at the “Big Day Out” and student-free day for professional development was thus a failure. This attempted intersement was a disaster that, far from convincing teachers of the Ultranet’s worth, did exactly the opposite. Another attempt at intersement was in appointment of Ultranet coaches for schools, but unfortunately some coaches did not seem to understand the human issues involved in convincing teachers and parents to use the Ultranet. One coach told a school that it just had to use the Ultranet as it was DEECD policy, with no other justification. In another failure of intersement, a parent of

secondary schoolchildren pointed out that he had not been able to find out much about the Ultranet and that as far as he was aware his children’s school was not using it. Clearly there should have been a good deal more done to convince principals, teachers, and parents of the Ultranet’s value. The human aspect of promoting the Ultranet was not given sufficient consideration.

School Management Software: MySchool and CASES21

The adoption and use of school management software require a socio-technical approach as there is a need to consider both the human actors such as teachers, parents, and students and also various

nonhuman actors including school computers, administrative software, and the Internet. Administrative computer systems in schools have been designed to meet the need to handle the large amount of data relating to individual students and student groups (Davey and Tatnall 2012). In terms of ANT, however, users have no input into use of these systems with only the choice of using them in their current form, or not. There has been no possibility of translation.

A website designed by the Australian Commonwealth Government to inform parents and the community about all Australian schools is **MySchool**. Early in 2010 the Australian Government launched this e-government initiative (Gillard 2010) that contains information about all of Australia's 10,000 primary and secondary schools. The aim was to allow parents to compare schools to which they might potentially want to send their children or to see how their child's school compares with other local schools. It includes information on the number of students and teachers at the school, the socioeconomic background of the parents, and an indication of how the school is performing in national literacy and numeracy testing (Davey and Tatnall 2012). It provides information so that parents can compare their school (or potential school) with neighboring schools and with 60 statistically similar schools (Gillard 2010).

The human actors involved in the adoption of MySchool include teachers, school principals, and parents. The main nonhuman actors are schools, school computers, home computers, national curriculum policies, privacy laws, and the technology of the MySchool website. There has been no compulsion for schools, teachers of parents to adopt MySchool and also no possibility of its translation into a different form.

The MySchool website was initially seen to threaten the relationship between parents and schools by providing easy access to information about all schools and the possibility of a "league table" of the "best" schools in the country. Teachers and school principals have a profound interest in the MySchool website as potentially it could affect the number of new students wanting to attend their school and to the retention of

current students. One possible consequence of MySchool was that parents may have considered moving their children to another school if their current school's performance was below par. MySchool developers similarly recognized the power of teachers at the local level and so completely bypassed them, communicating through the public website rather than through normal school communication channels, all of which required teacher involvement. There has been a good deal of controversy about MySchool as some schools consider that they have been unfairly treated and that as a consequence they have lost potential students. Others have argued that the methodology for obtaining and showing the data is flawed.

CASES21 (Computerized Administrative Systems Environment in Schools) was built to provide a clear single means of gathering the data required by government from schools. In the past, in a large centralized system such as the Victorian Education Department, keeping track of what schools were *really* doing was very difficult. In particular getting consistent financial data from schools when they each had their own accounting system was almost impossible (Birse 1994). This is why an early version of CASES was initially introduced in the mid-1980s and mandated for use in all Victorian government schools. The prime purpose of the latest version, CASES21, is to enable reporting from schools back to the Department of Education, rather than to directly assist schools with their own administration (Birse 1994; Tatnall 1995). CASES was developed as a tool for overall school administration and as a means whereby schools reported back to the Department of Education (Tatnall 1995).

Here the human actors include teachers, school principals, school administrators, teacher educators, and the CASES21 developers. The nonhuman actors include broadband connections, Web 2.0 technologies, schools, school computers, policies, privacy laws, school councils, the Victorian Department of Education and Early Childhood Development, the Victorian Government, and the technology of CASES21.

Most teachers, except those in administrative positions, have little direct interaction with CASES21 other than making use of its output. They do not tend to make suggestions for improvement (translation) to CASES21 as they think that these will not be given serious consideration. CASES21 has an impact on parents to the extent that the system provides them with fast access to important information (from the Education Department) through a single system, but they only have access to its output in the form of lists and reports. School bursars and other administrative staff make considerable use of CASES21. It has had a large effect on how they perform their work, but as it is a closed system, they are not able to have any effect on it. There is no possibility of translation.

One Result of Project Management Training

IT organizations and organizations with IT Departments frequently procure project management training as part of their initiatives to improve business outcomes through professional education (Lecomber and Tatnall 2014). As project management has evolved as a field of practice, organizations have realized that their entire business, including most of the routine activities, can be regarded as a series of projects. The Business Directory (2017) defines a project as a: “Planned set of interrelated tasks to be executed over a fixed period and within certain cost and other limitations.” Simply stated, all organizations are managed by using projects (Kerzner 2014), and this is even more so in the development of information systems. Since the Australian Computer Society included IT Project Management in its Body of Knowledge for Computer Professionals (Tatnall and Reyes 2005), most Australian universities now include one of more IT Project Management subjects in both undergraduate and postgraduate degrees. In most cases this involves practical work using case studies and software packages such as Microsoft Project to formalize these concepts. As well as IT Project Management education in universities however, there is also substantial industry professional training in project management.

A research study was conducted by Lecomber (2017) to understand how participants used and adopted the PRINCE2 methodology for workplace projects following a professional training course. Projects in Controlled Environments version 2 (PRINCE2) is a methodology for managing projects and has grown to become a de facto “standard” as a project management method in more than 150 countries worldwide (Sargeant et al. 2010; AXELOS 2015). The PRINCE2 methodology was developed for the UK Government to manage their IT projects and was based on soft systems methodology (Checkland and Scholes 1991; Finegan 1994; Sargeant et al. 2010; AXELOS 2015).

The study workplace consisted of a number of departments, one of which was an IT department. IT staff participated in the professional training program which consisted of staff drawn from the various departments across the organization. The results showed that there were some participants who adopted as much of the PRINCE2 methodology as they were able for their work projects and actively sought to improve their practice. Another group of participants had knowledge of the methodology but considered the overhead in using it far outweighed the benefits derived from this. To analyze these two different forms of adoption, innovation translation, informed by actor-network theory, was used. Innovation translation has the advantage of being able to explain examples of partial adoption and of situations where what is actually adopted differs from what was proposed (Tatnall 2009). This was particularly relevant for this study as it could be said that one group of participants made *only* a partial adoption.

Some of the participants adopted as much of the PRINCE2 methodology as they were able for their projects and actively sought to improve practice. The study named this adoption as the Performing Translation (**PT**). Those who had adopted **PT** had a focus on continuous improvement in their practice. They are people who keep attempting to apply their learning and hence learn more. In addition, those who adopted the **PT** conducted their own research into “best practice” outside of work hours.

The other group of participants who had knowledge of the methodology but considered the overhead in using it far outweighed the benefit derived from doing so formed the Knowing Translation (**KT**). A **KT** sees nothing in the formal structures of PRINCE2 that is so valuable that they would sacrifice early delivery by going through procedures stated in the methodology. Those who had adopted the **KT** would only apply what they had learned to the workplace if they perceived adoption across the organization.

In the case of **PT** participants, as their organization did not have supports such as strong leadership for using a methodology and a strong project management office (PMO), some participants who adopted the **PT** eventually resigned from the organization. In this research study, the PMO was weak and could not enforce the governance needed to support the use of PRINCE2. Participants whose form of adoption was the Knowing Translation (**KT**) had knowledge of the project management methodology but considered the overhead in using it too great. The lack of support from the top-down commencing with the senior leadership team and the original sponsor of the methodology had a strong influence on those who adopted the **KT**. A senior leadership team and sponsor must go beyond paying lip service to the methodology and actively comply with the methodology in terms of behaviors, responsibilities, and expectations of their role on the project as sponsors and project board members.

In this study, the emergence of these two possible adoption outcomes – these two translations – has implications on how organizations derive value from their investment in professional project management education and training. As well as ensuring that the project management training is performed well, it is important that organizations commit to supports in place such as a strong PMO, senior leadership support, and strong visible support from the sponsor if the organization wishes to derive value from the project management training. Otherwise the investment in training is a waste of money. This is particularly important in the education of IT professionals.

Conclusion

This article has described a number of approaches to theorizing technological innovation in various forms of education and training. It has illustrated some of the significant advantages of using an innovation translation approach to the theorizing of innovation adoptions in education. Despite this, however, it is far too simplistic to suggest that innovation translation offers a better approach than innovation diffusion, TAM, or UTAUT to theorizing innovation in *all* situations. Many studies have shown the explanatory value of innovation diffusion, particularly in relation to large-scale adoptions such as (to offer some samples from Rogers (1995)) bottle-feeding of babies in the third world, the diffusion of modern maths in Pittsburgh, diffusion of the news, and the diffusion of a medical drug.

It might be suggested that the relationship between these types of approach, innovation diffusion on the one hand and innovation translation on the other, has something in common to that between the macro- and microelements of Newtonian and quantum mechanics in physics. While quantum mechanics is needed to explain what goes on when fundamental particles and atoms interact, for everyday occurrences Newtonian mechanics is quite suitable. Likewise I would suggest that while actor-network theory and innovation translation better explain the detail of how individuals and specific organizations adopt technological innovations, innovation diffusion does a good job in explaining large-scale adoptions.

Introduction

The use of (digital) technologies in mathematics and in mathematics education is related but not the same. Already in ancient times, people used “machines” like the abacus or the soroban to support doing calculations. And, from the seventeenth century onward, the inventions of mechanical calculation machines and electronic calculators or the use of computers or smartphones aimed at sparing people the tedious trouble of calculating in mathematics.

Obviously, in mathematics education, where acquiring calculation skills is still an important objective, each of these inventions sets of a discussion on the admittance of the device in mathematics classrooms (i.e., Waits and Demana 2000; Herget et al. 2000). Now, there is more or less an understanding that the use of technology in mathematics classrooms depends on the situation. Only what is an appropriate use for a given situation is still and will always be a topic discussed among mathematics teachers, educators, and education researchers. There are countless projects and research papers on more or less successful

uses of technology in mathematics learning. In meta-studies, Hattie (2008) or Tamim et al. (2011) describe only low impacts of the use of technology on learning outcomes and even specifically for mathematics education. Li and Ma (2010) find only small positive effects of technology on mathematics achievement (p. 225). There seems to be some relationships between the use of technology, the mathematical achievement, and the teaching approaches. The more the teachers/schools tend to constructivism, the higher the impact of the technology (Li and Ma 2010, p. 228). So, to understand the appropriate use of technology in mathematics education, both the technological tools and the pedagogical approaches to mathematics teaching and learning have to be considered.

The Executive Summary of the NCTM “Principles and Standards for School Mathematics” states the role of technology in mathematics learning very well:

Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students’ learning. Students can develop deeper understanding of mathematics with the appropriate use of technology. Technology can help support investigation by students in every area of mathematics and allow them to focus on decision-making, reflection, reasoning, and problem-solving. The existence, versatility, and power of technology make it possible and necessary to reexamine what mathematics students should learn as well as how they can best learn it. (NCTM 2000b, p. 3)

The use of technology in mathematics education should always aim at fostering the understanding of mathematics and allow students to “do mathematics” and not only save them from doing calculations. Therefore, the aspects of good mathematics teaching and helping students understand mathematics, always in relation to the use of technology, will be discussed in the next entry. Descriptions of the different technological tool types and their potential for learning mathematics will follow.

Pedagogical Aspects of Mathematics Learning

All over the world, the mathematical content usually taught in schools is rather similar. The topics

covered in mathematics classrooms are typically arithmetics, measurement, geometry, algebra, calculus, linear algebra, data analysis, statistics, and probability.

For all of these topics, there are software tools covering more or less the content taught in schools. So, if the objectives of mathematics education would just be calculation and geometrical construction skills, nobody would still need to learn mathematics, because the technological tools will always be faster and better. But mathematical understanding based on mathematical knowledge and mathematical processes is considered necessary for every educated person. Mathematical competencies allow a person to solve problems using mathematical methods. An important part of mathematical competency is the knowledge when and what type of mathematical technology to use for solving the problem.

At the beginning of the century, “mathematical processes” or “general mathematical competences” were introduced in mathematics curricula all over the world. One reason were the TIMSS (Third International Mathematics and Science Study) (<https://timssandpirls.bc.edu/>) and the PISA (Program for International Student Assessment) (<http://www.oecd.org/pisa/>) studies. Because the test items in both studies not only covered mathematical skills but also the application of mathematics to solve – previously unknown – problems and to use mathematical modeling to solve realistic problems. At the same time, the educational standards and curricula of many countries became available due to the dissemination through the World Wide Web. The mathematics education communities took up to describe mathematical processes, which all students should be able to perform.

There are different names and sometimes different categorizations of these mathematical processes, but from a broader point of view, they are surprisingly similar. A reason for this similarity might be that doing mathematics is very global and intercultural. So, for the purpose of this entry, the categorization of the National Council of Teachers of Mathematics (NCTM 2000a) is used. For each process, a typical example is given, where technology is used.

Problem-Solving

Problem-solving means much more than just working on a mathematical task. It refers mainly to solving problems where the student does not know the solution method beforehand. Therefore, the students need to think of new ways to apply their mathematical knowledge. This is much more demanding than just doing, for example, algorithmic calculations.

The NCTM defines the “Problem-Solving Standard” as to enable students to:

- build new mathematical knowledge through problem solving;
- solve problems that arise in mathematics and in other contexts;
- apply and adapt a variety of appropriate strategies to solve problems;
- monitor and reflect on the process of mathematical problem solving. (NCTM 2000a, p. 52)

Example: Calculation of compound interest

Compound interest means that you have a certain amount of money, which is placed at a bank. On this deposit the bank gives you some interest, i.e., 3% p.a. (per year). If you leave the deposit and the interest in your account, the amount increases exponentially. To answer questions regarding the time needed to accumulate a certain amount of money the typical mathematical solution would use a logarithmic expression. But this problem can also be solved using a spreadsheet.

Samantha wants to invest 5000 € at a bank where she gets 4% p.a. She won't need the money in the next years so she can leave the amount and the interest in the account. How long will it take to double the initial investment?

Figure 1 gives the solution of the problem using a spreadsheet.

As the input line shows, the calculation follows directly the given situation: Each year the previous amount is kept on, and the simple interest for the previous amount is added. After setting up the spreadsheet like this, you only have to pull down the lower right corner of the cell until the amount exceeds the 10,000€.

	A	B	C	D
1	Starting Amount		5,000.00 €	
2	after year	1	5,200.00 €	
3		2	5,408.00 €	
4	Interest Rate	3	5,624.32 €	
5	4.00%	4	5,849.29 €	
6		5	6,083.26 €	
7		6	6,326.60 €	
8		7	6,579.66 €	
9		8	6,842.85 €	
10		9	7,116.56 €	
11		10	7,401.22 €	
12		11	7,697.27 €	
13		12	8,005.16 €	
14		13	8,325.37 €	
15		14	8,658.38 €	
16		15	9,004.72 €	
17		16	9,364.91 €	
18		17	9,739.50 €	
19		18	10,129.08 €	
20		19	10,534.25 €	
21		20		
22		21		
23				

Technologies in Mathematics Education, Fig. 1 Example problem solving ‘compound interest’- solution using a spreadsheet

The answer in this case would be: *After 18 years the starting amount has doubled.*

Without technology the calculation would have to be done by hand, which would take too much time or using the logarithmic formula

$$K_n = K_0 \cdot \left(1 + \frac{p}{100}\right)^n \Rightarrow n = \frac{\log K_n - \log K_0}{\log \left(1 + \frac{p}{100}\right)}$$

which, for example, in Germany is not part of the high school curriculum anymore.

Reasoning and Proof

Reasoning and proof are the typical ways for mathematicians to find the truth of statements or more formally of theorems. Introducing this most immediate mathematical process in the school curriculum does not mean students have to grow into experts giving formal mathematical proofs. Reasoning and proof means here to explain why solutions are

correct or mathematical statements are true and on which conditions these solutions/statements are allowed. Considered from the other way, if school mathematics evades this process, how could they claim to do mathematics? If students never learn to ask for reasons why something is true or working and to appreciate mathematical reasoning and proof, their only source for mathematical truth or correctness would be the teacher and the textbook.

The NCTM defines the “Reasoning and Proof Standard” as to enable students to:

- recognize reasoning and proof as fundamental aspects of mathematics;
- make and investigate mathematical conjectures;
- develop and evaluate mathematical arguments and proofs;
- select and use various types of reasoning and methods of proof. (NCTM 2000a, p. 56)

Example: *Construct a triangle and connect the midpoints of the sides to form an inscribed triangle. What do you observe in regard to this inscribed triangle?*

Write down your conjectures. Explain why your conjectures are true.

Using a Dynamic Geometry Software (DGS), students construct the triangle and the mid-triangle using the “midpoint” feature (Fig. 2).

Some possible conjectures students might come up with are:

- The big triangle is split into four small triangles.
- The mid-triangle is similar to the big triangle.
- The area of the mid-triangle is the fourth part of the area of the big triangle.
- The four small triangles are congruent to each other.
- The construction is an application of the intercept theorem.

To explain why the conjectures are true, students could use the intercept theorem with the intersection point C of the two lines AC and BC. Because CF is half the length of CA and CE half the length of CB per construction and then because of the “reversed intercept theorem,” the lines FE and AB are parallel. Following the

Technologies in Mathematics Education, Fig. 2
Example reasoning and proof ‘mid-triangle’ - DGS configuration 1

intercept theorem, the length of the segment FE is half of the length of the segment AB. This holds for all sides of the mid-triangle. Therefore, the triangle DEF is similar to the triangle CAB.

The reasoning – or if put more formally even the proof – could be done in the same way just using paper and pencil.

The use of the DGS allows the students to observe what happens to some properties of the construction, if, i.e., the point C is moved and therefore the shape of the triangle changes. This helps to distinguish random phenomena from phenomena inherent to the mathematical situation.

Another possible state of the DGS construction shows Fig. 3.

In this case there is a right angle at the point A. This is definitely a very special case. But, in this specific state, it is quite obvious that the triangles ADF and EFD complement each other to a rectangle. Because of the common diagonal – and the rectangle properties – the two triangles must be congruent.

This could help some students to get the idea of checking on congruent or similar figures, which could set them on the way of sound mathematical reasoning.

Technologies in Mathematics Education, Fig. 3
Example reasoning and proof ‘mid-triangle’ - DGS configuration 2: special case

Communication

Communication is, contrary to common beliefs, a very important part of doing mathematics. So is a mathematical theorem only then proven, if it is published and the mathematical community approved the proof, which means they did not find any faults in the reasoning of the author – yet. For learning mathematics, the use of language (oral, written, symbolic, etc.) is even more important. Because mathematical constructs like a tangent, parallel lines or recurring decimals only exist in the mind. For students to understand these constructs, they have to build their own mental models. And for this communication is essential.

Since technology is often designed to enable communication and interaction in any fields, this is also true for mathematics education. Mathematical reasoning is in itself a form of communication.

The NCTM defines the “Communication Standard” as to enable students to:

- organize and consolidate their mathematical thinking through communication;
- communicate their mathematical thinking coherently and clearly to peers, teachers, and others;
- analyze and evaluate the mathematical thinking and strategies of others;
- use the language of mathematics to express mathematical ideas precisely. (NCTM 2000a, p. 60)

Example: *Write a computer program to calculate the greatest common divisor (GCD) of two numbers.*

Some possible programs in pseudocode are shown in Table 1.

Technologies in Mathematics Education, Table 1 Example communication ‘computer program to calculate the greatest common divisor’ (All examples are taken from https://en.wikipedia.org/wiki/Euclidean_algorithm, retrieved on 2017/10/01, 12.33. The original sources are Knuth (1997), p. 318ff (division and subtraction versions) and Stillwell (1997), p. 14 (recursive version).)

Division-based solution	<pre>function gcd(a,b) while b ≠ 0 t := b; b := a mod b; a := t; return a;</pre>
Subtraction-based solution	<pre>function gcd(a,b) while a ≠ b if a > b a := a - b; else b := b - a; return a;</pre>
Recursive solution	<pre>function gcd(a,b) if b = 0 return a; else return gcd(b, a mod b);</pre>

To write computer code in whatever computer language, the mathematical ideas behind the concepts have to be understood, and the programming requires to be very precise.

Connections

Mathematics is applied in many different contexts in our world. Without mathematics, neither our society nor the technology would work. Most people do not realize this fact but think mathematics is something done in school or used by engineers. So the application of mathematics in real life has to be addressed in mathematics classrooms. Another aspect is that based on everyday situations, mathematical models can be understood. A typical example is buying vegetables, which can give an idea about the mathematical concept of proportional functions: The more potatoes you buy, the more you have to pay.

Finally, mathematical fields (e.g., algebra and geometry) are connected to each other, and techniques or problem-solving strategies of one field can be applied in another. There are even specific software to support this connection like most Computer Algebra Systems that show diagrams and even dynamic geometry features and vice versa.

Realistic situations usually come with “uncomely” numbers, so technology is often needed to do the calculation.

The NCTM defines the “Connections Standard” as to enable students to:

- recognize and use connections among mathematical ideas;
- understand how mathematical ideas interconnect and build on one another to produce a coherent whole;
- recognize and apply mathematics in contexts outside of mathematics. (NCTM 2000a, p. 64)

Example: *Find the maximum of the function*
 $f(x) = x \cdot (1 - x) \cdot e^x$.

Using a Computer Algebra System (GeoGebra) yields this answer: (Fig. 4)

The connection between the algebraic expression and the graph is obvious. In a calculus

classroom, students might be able to find the maximum using paper and pencil, but the graph would be very difficult to draw precisely.

Representations

As seen in the above examples, mathematics can be represented in very different forms. The different representations of functions i.e., verbal, algebraic, numeric, and graphic are an important topic in school mathematics. Depending on the question, some forms are better for solving problems than others, and sometimes only a change from one representation to another helps.

The NCTM defines the “Representations Standard” as to enable students to:

- create and use representations to organize, record, and communicate mathematical ideas;
- select, apply, and translate among mathematical representations to solve problems;
- use representations to model and interpret physical, social, and mathematical phenomena. (NCTM 2000a, p. 67)

Example: *Find the line of best fit given the data.*

In mathematics classrooms, this question is usually answered using the “least squares method,” a standard approach in regression analysis. There are numerous programs and applets in the internet allowing students to solve this problem experimentally. One is part of the NCTM Illuminations (<http://illuminations.nctm.org/Activity.aspx?id=4186>) website (Table 2).

This is only a very short overview over mathematical processes in mathematics education where the use of technology opens up new possibilities. How acquiring each of the processes works as well as the use of technology supporting the development of the general mathematical competencies are intensely worked on research areas.

In mathematics education, the pedagogical aspects should be decided on first and after that only the question arises, whether to use technology at all and if yes, for what purpose exactly. The next section addresses the main types of technologies used in mathematics education.

Technologies in Mathematics Education, Fig. 4 Example connections - 'maximum of the function $f(x) = x \cdot (1 - x) \cdot e^x$ ' using a CAS

Specific Tools

The following section can only give a very superficial glance at the types of technological tools used in mathematics education. For one thing, there are new tools developed permanently, and on the other hand, nobody can know all the available tools. Since many of these tools are initiated or even developed by teachers or school-related projects, very often the tools are only available in the mother tongues of the developers and are not very well maintained. Another phenomenon is the coalescence of the different types of tools, i.e., the combination of Computer Algebra System, Dynamic Geometry Software, and spreadsheet functionality as in GeoGebra (<https://www.geogebra.org/>).

The (non-)mentioning of specific software or websites is not in any case an indicator of the quality of the software but due mainly to the personal history of the author. Usually educational research groups, ministries of education, and

organization involved in “good education” offer country-specific lists of available technological tools.

Virtual Manipulatives

In preschool and primary education, hands-on manipulatives are used to understand the number system and the basic operations like addition, subtraction, multiplication, and division. Later on, other manipulatives like geometrical solids or pattern blocks or construction tools (i.e., compasses or protractors) are introduced. Supplementary the use of virtual manipulatives often as apps on tablets is increasing. As with all manipulatives, their use in classrooms needs a teacher with a lot of expertise, because they are not self-explanatory and sometimes can lead to misconceptions. Figure 5 shows an example for base ten blocks, used in primary school when numbers up to 10,000 are introduced.

The advantages of virtual manipulatives are the fact that they do not get lost and that there are

Technologies in Mathematics Education, Table 2 Example representations ‘finding the line of best fit’ (Source: <http://illuminations.nctm.org/Activity.aspx?id=4186>)

Here the points are just added in the coordinate system. Measurement data resulting from an experiment can be added via the coordinates

The student then “guesses” the best fitting line by moving the two points which define the straight line

Then the line of best fit according to the regression analysis is shown. Students could now change their guess accordingly

(continued)

Technologies in Mathematics Education, Table 2 (continued)

More interesting would be the question which point of the given data has to be moved where to, to make the guess a better fit

Of course, you would need some experience with finding the line of best fit, to predict the necessary movement correctly. But this is exactly a situation where the three different representations facilitated by technology allow a deeper mathematical thinking than without

always enough of them available – if there are enough devices. The handling is mostly very easy and sometimes even better suited for small children than hands-on materials.

Some of the virtual manipulatives even allow feedback or manipulations, which are impossible in real life. An example of impossible building blocks (<http://www.fisme.science.uu.nl/toepassingen/28432/>) in geometry is shown in Fig. 6.

Spreadsheets

Spreadsheet software like Microsoft Excel or Openoffice Calc are not primarily meant for mathematics education; their main use is the presentation of numbers and the creation of diagrams. In mathematics classrooms, these tools can be used like in everyday life, i.e., for cost planning calculations or generating diagrams.

They can also be used for very simple worksheets giving automatic feedback using the “if function” shown in Fig. 7.

Due to the structure using cells, spreadsheets are a very well suited for discrete mathematics. Also, functional attributions using variables and even recursive equations can be used easily as shown in Fig. 1. Using the advanced features of

spreadsheets like a scroll bar, the Excel solver – optimization methods – or VBA programming spreadsheets can be extended to complex interactive learning environments. Nowadays even graphic calculators have some spreadsheet functionalities implemented, i.e., to create a table of values.

A non-free extension of spreadsheets is the software “Fathom” (<http://fathom.concord.org/>). Fathom is specialized to do data analysis and statistics adapted to the typical high school curriculum for statistics and mathematical modeling.

Dynamic Geometry Software (DGS)/ Interactive Geometry Software (IGS)/Dynamic Geometry Environments (DGEs)

Dynamic Geometry Software, developed in the late 1980s especially for geometry classrooms, was based originally on the geometry using only compass and straightedge (ruler). Meanwhile a lot of different features, e.g., measuring of lengths, angles, and areas, were added.

The main advantages compared to “normal” drawing software are:

Technologies in Mathematics Education, Fig. 5 Example of virtual manipulatives base ten blocks (Source: http://nlvm.usu.edu/en/nav/frames_asid_152_g_1_t_1.html?from=category_g_1_t_1.html)

- The ability to vary already generated constructions (“drag mode”)
- The possibility to create loci if constructed points are varied using the tracing mode (“loci functionality”)
- The reusability of already created constructions (“modular construction”)

An example (<https://www.geogebra.org/>) for the use of tracing to create a locus is shown in Fig. 8. There two points A and B and a segment CD were selected randomly. Then two circles

with the same radius – the length of the segment CD – were drawn around the two points A and B. One of the intersection points (E) was traced, while the length of the segment CD was varied. The red line of all the possible places of E is the locus – the perpendicular bisector of A and B.

Of course, the interactive or dynamic feature is the main issue, which cannot be demonstrated in a printed book.

Some well-known DGS are Geometer’s Sketchpad (<http://www.dynamicgeometry.com/>),

Technologies in Mathematics Education,
Fig. 6 Example virtual manipulatives impossible building blocks (Source: <http://www.fisme.science.uu.nl/toepassing/28432/>)

GeoGebra (<https://www.geogebra.org/>), Cabri-Géomètre (<http://www.cabri.net/cabri2/accueil-e.php>), Cinderella (<https://cinderella.de/tiki-index.php>), and many others.

The classical DGS were only meant to work in the Euclidean 2D geometry with some exceptions like the projective or hyperbolic geometry (Cinderella). About 10 years ago, DGS expanded into the third dimension. Nowadays 3D versions (Cabri-Géomètre 3D (<https://cabri.com/en/cabri-3d/>)) or additions (Geometer's Sketchpad,

GeoGebra) are available. Figure 9 shows an example of spatial geometry – a perpendicular triangular pyramid. Here the main advantage is the possibility to rotate the construction and to select different viewpoints.

Computer Algebra Systems

Computer Algebra Systems (CAS) like Maple (<https://www.maplesoft.com/>), Mathematica (<https://www.wolfram.com/mathematica/>), MATLAB (<https://www.mathworks.com/>), or the open-source version Maxima (<http://maxima.sourceforge.net/>) are tools for the manipulation of symbolic and numerical expressions and are used mainly at university level and in scientific or engineering contexts. CAS can solve equations symbolically and give i.e. the derivation or the integral of functions. For school mathematics, these tools are much too powerful, but there are versions adapted to the needs of mathematics classrooms. GeoGebra (<https://www.geogebra.org/>) has also extended features of a CAS suitable to high school mathematics. The main application of CAS in schools is the use of this software in graphic calculators especially in programmable graphing calculators.

Figure 4 gives an example on how to use CAS in calculus. The introduction of this software at the end of the 1980s led to a very heated discussion about the need for change of the typical mathematics classrooms where students were focused on acquiring the skills to manipulate algebraic expressions often without deeper understanding (Herget et al. 2000). The shift of the focus in calculus in the last 20 years toward mathematical modeling was a consequence of the introduction of CAS in mathematics teaching.

Programming Languages

In the 1970s, Seymour Papert (1980) and others introduced programming into mathematics education in primary schools. Most of the groups from all over the world taking up these ideas followed a constructivist teaching approach. Their aim was to

	A	B	C
1	Complete the missing entries in the table!		
2			
3	Example: 2% = 2/100 = 1/50 = 0,02		
4			
5	Percentage Rate	4%	
6	Hundredth fraction	5/100	☹
7	Reduced fraction	1/25	☺
8	Decimal number	0,4	☹
9			
10	Percentage Rate	2%	☺
11	Hundredth fraction	2/100	☺
12	Reduced fraction	1/50	
13	Decimal number	0,5	☹
14			
15	Percentage Rate		☺
16	Hundredth fraction		☹
17	Reduced fraction		☹

Technologies in Mathematics Education, Fig. 7
Example spreadsheet with automatic feedback

use programming, at that time with the languages Logo or BASIC, as a “thinking tool.”

Figure 10 shows an example of a Logo program to draw recursively a binary tree with the length 150. Programming or rather the program’s reaction is used to let students check their mathematical concepts or mental models and to develop them further.

Recently new projects take up these ideas of programming in primary mathematics classrooms using the language Scratch (i.e., Benton et al. 2017).

**Learning Environments/Intelligent
Tutorial Systems/Apps/Specific
Applications**

For a long time, learning environments for all age groups and mathematical topics have been created both commercially and open sources. Usually the technical features are the same as in learning environments generally, except the math-specific parts, which consist more or less of the abovementioned technologies. In addition, probably due to an affinity of mathematics teachers to

Technologies in

 Logo (Source: <http://fmslogo.sourceforge.net/>)

programming, there are countless little applications available in the World Wide Web for some specific mathematical aspect. These are often very helpful to give students the opportunity to explore mathematical questions or to practice their skills. A great collection can be found at <https://illuminations.nctm.org> or <http://www.bbc.co.uk/education> and on many other sites.

Further all the mathematical topics covered in schools and even most of university level are available in the World Wide Web as scripts, Wikipedia entries, or YouTube videos.

Conclusion

Technology and mathematics education are deeply intertwined and have a long history as well as a promising future together. The main message is that always the pedagogical questions regarding mathematics teaching and learning have to be considered first and the technology in mathematics classrooms is just there to support mathematics learning and understanding.

Introduction

Technology-enhanced learning (TEL) is concerned with using technologies to support learning whether the learning is local (i.e., on campus) or remote (at home or in the workplace). Historically, these technologies have included instructional films, radio, and television (Westera

2010), but in the current day, technology-enhanced learning pertains more to the use of computer-based technologies, including smartphones and other smart devices.

Learning can be considered as a process whereby the learner accesses concepts and ideas, assimilating these through practice and ultimately demonstrating mastery. Enhancements of learning seek to improve parts of this practice and process. With the progress of technologies, such enhancements are achieved through the facilitations of fundamental activities of learning by technology in various forms. Thus, what technology-enhanced learning ultimately offers are scalability, flexibility, and new methods of facilitating learning.

Recent applications and developments in TEL have displayed a wide variety of approaches including computer-based learning, courseware, m-learning, virtual learning environments, immersive learning environments, computer-based assessment/e-assessment, open learning, and collaborative technologies. This entry will consider the history and development, as well as the effectiveness of various approaches, of technology-enhanced learning.

Definition

Technology-enhanced learning (TEL) does not have a precise definition but instead encompasses a wide range of information and communication technologies that have been applied to teaching and learning (Kirkwood and Price 2013). “E-learning” was previously used to describe these technologies; however, definitions for “e-learning” also differed with definitions being generally classed into technology driven, delivery system oriented, communication oriented, and educational paradigms (Guri-Rosenblit and Gros 2011).

In view of the fluidity of definitions, it would be useful to define “technology-enhanced learning” as being any computer-based technology that supports learning.

Advantages of TEL

There are several advantages of technology-enhanced learning. In the research literature, studies usually describe these advantages in terms of operational improvement, quantitative change in learning, and qualitative change in learning (Kirkwood and Price 2013).

Operational improvement refers to enhancements that improve the learner's experience with the learning resources. Many studies (Copley 2007; Taylor and Clark 2010) that describe this enhancement note that technology-enhanced learning provides better accessibility to the learner compared to the conventional resources.

Meanwhile, quantitative changes in learning look at improvements in the learner's knowledge after technology-enhanced learning intervention has been carried out. Typically, this is done through pre- and posttest questionnaires, and the enhancement is quantified by looking at the difference in score between these two tests (Salkind 2010).

Qualitative changes in learning are concerned with skills developed by the learner because of technology-enhanced learning. These skills include higher-order thinking skills, reflection, and increased interaction between students (Kirkwood and Price 2013).

Pedagogical Concepts of TEL

Technology-enhanced learning is a useful tool for teaching and learning. In the wake of increasing use of technology-enhanced learning, "new" pedagogical concepts have been identified and developed. These concepts have informed educators in their development of effective practices in the use of technology-enhanced learning.

Several practices have been identified as effective practices in online learning which include (Bailey and Card 2009):

1. Encourage contacts between students and faculty in and out of classes.
2. Learning is enhanced when it is more like a team effort than a solo race.

3. Active learning is encouraged in classes that use structured exercises, challenging discussions, team projects, and peer critiques.
4. Students need appropriate and timely feedback on their performance to benefit from courses.
5. Learning to use one's time well is critical for students and professionals alike.
6. Communicate higher expectations.
7. Provide a diverse delivery system.

Computer-Based Learning/Computer-Aided Instruction

Computer-based learning emphasizes the use of a computer as the platform for delivery. In the research literature, a variety of terms are used to describe this pedagogy such as "computer-based," "computer-assisted," and "computer-aided." However, they generally involve the same concept of being based around the use of a computer.

Computer-based learning is probably the widest category of technology-enhanced learning since most technologies currently use the computer as a means for processing and delivering the information to the learner. As such, most other technologies are essentially subsets of computer-based learning. In terms of their use in the classroom, computer-based learning has been on the rise in recent years. Meanwhile, in institutions of higher learning, students are assumed to be computer literate, and much of the learning material is disseminated through the computer by platforms such as courseware, which will be discussed in the next section.

There have been many studies considering the effectiveness of computer-based learning compared to conventional methods. Most studies concluded that computer-based learning is at least as effective or more effective than older, more conventional, methods. Passey (2013) in his qualitative meta-analysis review of studies found that learners using computer-based learning or computer-aided instruction (CAI) perform better than those receiving traditional instructions. This may be one reason for the increased adoption of computer-based learning,

especially by institutions of higher learning in recent years.

Multimodal Learning

Multimodality is a concept that considers the many distinct modes (various digital media formats) deployed to communicate with each other and to express various forms of external knowledge or content. Growth in digital formats of media, and accompanying accessibility to multimedia, has lent itself to effective use of multimodal applications in classrooms.

Contributions of multimodal content, especially affecting various forms of sensory stimuli affording student engagement, could be important for design of learning environments with multimodal resources. Many different learning approaches in terms of distinctive stimuli could be applicable for students in the present context of technology-enhanced learning (Passey 2013): *visual*, static images or videos used as educational resources; *auditory*, podcasts or audio input of videos; *kinesthetic*, handling interactive content on touch-enabled displays and in augmented and virtual reality object manipulation, involving motor skills; *social*, social interaction and discussion with peers or lecturers or others through face to face (F2F) or through social learning platforms like Facebook/Chat; and *interpersonal*, learner-learner or learner-facilitator interaction through either chats and discussion in virtual learning environments (VLEs) or shared documents (e.g., Google docs) or online voting/polling applications (Clickers) as discussed in the next section.

Multimodality characterizes intercommunication strategies in expression of the textual, aural, oral, spatial, and visual resources or modes (Murray 2013). The generative theory of multimedia learning (Mayer 1997) proposes that active learning involves the cognitive processes of integrating the various sensory stimuli (as outlined above), e.g., integration of related words (verbal) and images (visual) into coherent verbal and visual models for the mind. As an example, learners, as in medical students, tend to integrate information from various different related sensory

modalities as above, e.g., heart sounds with an image of a beating heart or verbal (explanation of a presentation) with nonverbal information (watching Microsoft (MS) PowerPoint slides of the same presentation) to asking questions and giving feedback to students into one meaningful experience.

Whether a student is a single preference learner or a multimodal learner (having at least two or more modes involved in learning) in the learning environment, the presence of various sensory media approaches can allow the flexibility in learning for varied student cohorts (Sankey et al. 2010). The variety of different digital technologies and media forms provides opportunities for teachers and mediators to integrate them into practice and design a balanced curriculum (Passey 2013). Topic-specific resources and software such as simulations and visualizations can support literacy, numeracy, motor skills, and widening understanding in the short-term and in the long-term (Shieh 2012).

On the aspect of effect of different media formats, Passey (2013) found from previous studies that learning gains were maximum for audio followed by text, text with graphics, video, and physical resources in decreasing order. In order to incorporate such multimodality in learning, equitable access to multiple resources, furniture as well as the computer hardware for accessing the digital resources, needs to be present within easy reach of all students. Hence, learning spaces need to be appropriately designed, affording multimodal representation of learning resources. One such design is the technology-enhanced learning environment (TELE).

Technology-Enhanced Learning Environment (TELE)

TELE has been defined by the Joint Information Systems Committee (JISC) as a specialist area that encompasses “virtual and physical technology-enhanced learning environments (incorporating physical learning spaces, institutional virtual learning environments, personalized learning environments and mobile and

immersive learning environments” (JISC 2011, para 1). Technologically-enhanced classrooms, a term more commonly used in academic settings, have varied in terms of information technology (IT) arrangements, which may differ among different classrooms (Vartabedian 2002).

TELEs are widely endorsed to “create new opportunities in teaching and learning by integrating networking, computers, and audiovisual technology” (Vartabedian 2002, pp. 4–5). Many such technology-enhanced classrooms commonly incorporate a combination of the following: liquid crystal display (LCD)/light emitting diode (LED)/light application by stimulated emission of radiation (LASER) projector and projection system; networked desktop computers or bring your own device (BYOD) wireless connections; stereo sound and microphone system; touch screen control; document camera; etc. These technologies are incorporated within a classroom that allows in more recent cases in many countries of group seating of students in a large flat floor space (Sen and Passey 2013).

TELE is becoming a useful arena for knowledge creation activities as it provides an “information-rich environment in which the student has control in discovering knowledge, but the discovery is supported and scaffolded by extra guidance functions, which provide support and feedback for subsequent learning” (Laurillard 2002). It can create a social space, supporting flexible interaction and simultaneously affording a comprehensive suite of multimodal resources. Such applications of TELE have now been the focus for incorporating active learning strategies within technology-enhanced classrooms.

Online Polling Applications/Clickers

Clickers or classroom/audience response systems (CRS) are handheld electronic devices or, as increasingly used nowadays, online cloud-based applications accessed through mobile telephones and used to elicit anonymous student responses to questions using electronic on-screen presentations. The results of students’ responses are also immediately displayed allowing instructors to

gauge the level of understanding of their students and allow students to reflect on their knowledge of the concept at hand (Sullivan 2009). Such technologies are a part of TEL that allows a valid and effective tool to identify various levels of students’ learning through evaluation (Sen 2012) and has been found to have good predictive value, usability, and benefits in a curriculum focused on interaction. There are a large number of such online polling tools that use either simple formats of quizzes or various forms of questions (Poll Everywhere) or even encouraging team-based competitions (Kahoot!).

Courseware

A subset of computer-based learning, courseware is a platform which delivers learning materials to the learner. Courseware was previously distributed by compact disk-read only memories (CD-ROMs), but newer initiatives such as the Massachusetts Institute of Technology (MIT) OpenCourseWare have also been developed as an application of courseware.

Courseware essentially offers a platform for educators to supply learning materials to the learner, be it via tutorials, lectures, or reading materials. Through these functions, courseware has the benefit of enhancing the accessibility of learning resources to the learner since the learning resources can be easily accessed by the learner using personal computers and devices.

In schools, courseware can be bundled with a textbook as an add-on that the teacher and student can choose to utilize. These have in the past typically taken the form of a CD-ROM attached to a textbook which the student can insert into a computer with a CD drive in order to run the application. In recent years, courseware in textbooks has taken the form of a code, which the student can enter into the publisher’s website in order to access additional features of the textbook. Through this, educational materials can be made available to the learner on demand, and the learner is free to learn at his or her own pace.

Newer applications of courseware include the aforementioned MIT OpenCourseWare, which is

a website where many of the tutorials, lectures, and reading materials from university courses are uploaded online allowing anyone to be able to learn from these courses.

M-Learning

M-learning or “mobile learning” is where the delivery platform is a mobile device (e.g., laptop, smartphone, tablet). With the advent of increasing versatility of mobile devices, many of the functions that previously could only be performed by a dedicated personal computer are now able to be performed by these mobile devices.

Many educational applications (apps) have been developed for mobile devices for schools. Some notable examples include Duolingo for language learning or the popular Khan Academy for various self-learning modules. Quizlet is a flashcard mobile app for practice of a variety of topics. More and more of these m-learning apps are gaining acceptance globally such that many of them now include foreign language support, images, and audio as well as encouraging social learning with the ability to share learning (flashcards in Quizlet) with friends. These serve to complement the classroom learning experience though social and out of class “anytime anywhere” learning.

Virtual Learning Environments

Other applications of specialized m-learning include applications in virtual reality and augmented reality, since mobile devices serve as easily available platforms that incorporates technologies including a camera with capabilities to connect to the web as well as use the audio and video within one device.

Virtual learning environments (VLEs) refer to “the components in which learners and tutors participate in ‘on-line’ interactions of various kinds, including on-line learning” (Weller 2007). Virtual learning environments can incorporate portals that provide access to learning support facilities, including course information,

communication (forums, messaging, announcements), course content (lecture notes and sources), and assessment and feedback.

Virtual learning environments allow for direct communication between the educator and the learners on an individual and group basis through messaging. Virtual learning environments also typically have the added capability to facilitate discussion between the educator and learners via online forums.

In recognition of the advantages of virtual learning environments, there is increasing adoption of virtual learning environments by many institutions of learning. Common proprietary systems used by these institutions which employ VLEs include Moodle[®], Blackboard, etc.

There have been recent advances in VLEs that allow users to create, share, and reuse interactive content in the form of an open-source content collaboration framework such as Hypertext Markup Language (HTML)5 Package (H5P) (Ti-Shen and Sen 2019). This has allowed the modern VLEs to incorporate interactive videos allowing active viewing of multimedia content while answering quizzes, giving feedback on the previous content watched, etc.

Immersive Learning Environments

Immersive learning environments are a newer technology that enables the participant to explore and learn in a simulated environment or virtual world. Some examples of immersive learning environments include augmented reality and virtual reality environments. Augmented reality refers to the “augmentation” of the actual environment with 3D objects and labels, whereas virtual reality refers to the creation of a virtual environment.

Augmented reality and virtual reality environments have been used in learning and have been found to be effective in improving learning outcomes (Ferrer-Torregrosa et al. 2016; Jamali et al. 2015; Küçük et al. 2016). Augmented realities using mobile telephones to display 3D models have been used as tools for visualization in learning. Meanwhile, many mobile

applications like Augment[®] or EON[®] which can augment onto real-life environments have already been used in simulation settings.

Virtual reality environments using virtual reality headsets have also been used as tools for visualization. A detailed description of how such augmented reality and virtual reality applications can be found in a related Springer Encyclopedia (Sen and Liew 2019).

Computer-Based Assessments

Computer-based assessments refer to utilizing computer technology to assess student work. These can incorporate multiple-choice testing, parsing of language, or comparison of symbolic (mathematical) expressions. They may be diagnostic, formative, or summative. Computer-based assessments can also be integrated into virtual learning environments (e.g., Moodle quizzes) as part of the ongoing learning process for learners, allowing learners and educators alike to assess the learner's understanding.

Computer-based assessments are also increasingly being used as the medium for examinations. Many examinations have already become computer-based (e.g., Graduate Record Examination (GRE), Scholastic Aptitude Test (SAT), etc.), and some professional examinations (e.g., Associate Chartered Accountant (ACA)) have moved toward a computer-based examination.

Open-Learning Platforms

Open-learning platforms are currently in vogue in technology-enhanced learning as a means of facilitating learning. Open-learning platforms allow for sharing of learning resources through open licensing and agreements, e.g., massive open online courses (MOOCs). Some of these massive open online course initiatives include sites such as edX[®], Coursera[®], and Great Courses Plus[®].

Open-learning platforms have the benefit of being available to the general public, rather than being restricted only to the members of a particular institution. Open-learning platforms also

provide an outlet for educators in institutions to reach out to a wider audience of learners by providing tutorials and lectures to the public which, otherwise, would not have been easily available to the public.

Web 2.0 (Collaborative Technologies)

Web 2.0 refers to “the web as a platform” (Graham 2005). Web 2.0 was a development from Web 1.0, emphasizing the paradigm shift in the World Wide Web from applications to platforms (O'Reilly 2005). As a development in information technology, Web 2.0 offers community and user involvement that maps well onto many learning activities. Many technology-enhanced learning approaches that utilize the World Wide Web already use Web 2.0 as the basis for their functions.

Future Directions and Developments

The future of technology-enhanced learning moves in cadence with advances in information and related technologies. Many technologies have increased in popularity since the early days of technology-enhanced learning. The latest in the trend of technology-enhanced learning is social media technology, which has led to questions regarding their use in education (Scott 2015).

Meanwhile, the pedagogical practices behind the use of augmented and virtual reality environments as well as other educational technologies incorporated as TEL is currently an area of interest in research and there remains much to be investigated regarding their uses in education.

Incorporating most of the technologies that enhance active learning (VLE, m-learning, TELE, immersive technologies, etc.) as described in the previous sections as examples of some of the effective practices through research results, Sen and Selvaratnam (2012) designed a futuristic Technology-Enhanced Learning Laboratory – the Medical Anatomy and Pathology E-Learning (MAPEL) Laboratory – as a physical learning environment that integrates spaces, technology, and resources, with active learning pedagogies for large

student cohorts. Complex resources like digital textbooks, physical specimens and models, videos and digital image repositories, and augmented reality and virtual reality federations of specimens and body spaces were incorporated as resources within a collaborative oval table setup for multiple student groups, thus encouraging student-student, student-resources, and student-teacher interactions. These interactions were encouraged through various technology uses including a network of multi-touch tabletop computers, high-resolution projectors and multiple screens for a 360° view, document cameras, video cameras, and multicasting from BYOD teachers' tablets to screens, while the teacher is moving around groups of students. Use of the award-winning MAPEL Laboratory was found to engage students in diverse learner-resources-technology interactions and higher-order learning.

Conclusion

Technology-enhanced learning is a valuable tool in the classroom of the twenty-first century. With the development of many new technology-enhanced learning approaches, many new pedagogical concepts and practices have been developed and refined to better appropriate the advantages that technology-enhanced learning brings. With these advantages, technology-enhanced learning is poised to spearhead the learning revolution of the century.

Introduction

Technology-enhanced learning (TEL) is increasingly influencing university education, mainly in overcoming disadvantages of direct instruction teaching approaches, and encouraging creativity, problem-solving, and critical thinking in student-centered, interactive learning environments. Programming is a field of studies that is accompanied with many difficulties, and TEL tools and services can improve significantly the teaching and learning of programming.

In this entry, the focus is on utilizing TEL in programming courses and more specifically on object-oriented programming (OOP) courses in higher education. The following aspects of TEL tools and services:

- Programming environments and tools
- Automated assessment tools
- Learning management systems (LMS) and tutoring systems

are examined taking into account the relevant literature and the experiences from OOP courses taught in three institutions from three different European countries. These institutions are the University of Macedonia, Thessaloniki, Greece, Department of Applied Informatics (UOM-DAI) and Department of Technology Management (UOM-TMD, since 2013 merged with UOM-DAI); University of Novi Sad, Novi Sad, Serbia, Faculty of Sciences (UNS-PMF); and University of Masaryk, Brno, Czech Republic, Faculty of Informatics (MUNI-FI). More information about the courses and a comparison between them can be found in (Ivanović et al. 2015, 2017). The three institutions have invested greatly in the advantages of TEL and their usage in delivering OOP courses. Several programming environments and systems have been developed in the three institutions for supporting the OOP courses, including the programming microworld objectKarel (Xinogalos et al. 2006), the distributed pair programming system SCEPPSYs (Tsompanoudi et al. 2016), the Svetovid system for supporting program development and assessment (Pribela et al. 2009; Pribela and Pracner 2017), a Moodle extension with personalization features, and in-house LMS. Besides these TEL environments and tools, well-known environments, such as BlueJ (Kölling et al. 2003) and Jeliot, are heavily utilized.

The rest of the entry is organized as follows. In the next section, an overview of the various types of programming environments and tools is presented, followed by research results and experiences on utilizing various programming environments and tools in teaching OOP courses. The third section presents information on automated assessment tools of programming assignments, as well as experiences from devising and utilizing such systems. The fourth section focuses on LMS and tutoring systems, types of relevant systems, typical uses of such systems in the OOP courses at the three institutions, and the results of

a survey regarding students' perceptions on the importance and utilization of TEL services (usually incorporated in LMS) especially for programming courses. Finally, some conclusions on the role of TEL in programming courses are drawn.

Programming Environments and Tools

Overview

Students learning programming face great difficulties with syntax and semantics of programming languages. These difficulties are exacerbated by the lack of support from programming environments when it comes to developing programs and understanding error messages and flow of control. In order to support students in dealing with these difficulties, different educational *programming environments and tools* have been developed and used in CS1 but also intensively in subsequent programming courses. Typically, environments of this kind aim to make the process of programming easier for students as well as to motivate them. For example (Xinogalos and Satratzemi 2004):

- *Structure editors* are used for developing programs through templates and menus and avoiding syntax errors.
- *Compilers that report user-friendly errors* are incorporated for supporting students in debugging their programs.
- *Step-by-step execution* of programs, or else *program animation*, is provided for understanding the semantics of programming constructs and flow of control.
- *Visualization* of the results of a program during execution is used for comprehending abstract programming concepts and constructs.

The main types of programming environments and tools utilized in programming courses are the following:

Programming microworlds (Brusilovsky et al. 1998) aim at using a simple language with a limited instruction set, as well as a metaphor familiar and attractive to students that is depicted on the screen. A well-known microworld

metaphor is that of a world of robots in Karel++ (Bergin et al. 1997). Programming microworlds commonly use step-by-step execution and visualization of program execution results (Xinogalos et al. 2006). A well-known OOP microworld based on Karel++ is Jeroo (Sanders and Dorn 2003). Another microworld based on Karel++ is objectKarel (Xinogalos et al. 2006) that was designed and developed at UOM-DAI. objectKarel uses a *structure editor* for guiding students through program development and avoiding syntax errors; *step-by-step execution* (program animation) with the current statement being highlighted and the robots “showing” the result in the world; *explanatory visualization* for presenting explanatory messages in natural language during the step-by-step execution of the program for supporting students that find it difficult to follow the flow of control; user-friendly and *highly informative error messages*; and a *learning module* including brief and concise theory and hands-on activities with the aim of supporting students in comprehending OOP concepts before implementing them. objectKarel has been used for several years at UOM-TMD for a brief two-lecture introduction to OOP concepts.

Educational programming environments use either an educational or a conventional programming language and aim at supporting students in dealing with difficulties through aids such as software visualization techniques, simplified user interfaces, and enhanced error reporting. The most well-known educational programming environment for OOP and Java is BlueJ (Kölling et al. 2003), which has all the aforementioned features and the possibility of direct manipulation of classes and objects. Specifically, students can experiment with existing projects: create objects by interacting with a simplified class diagram, call methods by interacting with the existing objects that are depicted in an object bench, and inspect an object’s situation during execution. The BlueJ environment has been used with positive results in all three institutions (Ivanović et al. 2015).

Algorithm and program visualization tools visualize the structure of a program or the results of its execution. Such tools can visualize either the

static or the dynamic aspects of a program (Pears et al. 2007). Jeliot (Ben-Ari et al. 2011), for example, is a code visualization tool used for supporting students in comprehending the dynamic aspects of OOP. It can be used as a plug-in for BlueJ as well. Students at UNS-PMF are encouraged to use Jeliot for code visualization.

Distributed pair programming (DPP) systems aim to achieve the advantages of pair programming (PP), but they moreover give students the chance to collaborate from anywhere and at any time. Each time one of the students has the role of the driver and writes code, and the other has the role of the navigator and monitors and comments on the code of his/her partner. Widely known advantages of PP are the exchange of knowledge, design quality, code productivity, team building and communication, and satisfaction. Several plug-ins for the widely used Java Integrated Development Environment (IDE) of Eclipse have been developed, such as Sangam, RIPPLE, XPairtise, Saros, and SCEPPSys. SCEPPSys (“Scripted Collaboration in an Educational Pair Programming System”) was designed and implemented at UOM-DAI, and it was utilized for several years for carrying out homework assignments for the compulsory OOP course (Tsompanoudi et al. 2016). SCEPPSys utilizes collaboration scripts that define the turn-taking policy, a sequence of programming tasks, and corresponding hints for guiding students.

More recently, *educational games for programming* (Malliarakis et al. 2016) have been developed for supporting students in dealing with difficulties and improving their performance. Educational games succeed in this mainly by motivating students through their immersive qualities. Several educational games for programming, such as CMX developed at UOM-DAI, have been developed, but most of them refer to younger students or imperative programming.

A well-known environment that is used for teaching OOP with Java is Greenfoot (Kölling 2010) that combines features of a programming microworld and the educational programming environment BlueJ and enhances the teaching and learning of OOP through the development of simple games.

Experiences on Utilizing Programming Environments

The Educational Technology Research Group at UOM (EdTechRG|UoM) has invested a lot of work in designing, implementing, and utilizing programming environments that promote TEL of programming. The programming microworld objectKarel and the DPP system SCEPPSYs that were designed and implemented by EdTechRG|UoM as well as the educational programming environment BlueJ were heavily utilized in OOP courses at UOM-TMD and UOM-DAI, and several studies were carried out regarding their effectiveness.

objectKarel was initially evaluated by students at UOM-DAI. Based on the results of this study (Xinogalos et al. 2006), the microworld approach to teaching programming was positively evaluated; the structure editor helped the vast majority of students in implementing their programs; step-by-step execution supported all the students in debugging and comprehending OOP concepts; and friendly error messages helped the vast majority of students in understanding and correcting the errors. Besides this pilot usage, objectKarel was used in the context of an undergraduate OO design and programming course for six consecutive years in order to introduce students to OOP concepts prior to Java at UOM-TMD. More specifically, objectKarel was used in the first two lectures of the course for helping students comprehend fundamental OOP concepts, such as objects, classes, and inheritance, prior to using Java for implementing these concepts. What is important is that the knowledge acquired in the context of the microworld was transferred afterward to Java (Xinogalos 2012). This brief introduction to OOP with objectKarel was followed by the use of the educational programming environment BlueJ. The combined use of the two environments had a positive impact on students' understanding of objects and classes and their achievements in the course (Xinogalos 2015). BlueJ, as already mentioned, was also utilized in UNS-PMF and MUNI-FI (Ivanović et al. 2015). NetBeans has recently been added as an IDE for students at MUNI-FI, while teachers still use BlueJ at lectures due to its simplicity and clarity

when using a beamer for projection. UOM-DAI utilizes mainly the Eclipse IDE.

The DPP system SCEPPSYs was utilized at UOM-DAI for carrying out homework assignments at the context of the compulsory OOP course. Based on a survey, students evaluated positively the overall experience on DPP assignments and expressed their preference in carrying out assignments collaboratively (Xinogalos et al. 2017). According to students, the benefits of DPP assignments are not just sharing of knowledge and skills, being more confident for their solution, and better code quality. Learning programming is more pleasant when DPP assignments are used, students feel more responsible being a member of a pair, and correcting syntax and logic errors becomes easier. Another study carried out in the course showed that the use of DPP improves pass rates, while the use of collaboration scripts yields equal task contributions from each member of the pair (Tsompanoudi et al. 2016).

MUNI-FI and UNS-PMF do not use any DPP system, but contemporary source code management systems, namely, Git with a local instance of Gitlab, are extensively employed to support labs in Java courses. MUNI-FI students pull source codes of their tasks from the repository and in some lab groups; they also submit their solutions this way allowing automated assessment by the lab tutors, as analyzed in section “[Automated Assessment Tools](#).” Similarly, at UNS-PMF, students submit their solutions for particular tasks this way allowing automated assessment by the lab tutors.

Automated Assessment Tools

Overview

Besides programming environments and tools, another important aspect of any programming course are programming exercises solved at labs and also assigned to students as homework. The assignment of exercises and submission of solutions, communication and collaboration during problem-solving, access to educational material, and assessment of assignments are usually accomplished with the help of LMS (Govender and

Govender 2010) and automated assessment tools (Pears et al. 2007).

Automated assessment tools automate the assessment of assignments and provide students and/or instructors with immediate feedback. Such tools can fully automate the grading of assignments, especially in cases of large numbers of students, or carry out an initial evaluation and indicate problems in students' programs (Pears et al. 2007). Moreover, automated assessment tools can check the coding style and specific design aspects of a program, as well as the usage of specific language features (Pears et al. 2007). In some cases, assessment tools provide the capability of *online submission* as well, as is the case with BOSS and Web-CAT (Rößling et al. 2008).

Experiences on Utilizing Automated Assessment Tools

Homework assignments at UOM-TMD in the past and UOM-DAI currently are corrected manually by the instructors. However, in the case of DPP assignments, SCEPPSYs records information during problem-solving and reports various statistics that provide a form of an initial evaluation and can indicate problems in students' programs. Statistics are reported for each pair of students and for the whole class (mean value) as well: total time spent to solve a project (min), driving time spent to solve a project (min), number of project runs, number of role switches, number of retrieved hints, contribution of each student (number of characters), contribution of each student (in %), number of steps solved according to role distribution policy, and messages sent by each student through the incorporated chat tool. Although the instructors have to manually assess the assignments, the aforementioned statistics can assist in (Xinogalos et al. 2016) detecting difficulties with specific OOP concepts/constructs, detecting students' progress in programming, detecting undesirable behaviors (e.g., plagiarism), and detecting problems in collaboration between the members of a pair.

UNS-PMF has been using for more than 10 years the in-house assessment tool Svetovid, which is an interactive development environment integrated with a secure submission system for students' lab and/or homework solutions. The

initial version of the system represented the first layer of defense preventing students' cheating. In the meanwhile, the system has been evolving, and the use of ubiquitous social media platforms influenced the implementation of a second layer of defense. This second layer represents detection and investigation of any wrongdoing and is enabled by tracking of history and evolution of the student's solution through time. To address this and the other problems, Svetovid implemented a special file system where Git was adopted (Pribela and Pracner 2017). Such innovation has some advantages. This means that not only the final submitted version is stored and the student could restore an older version of the assignment that was possibly more correct. The teacher can also have a better understanding of the development process of the solution and can evaluate its evolution and not only the final state.

MUNI-FI uses a semiautomated system for assessment of students' homework. They either submit their solutions using the in-house developed information system of MUNI or push their solutions to Gitlab. In both cases, their submissions are subject to semiautomated process when the tutors run the unit tests provided (and known to students prior to submission). In addition, students are forced to follow the Java coding conventions by Checkstyle. A different regime applies to in-class tests where the students have limited time to deliver a working program as their solution; the program must compile and produce the desired result which is, however, tested manually.

Learning Management Systems

Overview

The utilization of an LMS in a programming course is considered important. Past research found that students' satisfaction with TEL services tends to be positively correlated with different factors such as:

- Course content and quality (Naveh et al. 2010; Selim 2007; Sun et al. 2008).
- Instructors' attitudes toward technology-enhanced learning and students' technical competency (Selim 2007; Sun et al. 2008).

- Diversity in assessments (Sun et al. 2008).
- The existence of bulletin boards and discussion forums (Basioudis et al. 2012).
- Efficient transmission of course materials and announcements (Lonn and Teasley 2009).
- Actual use and students' involvement (Klobas and McGill 2010).

The study by Emelyanova and Voronina (2014) indicated that there is a remarkable divergence of students' and teachers' perceptions of LMS regarding their usefulness, appropriateness, and interest for the students. In a recent literature review of students' usage of LMS, Lust et al. (2012) showed that students generally perceive LMS as useful and easy to use.

LMS in general are heavily used for enhancing the learning experience of students by providing them access to educational material, improving communication and collaboration, and aiding in testing of the acquired knowledge. In the case of programming courses, students expect to receive even more enhanced support from the LMS, such as support in problem-solving (Govender and Govender 2010). As mentioned in the report of the ITiCSE 2008 "Working Group on Design Patterns for Online Learning Environments in Computer Science," the features of a typical LMS do not meet certain needs of Computer Science Education (Röbbling et al. 2008). For this purpose, an LMS that is extended specifically for CSE is proposed and referred to as *Computing Augmented Learning Management System* (CALMS) (Röbbling et al. 2008). Thota and Whitfield (2009), for example, report on the ongoing development of a CALMS based on Moodle for an introductory programming course, which they envision to enrich with facilities for automatic assessment and plagiarism detection, automatic feedback for programming assignments, and peer evaluation of programming assignments.

Experiences on Using LMS and Tutoring Systems

At UNS-PMF, students can use Moodle with extended personalization features (Komlenov et al. 2010; Verpoorten et al. 2009) or the in-house developed intelligent tutoring system Protus. Protus is a multifunctional e-learning environment

for supporting intelligent tutoring and some elements of personal and pedagogical assistance agents (Ivanović et al. 2018). The OOP course within Moodle consists of teaching materials and a mix of synchronous/asynchronous activities and resources. The e-lessons are used as asynchronous activities, such as quizzes, glossaries, wikis, and discussion forums. In addition, live discussions occur regularly; some of the resources used during lab exercises and assignments are formulated and graded online and then solved individually during regular classes. On the other hand, Protus has been designed to support students with personalized courses that include teaching material but also elements for testing of acquired knowledge. Protus has been increasing the learning opportunities, challenges, and efficiency supporting adaptive learning based on learning styles and recommender systems. Protus also supports scaffolding teaching that helps students to understand better and adopt difficult OO programming concepts.

Such assistance can help the students in different ways: suggest them to take the most suitable learning actions, monitor students' progress, track students' cognitive learning styles, and offer highly learner-adaptive environment.

At UOM-TMD, UOM-DAI, and MUNI-FI, an in-house LMS is used, which is however used for all courses at the corresponding institutions. The LMS used in the three institutions have all an integrated discussion forum and an email system that are heavily used for communication and collaboration. Typical usage scenarios of LMS services are presented in Table 1.

Students' Perceptions on the Utilization of TEL Services Provided in LMS

To the best of the authors' knowledge, there are only two comprehensive studies providing an international comparative analysis of students' perception of learning management systems and accompanying TEL features and services (Basioudis et al. 2012; Ivanović et al. 2017). The study by Basioudis et al. (2012) investigated how undergraduate accounting students from the UK, Australia, and New Zealand perceive the importance of generic TEL features present in LMSs. The main conclusion of the analysis is that student satisfaction with the use of an LMS is strongly

Technology-Enhanced Learning in Programming Courses, Role of, Table 1 Typical usage of LMS in programming courses

	Course's description	Calendar	Documents	Students' assignments	Discussion forum	Announcements
<i>Course organization and management</i>	Provides important info that plays the role of a didactical contract between students and the instructor	History of lectures/labs	The structure of folders depicts the organization of lectures/labs. Folders and files can be easily (de) activated during the preparation of a unit	Assignment of weekly homework is realized exclusively through the system, saving class time. Students' solutions can be downloaded organized in folder		Announcements regarding important scheduled (i.e., lectures/labs, exams) and unscheduled events (i.e., changes in program) can be posted and sent by email to enrolled students
<i>Student guidance</i>	Information regarding the general didactical aims, course content, textbooks, software, learning design, and grading policy guide students through the course	Provides information for the content and the material of each lecture/lab carried out and where it can be found in the system	Students know that the last visible folder represents the most recent lecture	Students have available the necessary homework material and submission deadlines		Students are guided by the instructor through the semester for all important events
<i>Enhanced learning</i>	All the necessary course information is available online, which reduces students' anxiety and supports them in planning their learning	Provides information for catching up with missed lectures/labs	Availability of PP slides and the material used at lectures allows students to concentrate on understanding what is presented and not just keeping notes, while the material is error-free. Material is available from anywhere	Easy online submission of assignments at any time and as many times as wanted (within the deadline) from anywhere, as well as ability to submit part of the assignments, motivates students to do their homework, which is essential for learning programming	Through many to many communication	

(continued)

Technology-Enhanced Learning in Programming Courses, Role of, Table 1 (continued)

	Course's description	Calendar	Documents	Students' assignments	Discussion forum	Announcements
<i>Communication and collaboration</i>					Students can ask for help regarding queries on theory, assignments, and so on and get feedback from colleagues and the instructor	
<i>Support in problem-solving</i>			Supplementary material, such as commented programs, can be provided for supporting students in problem-solving	Guidelines and hints can be added at any time in the "assignments area" based on students' questions, helping students get unstuck and finish their assignments	Students are encouraged to use the forum for getting help from colleagues and the instructor during problem-solving (homework)	Announcements are made for supporting students in problem-solving in the case that the instructor finds out that homework has any unclear specifications or it is too challenging for students

influenced by the availability of lecture notes and the utilization of online assessment, announcements, model answers, and online chat features.

In one of the authors' previous studies (Ivanović et al. 2017), a survey was carried out in order to analyze students' perception and actual utilization of TEL services supporting the teaching of object-oriented programming courses at three institutions. The analysis included not only TEL services currently used within OOP courses but also TEL services planned to be used in the future. The most important information for this study is given in Table 2.

The analysis of collected questionnaire responses revealed that students perceive the usage of LMS and Moodle for the distribution of didactical material and the organization of assignments as very important or absolutely essential. Announcements and automatic notifications enabled by LMS/Moodle are also considered as very useful. Although considered as important TEL services, LMS/Moodle forums tend to be rarely used by students. As the main reasons for not posting on forums, students indicated that (1) they did not need

LMS forums to communicate with teachers and colleagues and (2) they did not want other enrolled students see their questions. A similar situation was observed regarding the usage of instant messaging (IM) tools to communicate with instructors: students prefer more to use e-mail or to approach instructors personally rather to use IM tools.

The second part of the questionnaire asked respondents to evaluate the importance of features that could be offered by TEL tools. Students evaluated supplementary education material and exemplary solved problems given on LMS as highly important, while online self-evaluation quizzes, the adaptability of e-lessons, and tracking learning style are considered as important TEL services.

Nonparametric statistical test revealed a high similarity between UNS-PMF and MUNI-FI students with respect to the perceived importance of TEL services. On the other hand, students from UOM-TMD gave significantly higher ratings to the use of CMS for assignments and the distribution of didactical material, the adaptability of e-lessons, and tracking learning style LMS features. The observed difference can be explained by the nature

Technology-Enhanced Learning in Programming Courses, Role of, Table 2 Information for the study investigating students' perception and actual utilization of TEL services used in teaching object-oriented programming

Participants	93 students from the University of Macedonia (UOM-TMD), Greece 80 students from Masaryk University, Czech Republic 113 students from the University of Novi Sad, Serbia 286 students in total
Questionnaire	13 questions separated in two parts <i>Questions of the first part:</i> importance and utilization of TEL services used for teaching object-oriented programming at the authors' three institutions (the organization and distribution of teaching material, assignment services, communication, and cooperation services) <i>Questions of the second part:</i> perceived usefulness of TEL services planned to be used in the near future (online self-evaluation quizzes, supplementary educational material and exemplary solved problems in electronic forms, and adaptability of e-lessons according to learning styles) <i>Five-point Likert scale was used:</i> not at all (1); slightly (2); averagely (3); much (4); very much (5).
Statistical analysis	The internal consistency of collected questionnaire responses was assessed using Cronbach's alpha coefficient Median and mode were used to determine central tendencies in students' responses to questionnaire items. The interquartile range was employed to measure variability in responses Nonparametric statistical tests (Kruskal-Wallis ANOVA, Mann-Whitney U, and two sample Kolmogorov-Smirnov tests) and probabilities of superiority were used to compare questionnaire responses of two or more independent groups of students determined by various criteria (institution, year of study, the average grade)

of the UOM-TMD computer science study program which is more oriented toward technology management compared to computer science study programs at UNS-PMF and MUNI-FI. The statistical analysis also revealed that the perception of the importance of TEL services does not tend to be significantly associated with study year and students' average grade.

Conclusions

TEL can play an important role in the teaching and learning of programming, no matter what the programming technique and language are. This entry focuses on OOP courses, but the results apply in any programming course since the TEL services analyzed are independent of the programming techniques, while similar TEL tools examined for OOP exist for other programming techniques as well.

An important aspect of an OOP course is the programming environments and tools utilized in labs and assignments for practicing programming. A wide list of environments is available for OOP that cover the different needs of students. For example, programming microworlds can be utilized for introducing non-computer science (CS) majors to OOP concepts smoothly. Educational programming environments utilizing Java, such

as BlueJ, can be used in any case. DPP programming systems based on the professional Java Integrated Development Environment Eclipse can be utilized by CS students for carrying out homework assignments, while code visualization tools can be used for comprehending the dynamic aspects of object-oriented programs.

Another important aspect of a programming course is providing immediate and accurate feedback on students for their programming assignments. In case of big numbers of students attending a course, this can be actually accomplished only by utilizing automated assessment tools. Tools that record information during problem-solving and calculate and report various statistics can also help instructors monitor the achievement of the didactical goals of their courses.

Finally, an important aspect of any programming course is orchestrating and managing lectures, labs, announcement and submission of homework assignments and projects, delivery of educational material, providing support during problem-solving, and communication with and between students. All these can be accomplished through a typical LMS or even better with an LMS enhanced with services specifically for delivering programming courses. Based on a survey carried out in the authors' institutions, but also in previous studies, it came out that students perceive the

usage of TEL tools for organization and distribution of teaching material, assignment activities, and announcements as either very important or absolutely essential. Forums provided by TEL tools are also considered very important, although they are not extensively utilized especially in cases where the students have the choice of face-to-face communication with instructors. The survey also indicated that students show very high interest in exemplary problem solutions and supplementary educational material in the form of e-lessons, as well as personalization features.

Concluding, existing TEL tools and services can enhance the teaching and learning of programming courses. Several possibilities for even more elaborated TEL tools and services for programming courses exist that require further work in the field.

Introduction

Parents of schoolchildren want to be well informed and know as much as possible about their children's school and how their children are progressing at school. In 2010 the State Government of Victoria, Australia, launched an online system, the Ultranet, for connecting and

informing school communities using web-based technology. The Ultranet was launched in 2010 and, after a short life, finally abandoned in June 2013. This entry addresses the socio-technical nature of the Ultranet, its development, and the possibilities it offered and examines why they did not fully eventuate.

The Ultranet was intended to support knowledge sharing across Victorian Government Schools and to be used by over 540,000 students and their parents in 1,555 government schools along with their 40,000 teachers (Australian Bureau of Statistics 2010; DEECD 2010b). It was intended to provide facilities for keeping parents informed about their children's schooling as well as for curriculum delivery and online teaching and learning. Traditionally, parents were kept informed about their child's progress at school through the use of printed school reports, parent-teacher evenings, and an annual "Open Day." Reporting in some form is important as parents all want to know as much as possible about the school where their children spend so much time and also how well they are progressing (Davey and Tatnall 2012). At this point the Ultranet entered the scene (Fig. 1).

Ultranet Background

Altgh many education systems around the world have made use of tools like those found in learning management systems such as Blackboard

Ultranet, Fig. 1 What is the Ultranet? (DEECD 2011b)

and Moodle for online teaching and learning, the Ultranet was quite different in that it was designed to also provide information to parents.

The Ultranet was designed for three principle uses (Tatnall and Dakich 2011):

- To allow student access to personalized learning activities and keep an ongoing record
- To allow teachers to create curriculum plans, collaborate with other teachers, monitor student progress, and manage student assessment
- To allow parents to view information to help them keep up to date with their child's learning.

The Ultranet had many of the features of a business extranet in that it was closed to people outside the Victorian Government School community and required a username and password to gain access (Davey and Tatnall 2013) (An **extranet** is a private network (based on web technologies) that links selected parts of

an organization's intranet with its customers, suppliers, and other authorized business partners.).

The Ultranet was based on the use of what it called Spaces, each of which was intended to allow different information to be accessed and different learning activities to be performed (Tatnall 2011). Each Space was classified by its accessibility into one of the following categories:

- **Me Spaces** were private spaces accessible only by the owner.
- **We Spaces** were shared spaces seen by those with permission to be in that space.
- **See Spaces** were public, open-access spaces that could be seen by the whole world.

These spaces were:

1. **Home** – a personalized page for students, parents, and teachers to see school or community

- notices and where students and teachers could add their favorite applications (a Me Space).
2. **eXpress Space** – a personal We Space for students and teachers to capture, share, and reflect on their learning.
 3. **Design** – a Me Space for teachers (only) to plan, create, and collaborate with colleagues within and across schools and design curriculum and student learning activities.
 4. **Community** – a space where students, parents, and teachers could find school news and events and be involved in school-based groups, clubs, or activities (a We Space).
 5. **Collaborative Learning** – where students could take part in online learning activities set up by their teachers (a We Space).
 6. **Learner Profile** – a We Space where students, their parents, and teachers could view a detailed profile of students' individual learning progress.
 7. **Learning Tasks** – a We Space for teachers to plan, deliver, and assess learning activities and for students to view and submit learning tasks.
 8. **My Content** – a space where teachers and students could store and search for personal, school, and quality-assured digital learning resources (a We Space).
 9. **Connect** – allowed students to find reviewed websites and online activities (Fig. 2).

The Ultranet's underlying technology was based mainly on Oracle and incorporated various Web 2.0 technologies. The Ultranet was thus intended to be a closed, secure place on the Internet, accessible by students, teachers, and parents from the school community.

The Department of Education and Early Childhood Development (DEECD)'s 2010 website noted that, specifically, the Ultranet was designed to:

- Enable parents to become full partners in their child's education, giving them online access to their child's homework, attendance, assessment, curriculum and teacher feedback at any time.
- Ensure that every child will have a complete record of achievement across all years of schooling.

- Give students their own online workspaces, personally tailored education programs, direct feedback from teachers and better access to curriculum.
- Enable students in remote schools to access specialised curriculum and podcast classes from schools that excel in various subject areas.
- Allow students to learn in an environment that will ensure that they have the cutting edge ICT skills they will need in the 21st century workforce.
- Reduce the administrative burden for teachers and schools by using the Ultranet for recording attendance, school reports, timetabling and school events, to pool schools' resources and give teachers access to a vast central database of classroom resources. (DEECD 2010a)

A major goal of the Ultranet Project was to improve communication between the school and its teachers with parents. In 2012, the Education Department's website announced that:

As a parent, the Ultranet will give you more detailed and timely access to information so you can monitor and support your child's learning. Information about your child and their school will build over time as schools progressively implement and use the Ultranet's many functions. In just a few clicks, you will be able to see your child's latest: attendance records, learning progress information, teacher feedback, in-class or at-home tasks and timetable. (DEECD 2012)

Development and Use of the Ultranet

In the mid-1990s Victoria set up a number of "Navigator Schools" whose purpose was to develop the use of ICT to improve both teaching and learning and school administration. In the early 2000s, Glen Waverley Secondary College, as a Navigator School, in a joint venture with Impaq Educational Services developed an effective school intranet that transformed the way the students and staff gained access to each other and to curriculum resources (Toomey et al. 2000). The Education Department was impressed that Glen Waverley Secondary College had provided: "an intuitive interface that seamlessly brings together various aspects of classroom 'business' (teaching and learning plus other associated administrative functions) into a single, central, logical environment that has a profound

Ultrahet, Fig. 2 “Spaces” on the Ultrahet (DEECD 2010a)

impact upon the way teachers, students, parents and other key staff share information and cooperate” (EduWeb 2006).

In 2005 the Ultrahet concept began to take life when the Education Department, building on the Glen Waverley Secondary College concept, commenced a joint R&D initiative with Oracle Corporation to produce “the prototype for a student centric system that supports teaching and learning, curriculum delivery and the management of knowledge in Victorian schools” (DEECD 2005). The prototype was to be

known as the Ultrahet and be based on Oracle technology. In 2006 to test the feasibility of these ideas, a “proof of concept” system was developed by the University of Melbourne and trialled in 22 schools over 18 months (Griffin and Woods 2006; Tatnall et al. 2013). The trial aimed to establish whether such a project was viable, to determine functional requirements, to identify any possible user and technical issues, and to investigate development and implementation costs. It was reported as a “proof of concept student-centric ICT system, called

Students@Centre, to support online teaching and learning, curriculum delivery and knowledge management in Victorian government schools” (DEECD 2010c). In 2006 the Victorian Government made an election commitment for \$60 million to build the Ultrahet (EduWeb 2006; Tatnall et al. 2013) and have it operational before the 2010 election.

The Ultrahet was launched in August 2010 when Victoria’s 1,500 State Schools were closed for an extraordinary student-free day for teacher professional development (DEECD 2010d). All 3,500 State School Principals and Assistant Principals were called to Melbourne to attend Ultrahet’s “Big Day Out” at the Melbourne Exhibition and Convention Centre to learn about the state’s new online learning network. Teachers across the state were asked to familiarize themselves with the Ultrahet from their own school location, but unfortunately the launch turned into a fiasco when the Ultrahet crashed disastrously at 9 am (Tatnall et al. 2013). Later when the system was running again, many teachers and principals experienced problems when they attempted to log on and reported it as running extremely slowly (Holden 2010; Levy 2010; Topsfield 2010).

Each Education Department Region appointed a number of “Ultrahet Coaches,” who were given 6 days of professional training and then based at a school. Their task was to service a small group of local schools with the goal of supporting teachers to prepare for the Ultrahet and to build ICT capacity in the classroom (DEECD 2009). As well as these coaches, each school was asked to appoint an “Ultrahet Champion” known as a “Lead User” who was provided with 2 days of professional training by the local Ultrahet Coach and given support materials and whose role was to offer ideas for school-based professional learning strategies and to promote use of the Ultrahet.

By 2012 the Ultrahet was well used by certain schools, centered mainly on a couple of country regions, both as a tool for student collaboration and as a means of communicating with parents. It had, however, not achieved the expected benefits for students, parents, and schools around the State, had a very low uptake by users, and had

not achieved the functionality originally intended (Victorian Auditor-General’s Office 2012).

DEECD has not fully considered the demand the Ultrahet would have on teachers’ time and workload, particularly in terms of teachers’ roles in supporting and guiding parents on how to use the Ultrahet . . . System problems have also discouraged uptake . . . These include the Ultrahet’s technical unreliability and poor performance, the lack of appropriate support to develop Principals’ and Teachers’ ICT competency and confidence, and ageing ICT infrastructure and devices (which can affect online access to the Ultrahet). (Victorian Auditor-General’s Office 2012: 30)

The original budget for building the Ultrahet was \$60 million, but this later turned out to be a very optimistic underestimate, increasing to three times this (\$180 million) before completion (Sharp 2013). DEECD claimed that an early evaluation pointed to positive teacher attitudes in the use of such an online environment but after that the adoption and use of the Ultrahet was much less than expected. Although it seemed like a good idea at the time with lots of possibilities to do worthwhile things, by late 2012 it was not being used to any great extent in most schools and was abandoned by the Government in June 2013 when DEECD signed an agreement with NEC that would come into operation in January 2014. The agreement was for NEC to continue provision of the Ultrahet, but only to schools that were prepared to use the service on an individual user-pays basis (Sharp 2013).

The Ultrahet and Technological Innovation

Any investigation of the adoption and failure of the Ultrahet must consider both its technical and its human components, and so this must necessarily involve a socio-technical research approach and methods. It is useful to consider the Ultrahet project as an example of technological innovation and to view it through the lens of technology adoption. Actor-Network Theory (ANT), or the “sociology of translations” (Callon 1986; Latour 1988, 1996; Law 1992), was designed to deal with socio-technical research in a way that would

address the need to treat the contributions of both human and nonhuman actors fairly and in the same way and was developed to analyze situations where separation of human and nonhuman elements is difficult (Latour 1993; Callon 1999; Tatnall and Gilding 1999; Tatnall 2000, 2009). It was clear from the beginning that the failure of the Ultrahet was not due to technology alone, and so ANT, and in particular Innovation Translation (Callon 1986), was used as a lens to understand why the Ultrahet was not adopted to the extent intended.

Innovation Translation sees the process of innovation in terms of translation (adaptation) from one state to another. Callon (1986) suggests that the process of translation has four aspects or “moments”: problematization, intersement, enrollment, and mobilization.

- Problematization involves one or more key actors that attempt to define the nature of the problems so as to be seen by other actors as having the answer (McMaster et al. 1997).
- Intersement involves interesting and attracting an entity by coming between it and some other opposing entity (Grint and Woolgar 1997).
- Enrollment occurs through a process of “coercion, seduction, or consent” (Grint and Woolgar 1997), and if all goes well, it leads to the establishment of a solid, stable network of alliances.
- Mobilization locks in as the solution proposed gains wider acceptance through some actors working to convince others (McMaster et al. 1997).

Failure of the Ultrahet

The problematization of the Ultrahet by the Government as a system to offer access to learning materials and to inform parents of their child’s progress seemed worthwhile to many when it was first proposed. What should have happened next was that considerable effort should have been put into convincing teachers and parents to accept this problematization and so

become enrolled. This, however, did not happen – there was a major failure of intersement!

An innovation is of little value unless it is adopted, and it will only be adopted if it can be adapted in such a way as to fill a need, that is unless it can be translated. In this case the Ultrahet failed to establish such a need. The problematization of the Ultrahet as “a student-centred electronic learning environment that supports high quality learning and teaching, connects students, teachers and parents and enables efficient knowledge transfer” (DEECD 2011a) was generally accepted, but teachers, however, were not entirely happy with all aspects of it connecting with parents and some saw this as a threat.

The first attempt to convince teachers of the value of the Ultrahet was at the “Big Day Out” and student-free day for professional development. This attempted intersement was a disaster that, far from convincing teachers of the Ultrahet’s worth, did exactly the opposite. Another attempt at intersement was the appointment of Ultrahet Coaches, but, in an informal conversation, one primary school principal indicated that the Ultrahet Coach who had visited them did not seem to understand the human issues involved in convincing teachers and parents to use the Ultrahet. The Coach was of the view that as DEECD had decreed that it be used, that was the end of it (Tatnall et al. 2011). This primary school had decided not to introduce the Ultrahet to parents until such time as there was something worthwhile on it for them to see – until it had some data about their own children. The Coach did not seem to understand this. In another failure of intersement, a parent of secondary schoolchildren pointed out that he had not been able to find out much about the Ultrahet and that as far as he was aware his children’s school was not using it. Clearly there should have been a good deal more done to convince principals, teachers, and parents of the Ultrahet’s value. The human aspect of promoting the Ultrahet was not given sufficient consideration.

The possibilities offered by the Victorian Education Ultrahet were considerable, but its uptake by schools was not. The solutions offered by the Ultrahet had value, but they were not

solutions to any existing problems that had been identified by schools or by teachers.

Underrepresentation of Girls in Computing

Therese Keane

Department of Education, Swinburne University of Technology, Melbourne, VIC, Australia

Synonyms

Girls in IT

Background

For many decades, females have been underrepresented in both the studying of computing and computing careers (Hoyle 1988; Varma 2010). As early as primary school, both male and female students are exposed to computing and are encouraged to use computers within their classrooms; however, as students progress to secondary school, gender inequality increases with age, and female students tend to not engage with undertaking computing classes (Larsen 2010). This is not country specific, but rather seen as a pattern in many countries including Australia, the United States, and the United Kingdom. By the time female students enter their final years of formal secondary education, the gender gap in the study of computing has widened deeply (Kirkpatrick and Cuban 1998).

At primary school level, students do not select subjects; rather they are exposed to a variety of

experiences and challenges. However, in secondary school and especially in the final years of schooling, students can elect the subjects they wish to study. The age of disparity has been identified at approximately 12 years of age, where there are gender imbalances in mathematics, science, and technology (Sáinz and Eccles 2012). The situation is more apparent as students enter their final years of secondary school and then university (Zagami et al. 2015). Typically, it is reported that the percentage of female computing students is approximately 20% (Falkner et al. 2015). These numbers are not high and raise concerns that are shared among teachers, academics, and computer professionals about the lack of female participation in computing subjects at both secondary school and tertiary level.

Globally

Computing is not a commonly sought-after career for young women. The problem is not confined or isolated to one continent, but on a global level; it is widespread across many continents – North America, Europe, and Australia (Deloitte 2016; Deloitte Access Economics 2016). The number of females graduating with a computing degree has consistently declined since the 1980s and now accounts for less than 18% of computing graduates (Hutchinson and Tadros 2014; NCWIT 2014). Typically, there are five times more men than women studying computing at tertiary level. These figures are replicated in the information technology (IT) industry where women currently constitute a small part of the workforce – 24% in the United States, 18% in the United Kingdom (UK), and 28% in Australia (Deloitte 2016; Deloitte Access Economics 2016).

Lack of gender diversity in this industry has implications for both society and organizations. There is increasing evidence that gender diversity in organizations has a positive influence on productivity such as higher sales revenues, more customers, and greater profitability (Herring 2009). However, the lack of gender diversity is due to the fact that it is very difficult to recruit capable and confident people with IT skills, particularly as the talent pool is restricted by the lack of qualified

women. Encouraging more women into university computing courses would lead to an increase in both the size and diversity of a country's skilled workforce and address the growing shortfall of computing professionals in industry.

Social Conditioning

Sociological factors are very important when explaining the gender differences in computing participation. From the early 1980s, computing has been seen as a subject that promotes isolation, abstract concepts, and activities reflecting masculine interests. Careers in computing have been seen as a masculine career that is associated with a high level of mathematical competence, low levels of social skills, and individual working conditions (Ensmenger 2015; von Hellens and Nielsen 2001). When this is combined with the absence of female role models and mentors, it is hardly surprising that females do not choose these fields of study.

Female attitudes to careers and work are shaped by family, friends, school, and more broadly society (Trauth et al. 2004). Family is the most powerful of influences. It has been widely acknowledged that parents (including guardians) encourage their sons to take computer classes and excel in this field of study; however, conversely, this is not the case with daughters. Historically, computers, computer games, and programming have been culturally perceived as a male enterprise (Klawe 2002; Willoughby 2008).

Female perceptions are molded by people close to them such as their mothers (Stockdale and Keane 2016). It has been known that mothers have shared horror stories they had in mathematics and science classes and negative issues they had with workplace computers. These stories tend to shape the attitudes of girls and thus the informal stereotyping that takes place within our society (Fiebig and Beauregard 2011). Female students are influenced by many people who are close to them, and this influence, whether it is positive or negative, impacts on their decisions to study computing. A mother's deep-seated gender-role opinions can have significant influence on the selection of their daughter's career choice (Bleeker and Jacobs 2004).

Careers in Computing

In addition to the influence of family and society, young females generally have a negative attitude to working in computing careers. Female students have little, if any, knowledge of the computing industry and the career opportunities within the industry. In fact, the computing industries themselves find it hard to describe what careers in computing actually are. Unlike other careers, such as teaching or medicine, whereby graduates become teachers or doctors, a career in computing is very difficult to describe and identify the likely vocation. Most people generally can identify one career in computing (such as computer programmers), and while there are many others, these are not well promoted or advertised. To further complicate this, there is an ongoing shift in the field, and the emergence of new or unknown jobs is being created which make it hard to keep up. This also contributes to the unattractiveness of the computing industry (Clayton et al. 2009).

Computer Games

From an early age, children are exposed to various forms of entertainment such as computer applications on tablet devices and electronic games such as Nintendo, PlayStation, and Xbox. Typically, games have always been more appealing to boys than to girls (Tomte 2008). Predictably, boys play video games far more than girls do. Some schools have promoted computer use through computer games which tends to be more attractive to boys than girls due to the competitive nature of the content (Willoughby 2008). However, other reasons have been attributed to the fantasy-based pretend play that attracts boys to gaming and girls' preference to reality-based pretend play.

Public Face of Computing

The world of computing seems to be almost exclusively male, spanning from the early humble beginnings to where we are today. Its public face is dominantly male; they are developers of computers, computer software, and social media.

For example, Bill Gates and Paul Allen from Microsoft; Steve Jobs and Steve Wozniak from Apple computers; H. Edwards Roberts from Altair 880; Mark Zuckerberg from Facebook; Jack Dorsey, Noah Glass, Biz Stone, and Evan Williams from Twitter; and Kevin Systrom and Mike Krieger from Instagram are all male. Many of these men are seen as visionaries, forward thinkers, and leaders. The dominance of male leadership in this context can be seen to reinforce a notion that this is not an area of activity where females are likely to find leadership.

Computers and Popular Culture

Computers have been portrayed through film, television, and literature since the late 1960s, such as 2001: *A Space Odyssey*. Typical portrayal of computers on film, literature, or television often shows males in positions of expertise or heroism, such as in the film *War Games* (1983). The simple premise of the movie is that the girl in the movie knows nothing of computers. At the end of the film, it is up to the boy and the programmer to stop a computer from blowing up the world. At the climax of the film, the simple logic of tic-tac-toes stops the computer from initiating nuclear Armageddon. The film portrays the kind of logical thought necessary to program and understand computers as being the exclusive province of men. Right from the outset, computer expertise in such popular entertainment is linked with males, not females.

Another example is Michael Crichton's book *Disclosure* (a movie was also made of this in 1994), where Crichton puts women in positions of great power in a Californian computer company; however, those with the expertise in computers are the men. Keeping in mind that this is a book with strong women roles, the two significant women are not shown as having computer expertise, that is, in this case, not possessing the technical aspects of computing in comparison to the male colleague who is made to appear that he is expert in all that is computing.

More disturbing than these examples, though, are portrayals in popular literature of women

using computers. These are more disturbing because invariably the female use of computers is portrayed as a woman's means of using a computer as a substitute for real life. In the *Batman Comic* series, Commissioner Gordon's niece Barbara turns to computers and adopts the identity of Oracle after she is crippled following a frenzied attack by a super-villain. Likewise, in the film *Copycat* (1995), Sigourney Weaver's character communicates through computers after being so traumatized following an attack by a psychopathic killer, that she is unable to venture outside. Similarly, Sandra Bullock's character in the film *The Net* (1995) is shown to have no other life than the one she works on with her computer. Working from home, with no friends, nobody knows who she is; she has no outside interest, no relationship, and no life. Even though at the end of the film she wins the day through her computer expertise, she still does not end up with very much in her life.

A further example comes from the television sitcom, *The IT Crowd*, which is set in an Information Technology Office in a large fictional British corporation. The show focuses on three members of the IT support team whose office is in a basement that is disorderly and shabby. Stereotypically, the two technicians do not have well-developed social skills and are not held highly by other people in the organization. While it is a parody, it reinforces the characteristics and attributes of people drawn to the computing profession.

Summary

The underrepresentation of girls in computing has been an ongoing problem for many decades. While there have been many studies examining why girls do not elect to study computing, a solution to this problem has not been found. There are many theories as to why girls do not study computing or chose not to enter the profession, such as the subject matter is not appealing or the industry is unattractive. The lack of strong female leadership as visionaries sends a strong message to young girls that computing is

not a domain for them. The popular media also reinforce this message through film and television by not having strong female leads who can competently use computers. Alternatively, other portrayals include satirizing attributes of people who are drawn to the profession such as those who lack social skills or prefer to work in isolation. While there is no clear solution, there are many stakeholders who are trying to address this issue, from curriculum writers in schools, to universities, to companies that are offering programs specifically targeted at girls, and to employers who are trying to make the industry enticing. While no specific program or stakeholder has been able to redress the underrepresentation of females in computing, much work and research have been conducted to understand the issues which have contributed to this problem (Butler 2000).

Using Social Media to Promote Academic Functioning

Michael J. Zickar

Bowling Green State University, Bowling Green, OH, USA

Social media has been used by organizations to sell products, to mobilize people politically, to share information, and to connect individuals with each other. Given the ubiquity of social media in our society, it is not unsurprising that academic departments and universities have turned to social media as a tool to connect with students, alumni, faculty, and other constituent groups.

Social Media Platforms

Different platforms have been used by universities. Facebook with its groups and pages functions has been more popular (e.g., Lawson et al. 2011; Zickar et al. 2018). Facebook groups and pages have been used to communicate with alumni (Farrow and Yuan 2011); to communicate information to students, alumni, and other constituent groups (Zickar et al. 2018); and to disseminate advice to first-year college students to help in their transitions (Russell et al. 2012).

Twitter and LinkedIn have been used by academics to develop networking opportunities (Donelan 2016) and to disseminate research to fellow researchers and to media (Mas-Bleda et al. 2014). Finally, academics have used a variety of social media platforms to teach additional content to college students (see Wankel 2010). Additional platforms such as Instagram and Snapchat are currently popular with undergraduate students, though there has been little research on how universities and faculty can use these tools to connect with students.

In addition to promoting academic functioning, social media can be used to help advertise academic programs and universities. Detailed metrics collected by social media companies can be used to advertise programs to targeted applicants. For example, using Facebook advertising, one could market a graduate degree in psychology to individuals in a particular geographic region who are within a specific age range who already have a bachelor's degree and express interest in psychology.

Individual researchers can use social media to make sure their research articles reach a larger audience than would be expected to read traditional academic scholarship. There are some academics who have built large followings on platforms such as Twitter, though research suggests that social media followings should not supplant traditional academic metrics for influence (Stewart 2015). These platforms, though, can help spread the impact of scholarly research and can help connect researchers who share similar interests.

Challenges Using Social Media to Promote Academic Functioning

Using social media to connect with students and other audiences has many challenges. First, user preferences change for various platform changes over time, and so it requires faculty and administrators to regularly learn new tools and platforms and to be sensitive to demographic-based preferences. In addition, social media platforms change their functioning on a regular basis, and it can take a lot of effort to keep on top of these technological changes. It is important that the person (or persons) who run a particular social media outlet receives periodic training on best practices, as those best practices change frequently.

In addition, to use social media effectively, new content must be posted on a regular basis. Finding and curating content can be a time-consuming chore for overwhelmed academics. In many cases, an account with out-of-date information may be worse than having no account at all, as the lack of updated content may connote lack of activity within the relevant academic programs. Additionally, concerns about privacy and regulation of user inappropriate interactions may dissuade some users from engaging in social media. Many of the social media tools include tools that can help monitor for inappropriate content as well as banning users who are abusive. A final challenge with using social media is differential access to platforms. Some individuals may not have the technology to engage in social media on a regular basis or may choose not to do so because of privacy concerns. Placing content on one social media site does not guarantee that the content will be seen by a large audience. One positive aspect about social media is that most sites provide detailed metrics on user engagement which can help guide its management and usage and help administrators find content that will be most engaging to relevant audiences.

Best Practices

To promote effective usage of social media, several best practices should be followed. First,

users should clarify their goals for using social media. Is it to build connections with alumni or to connect with undergraduate students or to attract new applicants or a combination of goals? Second, administrators should be trained on social media usage and receive periodic training. Third, multiple social media platforms should be considered based on the desired goals. Content should be geared to the specific features of each platform; identical content posted across different social media platforms is likely to be ineffective. Regular content needs to be collected, created, and posted. Finally, metric data provided by social meeting platforms should be analyzed to help determine the effectiveness of various types of posts and content. For example, on Facebook pages, it is possible to determine how many people have seen a particular post, as well as the amount of engagement (e.g., likes, comments, and shares) associated with each post. These data can be used to provide feedback on social media strategy and used to guide future activity.

Conclusions

Social media tools can be useful for academic units to promote additional connections with students, faculty, alumni, and other relevant constituency groups. Existing research has focused on using Facebook pages and groups to connect with alumni and students (Farrow and Yuan 2011; Zickar et al. 2018). This research shows that people who are connected to academic units on social media feel connected to their department. Research also shows that content must be targeted to a particular audience's needs. Different audiences will react differently to content tied more directly to them (Zickar et al. 2018). For example,

undergraduate students will react more positively to content highlighting their accomplishments, whereas alumni react more positively to posts featuring fellow alumni accomplishments. Clearly, more research needs to be done on using social media to promote academic functioning.

Value of Teaching Computer Science

Mary E. Webb

King's College London, London, UK

Introduction

Computer Science is the academic discipline that underlies all developments in Information Technology. A succinct but fairly comprehensive definition of Computer Science that reflects current understanding is “The scientific and practical approach to computation and its applications and the systematic study of the feasibility, structure, expression, and mechanization of the methodical procedures (or algorithms) that underlie the acquisition, representation, processing, storage, communication of, and access to information” (https://en.wikipedia.org/wiki/Computer_science). In recent years, reports from various countries have revisited the importance of all students learning Computer Science throughout compulsory education, following concerns about Computer Science being neglected in school curricula (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013; The Royal Society 2012; Wilson et al. 2010). These reports emphasized the serious implications for economic prosperity of the decline in Computer Science learning but also mentioned the benefits to individuals and society

of people being well educated in Computer Science. The decline in teaching Computer Science in schools has happened in many, but not all, Western countries and has generally been associated with a focus on basic digital literacy at the expense of the study of the academic discipline (Webb et al. 2017). All of these reports into the demise of Computer Science (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013; The Royal Society 2012; Wilson et al. 2010) recommended the learning and teaching of both Computer Science and digital literacy throughout compulsory schooling. Digital literacy enables people to use business applications such as spreadsheets and databases as well as to make safe and effective use of Internet-based technologies and thus enables people to be users and consumers of new technologies but not creators. Developing understanding and skills in Computer Science opens up a broad range of opportunities for creativity and innovation both for personal development and for employment prospects. Since these reports were written, many countries have reviewed and redeveloped their curricula, and there is generally a renewed focus on Computer Science (Webb et al. 2017). However, in the UK, for example, where a significant effort has been made to implement the recommendations of the Royal Society's original report (The Royal Society 2012), a recent report also by the Royal Society (2017) has found that the teaching of Computer Science in schools

is patchy and opportunities for learners to gain accreditation in Computer Science are still often limited. The main reasons identified for these problems were the lack of teachers qualified in Computer Science, lack of expertise to teach new courses, and limited access to appropriate professional development (The Royal Society 2017). In addition, concerns were raised about the qualification framework and the availability of good-quality research evidence regarding pedagogy. Therefore, the report has recommended very significant investment in teacher professional development on a level consistent with that in math and science education. Similar problems were identified by the International Federation for Information Processing (IFIP) Task Force on Computer Science in the Curriculum (Webb et al. 2015a, b). Thus, in most countries the teaching of Computer Science remains a significant challenge requiring substantial investment particularly in teachers. This article examines the arguments and reviews the evidence for the value of learning and teaching Computer Science in schools at various levels.

Rationales for Teaching Computer Science

The three main rationales for teaching computer science can be summarized as economic, social, and cultural (Webb et al. 2015b; Fluck et al. 2016). The economic rationale is well-known and frequently used to justify the need for Computer Science in the curriculum (e.g., see The Royal Society 2012). The economic rationale rests on both the need for a country to produce computer scientists to sustain a competitive edge in a world driven by technological developments and the need for Computer Science-enabled professionals in all areas of business and industry to support innovation and development (Fluck et al. 2016). The World Trade Organisation reported that in 2016, ICT was the fastest-growing category among commercial services other than travel and predicts that the future rise of new technologies will have a positive impact on digital trade (World Trade Organisation 2017).

In the UK, employers have reported an increasing need for computing skills (Employment, U. C.f., Skills 2014), and the UK together with the rest of Europe, as well as a survey of policies across most OECD countries, has described a “digital skills crisis” (House of Commons Science and Technology Committee 2016; European Commission 2017; Martin 2017). These digital skills are not just the basic digital literacy mentioned earlier but include programming and other computing skills that depend on Computer Science as the underlying academic discipline. While currently there is a need for basic computing skills, predictions of the effects of future technological development suggest the need for more advanced and creative skills, including the ability to innovate with technology, as a wide range of jobs become susceptible to computerization (Frey and Osborne 2017). Educating learners in Computer Science is therefore crucial for economic prosperity and is also an individual entitlement issue. Learners are entitled to have access to the “powerful knowledge” (Young 2013) that will enable them to take their place in society and enjoy good employment prospects.

The social rationale emphasizes the value in society of active creators and producers rather than just passive consumers of technology. Such capability empowers people to lead, create, and innovate with technology in society. Furthermore, understanding of the nature of Computer Science and how its applications, particularly in areas like artificial intelligence, may profoundly affect society, is important for people to be able to contribute to decisions about how new technological developments can best be harnessed to serve society and how their dangers can be avoided (Makridakis 2017).

The cultural rationale rests on enabling people to be drivers of cultural change rather than having change imposed by technological developments. Applications of Computer Science, including digital games, virtual reality, and augmented reality as well as the ubiquitous social media applications, have enormous potential for bringing about cultural change. At the same time, all of these technologies can be used to record and

preserve cultural traditions and influence how culture is portrayed and experienced.

In addition to these three major rationales for learning Computer Science, there are potential benefits for supporting the learning of other curriculum subjects and education more generally as will be discussed next.

Computer Science Supporting Education

There are many ways in which understanding and skills of Computer Science may support learning and education in other curriculum areas. These possibilities range across (1) understanding how Computer Science may support knowledge generation in many different subjects, (2) using programming and modelling skills to support learning about systems and phenomena in subjects such as science and geography, (3) using problem-solving skills gained in Computer Science to support problem-solving in other areas of the curriculum, and (4) using Computational thinking, developed in Computer Science lessons, to support learning in a range of subjects. Possibilities 3 and 4 remain controversial as discussed later in this article.

Computer Science has increased in importance for knowledge generation in a range of important areas of human endeavor, including areas as diverse as healthcare (Kunkle et al. 2016) and agriculture (Janssen et al. 2017). Thus, Computer Science is heralding new developments and is providing new methods for knowledge discovery (see, e.g., Adam-Bourdarios et al. 2015). Thus, understanding how methods of Computer Science, including big data and analytics, artificial intelligence, modelling, etc., are enabling knowledge generation is important for empowering learners to critically evaluate opportunities for new knowledge generation across many subject areas, especially in science and social science. There is also value for learners of actually engaging in the types of processes employed by scientists in order to understand how knowledge is generated (Evagorou et al. 2015). Increasingly such processes employ computer-based modelling and/

or big data analytics (e.g., see Janssen et al. 2017).

There is a long history of research into the potential benefits of learning programming for developing general thinking and problem-solving skills, but the findings of the earlier research were variable and inconclusive (see, e.g., Salomon and Perkins 1987). The key issue is whether or not transfer of such skills occurs between one context and another. Transfer of skills between disciplines and even between topics within a discipline is not automatic (Scherer 2016), and Salomon and Perkins (1987) explained the variation in results of earlier studies of the transfer of problem-solving skills from learning programming by whether or not “mindful generalization” had been employed as a pedagogical strategy. However, they also questioned whether or not programming was the best approach to develop general problem-solving skills. While there is conceptual overlap between programming skills and general problem-solving skills, there is a need for further empirical studies to examine transfer in current educational scenarios with the new generation of languages and tools for learning programming (Scherer 2016). The issue remains controversial, and the debate has been enlivened recently by the revised focus on computational thinking (Grover and Pea 2013; Lye and Koh 2014).

Computational thinking is about analyzing and solving problems and presenting solutions in such a way that they can be implemented on computers. According to Wing (2006), thinking in this way is so fundamental in the digital age that computational thinking should be regarded as another basic skill set alongside literacy and numeracy. While computational thinking does not depend on programming, Webb et al. (2015b) argued that computational thinking is best developed through Computer Science learning including programming since (1) the processes of computational thinking, for example, abstraction and decomposition, are also fundamental to Computer Science; (2) programming, especially with visual languages, makes an excellent vehicle for students to explore the concepts in a concrete way, and (3) implementing the concepts in a program provides a means for students

to check their thinking. As their expertise in computational thinking develops, students would be expected to use their skills and build their understanding of applications of computational thinking via a range of examples across different subjects. Thus, if computational thinking is to be developed through learning computer science and the claim of universal benefit (Wing 2006) is accepted, then it is possible that a significant value of learning computer science may be to develop computational thinking. However, the claims for computational thinking remain controversial. While there is no doubt that experienced computer scientists engage in computational thinking in order to design computational models and algorithms that can be used for computational solutions to problems, according to Denning (Wing 2006), the way in which computational thinking is defined in the literature remains a source of confusion. The nature of computational thinking, its value for students' learning, and methods of assessment are currently the subject of ongoing research.

Overcoming Barriers and Limitations to Learning Computer Science

Thus far, this article has argued for the value of learning Computer Science as an entitlement for all learners. Nevertheless, as many have argued, many Computer Science concepts can be difficult to understand. Furthermore, programming, which is considered an essential element of introductory Computer Science courses, is generally considered to be difficult to learn (see, e.g., Robins et al. 2003). Some, in Computer Science education, have therefore questioned whether it is appropriate for all young people to learn Computer Science. However, most educators would agree with Bruner that any subject can be taught to any learner at any stage in their development (Bruner 1960). It is a matter of simplifying concepts, using concrete examples, and revisiting ideas regularly in a spiral curriculum. Recent developments in visual programming

languages and other tools that support learning of programming as well as new pedagogical approaches, such as "CS unplugged," are making Computer Science more accessible to younger learners (Duncan et al. 2015).

Conclusion and Implications

In summary, the arguments outlined here present a strong case for students to learn Computer Science in schools. Developing the understanding and skills of Computer Science is an entitlement for all school students that will support them in taking their place in society, influencing cultural change and potentially supporting their employment prospects. Furthermore, economic prosperity depends on a workforce that is not only digitally literate but is also able to create and innovate with technologies within both the computing industry itself and across all areas of business and industry. At the same time, individual learning across many curriculum areas may be supported by understanding and skills developed in Computer Science. Whether this support for other curriculum areas is focused on the value of Computer Science for knowledge building and using programming and modelling skills or whether for the even broader value of developing computational thinking and problem-solving ability remains a subject for further research. Furthermore, enabling all students to learn Computer Science may be challenging and needs to be supported by more research into which pedagogical approaches are successful with which learners.

Value of Teaching PRINCE2 Project Management Methodology

Angela Lecomber

See Differently, Malvern East, VIC, Australia

Synonyms

PMBOK; PRINCE2; Project management; Training

Introduction

As project management evolves as a field of practice, companies are now realizing that their entire business, including most of the routine activities, can be regarded as a series of projects. Simply stated, businesses are managing their transformations by projects.

There are a number of accepted approaches to project management, the Project Management Body of Knowledge (PMBOK) and Projects in Controlled Environments Version 2 (PRINCE2) being two of the most important. Recently there has been considerable interest in Agile Project Management.

Joslin and Muller (2015) found that there was a positive relationship between the use of project management methodologies such as PMBOK and PRINCE2 and project success. These are described as project management “best practices” by the respective “owners” which are the Project Management Institute (PMI) and AXELOS, respectively.

The teaching and learning of project management have attracted the attention of many scholars within project management professional education (Ojiako et al. 2015). There are a number of issues with the teaching of project management specifically to IT professionals which was described by Lecomber and Tatnall (2014). The authors made the distinction between education and training of project management. The fundamental difference between education and training

is that in education, the focus is to provide learning that lasts. “Education can be described as what remains after one has forgotten what one has learnt in school” (Albert Einstein). However with training, people are shown what to do rather than really ensuring that they understand the underlying theory. Training does not allow for reinforcing, monitoring, and encouraging which are necessary to ensure that real learning is acquired. With training, there are limitations in the way in which courses are delivered on learning outcomes.

This entry does not distinguish between education and training but seeks to communicate the value of teaching a particular project management methodology, PRINCE2.

PRINCE2 Project Management Methodology

PRINCE2 is a methodology for managing projects and has grown to become a de facto “standard” as a project management method in more than 150 countries worldwide (Sargeant et al. 2010). PRINCE2 was originally developed for the UK government to manage their IT projects and was based on soft systems methodology. The first version of PRINCE was published in 1989 (Sargeant et al. 2010).

A multidisciplinary research team from the Queensland University of Technology (QUT), financed by the former owners of the intellectual property of PRINCE2, the Office of Government and Commerce (OGC), undertook one of the first empirical studies into the impact of the PRINCE2 methodology on project performance (Sargeant et al. 2010). The research study was entitled “Creating Value in Project Management using PRINCE2” and also conducted parallel research on the impact of other unspecified (non-PRINCE2) contemporary project management methodologies.

The researchers interviewed PRINCE2 practitioners from a diverse range of industries (including Information and Communications Technology, Construction, and Transport) and across three major geographical regions (the

United Kingdom and Europe, the United States, and Australia) (Sargeant et al. 2010). The researchers found that PRINCE2 was perceived as a very robust, comprehensive, and pragmatic project management framework (Sargeant et al. 2010).

Problems and issues which impeded the adoption of PRINCE2 to projects were organizational and not methodological, and the dominant issue identified by participants was poor project sponsor/board performance and a reflection that organizations either do not know how or do not possess the commitment to properly implement PRINCE2 (Sargeant et al. 2010).

Wells (2012) explored the effectiveness in the workplace of project management methodologies including PRINCE2. Her research found that there was “a chasm between the intended strategic directions of the project management methodology and its actual contribution to projects, managers and their teams” (Wells 2012). According to Wells (2012), the purported benefits are often not realized or can have unintended consequences at the project level and adversely affect project success.

Furthermore, Wells’ (2012) research on project management methodologies showed that the methodologies were useful for those that were at opposite ends of experience and accountability for projects:

- The inexperienced in project management
- Those who were most senior in the organization who were focused on the governance of projects

In between these two ends of the spectrum, the “perceived benefits and advantages of using project management methodologies dramatically falls, to a minimum, corresponding to the middle ground of the range of perspectives”(p. 57), the drop largely due to the drawbacks and limitations that the practitioners experienced in adopting the methodologies (Wells 2012). In other words, those who had some experience of project management considered the use of a project management methodology to be an overhead in their day-to-day work and did not use it. It was only

useful for those who were inexperienced as it was a useful guide for them. It was also valuable for those very experienced who were also senior managers as they were looking for ways to control projects and implement governance across the organization by seeking a standard in delivering projects (Wells 2012).

Research Study: Longitudinal Case Study

A research study was conducted by Lecomber (2017) to understand how participants used and adopted the PRINCE2 methodology to workplace projects following a professional training course. The study, over 2.5 years, used case study as a method. The research formulated qualitative answers to the main research question: “How are practitioners influenced to apply PRINCE2 in complex and dynamic environments?”

The research focused on studying 16 staff across a broad range of departments within an organization from sales to IT. The results showed that there were some participants who adopted as much of the PRINCE2 methodology as they were able for their work projects and actively sought to improve their practice. Another group of participants had knowledge of the methodology but considered the overhead in using it far outweighed the benefit derived from using it.

To analyze these two different forms of adoption, Innovation Translation, informed by actor-network theory (ANT), was used. ANT enables the researcher to think in terms of different translations and to seek to identify the actors involved and the interactions that formed possible stable networks supporting those translations. Innovation Translation has the advantage of being able to explain examples of partial adoption and of situations where what is actually adopted differs from what was proposed (Tatnall 2009). This was particularly relevant for this study as it could be said that one group of participants made *only* a partial adoption.

ANT, also known as the Sociology of Translation (Callon 1986; Latour 2005), was developed by science and technology scholars

Michel Callon and Bruno Latour, sociologist John Law, and others. It is a conceptual framework for exploring collective socio-technical processes and aims to follow the actors in a given network in the process of new network formation (Latour 2005). Innovation Translation, informed by ANT, argues that an innovation moves along as a chain of consequence by energy given to it by everyone in the chain whose actions shape the innovation to suit themselves (Tatnall 2009).

Actors Involved Even Before Delivery of the Training

The actors involved include the trainer, trainee (learner), curriculum, and the workplace. There are actors at play even before Day 1 of the training course. These are AXELOS, the Examination Institute (APMG), and the Accredited Training Organization (ATO). The ATO provides the training material and the trainer. The ATO obtains the PRINCE2 manual from a bookseller who procures this from AXELOS, while APMG dispatches the exam paper. The nature of the outcome of the training experience is a result of the interaction of the human actors (the trainer and the other participants) and nonhuman actors (training materials, timetable, exam papers, PRINCE2 manual, and training venue). After the training, the participant project manager seeks then to adopt the innovation in the workplace. This research study seeks to understand both the interactions that occur during training as well as in the workplace after the training course with respect to the adoption of the PRINCE2 methodology.

Understanding Adoption in Terms of Translations

Callon (1986) defines four moments (stages) of Innovation Translation: “problematization,” “interessement,” “enrolment,” and “mobilization.” The four stages, if successful, lock the actors into the network and create a stable translation (Davey 2014). This research looked at adoption in the form of two different translations:

1. Some participants adopted as much of the PRINCE2 methodology as they were able for their projects and actively sought to improve practice. The study named this adoption as

the Performing Translation (**PT**). Those who had adopted **PT** had a focus on continuous improvement in their practice. Those who adopt the **PT** are people who keep attempting to apply their learning and hence learn more. In addition, those who adopted the **PT** conducted their own research into “best practice” outside of work hours.

2. The other group of participants who had knowledge of the methodology but considered the overhead in using it far outweighed the benefit derived from using it formed the Knowing Translation (**KT**). A **KT** sees nothing in the formal structures of PRINCE2 that is so valuable that they would sacrifice early delivery by going through procedures stated in the methodology. Those who had adopted the **KT** would only apply what they had learned to the workplace if they perceived adoption across the organization.

In the case of **PT** participants, as their organization did not have the supports such as strong leadership for using a methodology and a strong Project Management Office (PMO), some participants who adopted the **PT** eventually resigned from the organization. In this research study, the PMO was weak and could not enforce the governance needed to support the use of PRINCE2.

Participants whose form of adoption was the Knowing Translation (**KT**) had knowledge of the project management methodology but considered the overhead in using it far outweighed the benefit derived. The lack of support from the top-down commencing with the senior leadership team and the original sponsor of the methodology had a strong influence on those who adopted the **KT**. A senior leadership team and sponsor must go beyond paying “lip service” to the methodology and actively comply with the methodology in terms of behaviors, responsibilities, and expectations of their role on the project as sponsors and project board members.

Implications

The research results by Lecomber (2017) identify two adoption outcomes as a result of

project management training which could be used to assist organizations in their strategies to support embedding of learning outcomes following project management training. These results are congruent with the research conducted by the Sargeant et al. (2010) study which showed that problems and issues which impeded the adoption of PRINCE2 to projects were organizational rather than methodological.

The value of professional vocational education and training in project management depended on what structures were in place in the organization to support the adoption of the project management methodology. These supports include:

- A strong Project Management Office (PMO)
- Senior leadership team that supports the use of the methodology
- Strong visible support by the sponsor of the methodology

Conclusion

In the study conducted by Lecomber (2017) which was based on PRINCE2, the emergence of two possible adoption outcomes has implications on how organizations derive value from their investment in professional project management education and training regardless of the methodology used. As well as ensuring that the project management education is performed well, it is important that organizations commit to supports in place such as a strong PMO, senior leadership supporting the methodology, and strong visible support from the sponsor if the organization wishes to derive the value from the project management training. Otherwise the investment in teaching project management is a “waste of money.” This is particularly important in the education of IT professionals.

Introduction

Technology-enhanced feedback to students comes in many forms now that technology has become immersed in all aspects of the educational

process. Higher education institutions are criticized by students for the poor feedback practice (Boud and Molloy 2013), yet they, like other educational organizations, have access to video-enhanced feedback through the use of mobile devices. This chapter describes how video captured on mobile devices can play a part in a video-enhanced feedback process. The chapter is organized in three sections. First, video feedback in schools and higher education, then the processes employed in video-enhanced feedback, and finally the management issues related to the use of video to enhance feedback.

Video capture technologies are now readily available and have a broad acceptance among students and are accessible to educators worldwide. This chapter describes the use of video-enhanced feedback to build on the idea that it offers a richer format than audio and written feedback alone (McCarthy 2015). This has implications for practitioner across all contexts of education. In addition, this chapter focuses on the use of video in the feedback process because feedback has been clearly identified as having an impact on educational outcomes (Hattie and Timperley 2007) across all sectors. There are different forms of technology that are being implemented and made available to educators across the sectors, and mobile devices are becoming part of strategic planning in some jurisdictions and context.

Video Technologies in Schools and Higher Education

The type of technology (mobile, desktop, tablet) used is dependent on the educational context. Assessment feedback in primary education would typically use different technologies to those being used in secondary and tertiary education. Technologies available in most school settings within Australia include some form of commercial learning management systems (LMS) and/or commercial products, such as those found on the app stores, and bespoke practitioner generated systems.

Learning management systems are available to schools and higher education institutions.

They provide their users with multiple opportunities to engage in feedback and engage with multimedia tools such as video. Learning management systems also provide their users with a level of security and system-wide support which is a critical component to ethical educational practices while enabling a community of practice within which students and teachers can operate because of the stability it provides to the learning environment. A number of plug-in solutions that allow users to incorporate video into these learning management systems exist although it's only relatively recently that these add-ons have allowed for a video to become part of the assessment feedback.

In addition to the learning management systems, there are a plethora of commercial products sitting outside the scope of the educational institutions. These products are often heavily marketed into the educational space and provide users with opportunities to enhance their feedback practices and can include video. These enhancements often come at the cost of the practitioners' time, effort, and financial commitment because these systems sit outside of the supported learning environment promoted by their institution. Commercial feedback products can now be found for all types of systems such as Windows, Macintosh, and UNIX, but few have video as their central evidence point. They can also be found in the major application stores for mobile devices. The trouble here for practitioners is that these systems have mobile versions as well as desktop versions and that the versions change as improvements are made.

The final type of technology available to enhance video feedback is a bespoke system that may be generated from and by practitioners in the field. These systems are often research based, poorly supported by the institution, and require effort to overcome barriers of acceptance (Boud and Falchikov 2005). As such these are rarely implemented at a system level and rarely face the rigor of commercialization. These investments are unique, and while driven by practitioners who have an intimate knowledge of their feedback assessment requirements, they represent a small minority of the systems currently being used to

place a video in the feedback and feedforward assessment process.

Processes of Video-Enhanced Feedback

Sitting within this context is the complex task of integrating video into student feedback opportunities. One of the key drivers of this particular task is the idea that when students are empowered and can reflect openly and freely in a risk-free environment, they will generate a clear understanding of their progress toward their learning goal. The word empowerment is often synonymous with the word personal and ownership. These two concepts relate directly to the use of mobile devices. Mobile devices are often a personal device of an individual and customized by the individual to meet their particular needs. Information kept on this device is, therefore, personal, private, and accessible only to those people that the individual chooses. This allows the user to maintain ownership. The use of these devices for feedback processes can be a powerful tool if the student understands and accepts the positive learning outcomes that can be achieved through their use.

The increasing capabilities of video-enabled devices in terms of storage of material, connectivity with other devices and advancement in camera and voice recording capabilities, make them an opportunity for the enhancement of feedback in the learning and assessment process. This leads to exploring how tablets, phones, and personal wearable equipment might be used to enhance the video feedback process for students.

Exploring video technologies and their enhancement requires a framework for discussion of the video feedback process. Figure 1 shown below is one such framework.

The diagram identifies two key players in the feedback process. The educator and student are both involved in different ways within this process according to the image. This image is drawn from research around teacher education but is being adapted here to guide discussion about the place of video. The two lines in the diagram represent the two individuals involved in the

Video-Enhanced Feedback, Fig. 1 Video-enabled dialogue process (Dann and Dann 2018)

process. The lines start in separate places to represent the “gap in knowledge” which is the intended learning goal. The individuals’ paths cross at times when they speak or communicate about what they have seen or done depending on the perspective. This is called the point of reflective dialogue (Dann et al. 2018). If we use video and allow students to collect video to enhance this reflective dialogue, a number of issues arise which will be discussed further in this entry. Essentially, a student may be collecting video evidence of practice, demonstrating knowledge and performing skills while the educator is observing, documenting, sorting, and aligning information to the intended learning outcomes. Traditionally students receive information in text or voice recording formats, but now with the influx of technologies such as mobile video-enabled devices in the learning environment, it is common for students to be observing collecting and sorting through information collected or viewed on their mobile device about their learning. This is now part of the dialogue between themselves and the educator working with them. This new information is in the back pocket or hands of the student and the educator. This offers increased accessibility to the video of the student performance tasks, thus increasing the opportunities to discuss the contents of this video in order to reduce the “gap in knowledge” that the student has.

Processes of Technology-Enhanced Feedback

Video use can be supportive of the learning environment in this new age of mobile devices. There are a couple of key issues to consider. Firstly, the purpose of the assessment and the role students are given during the assessment process become central to the success of any feedback. As mentioned earlier, assessment types such as essays and tests do not lend themselves to the use of video, particularly video captured on mobile devices. A video is more engaging when used in performance-based activities. Secondly, there needs to be a clear link between the learning outcomes of the assessment and the possibility of seeing and providing formative feedback to students through video captured. This link between performance and learning outcomes needs to be understood by both students and educators (Bennett et al. 2017). Once there is a clear link, the third issue is the need for structured and systematic processes that link the assessment activity and any subsequent video of activity directly to some of the assessment criteria. This provides information for the students to share with peers and their educator/teacher. This raises the question as to whether or not the student viewing themselves or their peers have the knowledge base to provide clear definitive commentary about the

success or failure of the student attempting to demonstrate some skill or knowledge.

When learners are empowered to participate in their learning and strive for excellence in their assessment through a culture that develops assessment literacies, mobile devices can play a role. Capturing video evidence with a mobile device is only part of the process if the assessment task has components of performance and/or demonstration of skills and knowledge. The figure above shows a gap in knowledge that is initially set up by an assessment task. This gap is represented by the learning goal. The learner and the educator come together and discuss their understandings and perceptions of the task and the demonstrable skills that will indicate progress towards the goal. Once this event has occurred, the learner is then able to observe others and have peers observe themselves and record this activity with video captured on a mobile device as part of this process. The next time the learner and educator come together, the video can become a valuable piece of evidence for both to view and discuss. The discussion of the video increases the potential for the learner to identify unseen or unknown actions and behaviors (Dann and Allen 2015) and also allows both student and educator to explore actions and opportunities for increased performance. This ongoing action planning informs the dialogic conversation.

Using video changes the dialogue between learner and educator. It introduces a reference point that would normally have been the written observations or images of the lesson and, at the worst, memories from the performance without supporting annotations. Each of these types of evidence requires the educator to respond and guide the student toward the learning outcomes. The words and actions of the student within these videos can now be examined by both the educator/teacher and the student. This connection can become the model for peer-to-peer engagement with other video evidence in their attempts to improve.

The space between the educator and the learner after the dialogue is critical for both to reflect and consider their ongoing attempt to achieve their learning goal. There has been significant work

conducted in the peer feedback space (Ajjawi and Boud 2017) and the increased emphasis on student satisfaction and the personalization for learners in education (particularly higher education) due to the preference of students for this over general feedback (Cramp 2011). This brings the use of personal devices into the scope of educational support tools. Building opportunities to engage learners with their practice and model good coaching and networking practice and strong dialogue between learner and educator can be enabled and enhanced by the use of video captured on personal devices.

Further research has shown that actively engaging with the videos through reflective practice can also improve learning outcomes for learners in higher education. This engagement can be through viewing and discussing, viewing and coaching methods, viewing in personal reflective quiet spaces, and also viewing, editing, and adding reflective commentary to the video file. The increased number of video editing systems freely available to students further enhances the possibilities and value that video can add to the formative assessment processes and even the summative assessment process.

One key to the effectiveness of the video use is the alignment of the video to the learning outcomes and the structures provided by the educator. Structure equates to processes and procedures for users. The use of video requires structure around what is videoed, to ensure that the video content is relevant to the learning. Structure in the process of time and volume of collected video to ensure participant acceptance of the video capture. Finally, due ethical considerations require a structured approach to account for how to work with video that might include a vision of others. Each of these elements requires the attention of educators who plan on using video-enhanced feedback captured on mobile devices.

The mobility of the device brings with it many ethical dilemmas for the educator who is choosing to engage with the opportunity. These dilemmas include the immediate storage of the video, the security of this storage, and the access to the video. The use of personal devices by a student overcomes many of these ethical issues until

others are included in the video that is captured. When others are involved, then there are a number of issues to be considered regardless of your activity being research or purely for personal assessment and learning. It is important to note that a student may have different views of video use to the teacher and the teachers' ethical responsibility is to manage these views. These ethical issues relate to the privacy of individuals, and these differ depending on the location of the video capture. Be aware that privacy now relates to the analytics of student use and access (Pardo et al. 2017). Specific ethical requirements from the institution about the following aspects should be sought prior to instigating research into mobile video capture for enhanced feedback.

The Storage Requirements of the Video

Mobile video captured is often stored directly on the device, but some individuals have automatic cloud-based backup, and each device has options for the storage of the video. Particular attention needs to be given to the storage of video on cloud servers as these have various access and ownership policies that are important considerations. As an example, Australian researchers collecting video in Queensland are not able to have any data stored on servers outside of Australia. This means that the common cloud servers attached to major brands such as Apple, Samsung, and Nokia need to be explored if the video is going to be stored on these servers.

The Transmission Requirements of the Video

The capture of video on devices is a simple process, but the length of video collected and the resolution of the video capture device has a direct impact on the files size created. The file size may impact on how you choose to store and/or share the file. If you are choosing to share the video over an open-access Wi-Fi environment, then you will need to consider the security and access to that environment. Departmental wireless environments are typically locked down to accredited users, and therefore protocols are already in place for those who may access the video. If the device is a personal one and is not connected to a

systemic environment such as a department or an organisation, then consideration may be required as to how to transmit the file(s). Transmission over open telecommunication networks can be quick and are less secure than those previously described. These issues require consideration if you have private information or the video contains vision of children or other material considered sensitive.

The Security Over the Video Access

Once the video is stored, access to it needs to be controlled by the creator. General access to private devices is often controlled by the owner of the device and this can vary. Bluetooth access and access to the device by others need to be considered dependent on local requirements. Generally, this would not be an issue, but depending on the scale of the use being sought, this still needs consideration. Key to this issue is the scale and systematic implementation of the video process. Placing a personal device in an assessment process requires the educator to have a clear vision of the processes and products that might be created and how the learner and other learners will interact with these.

The Requirements of the Location in Which the Video Is Being Taken

When discussing location in our localized world, we need to be conscious of the numerous locations that might be involved. Online coursework or even on campus coursework can involve any number of locations. The authors' work was positioned within teacher education which involved the classrooms at schools and spaces within the university. Implementing a program of mobile video in a teacher education context or even a nursing or science program may involve learners going off the grounds of the university to visit and learn. In this case consideration of the local hardware and software requirements needs to be considered. Some sites may have a strong secure Wi-Fi environment, while others may not, and this could result in difficulties for learners who cannot undertake the processes set up by the educator. Further to this is the need to understand the ethical

and organizational constraints of the learners' new environment. Some organizations may only allow video to be collected by their own organizational approved and linked devices and may not allow personal devices in any form.

Each of these ethical issues needs consideration to embark on a mobile video collection program for increasing dialogue between educators and learners or even between learners. The movement to mobile devices has challenged educators and will continue to provide conundrums for educators and learners as the functionality changes and advances. Video capture on mobile devices has been shown to play a role in the feedback and assessment literacy of learners, but the systematics and protocols of the educator and their respective organizations need to be clearly articulated and understood.

Conclusion

Video-enhanced feedback is a phenomenon that is constantly changing and requires educators to maintain the currency of practice and to explore the evidence-based research that exists in order to ensure quality learning outcomes. The role of the educator is to ensure a balance between the demands of the students and the resources available to the educator. If this balance is achieved within a holistic view of the learner, then it is very possible that video-enhanced feedback will enrich the learning of students who are able to engage in this practice.

WalkAbout Framework for Contextual Learning Through Mobile Serious Games

Fernando Almeida

Polythenic Institute of Gaya, University of Porto
& INESC TEC, Porto, Portugal

Synonyms

Contextual learning; Mobile learning; Technology enhanced learning; Ubiquitous learning

Introduction

Mobile technologies are increasingly being incorporated and disseminated in education. Their resources promote social interactions and communication facilities due to Internet connectivity and other programs that can be used in the teaching and learning process. These new technologies associated with the processes of collaborative learning stimulate the classes, encouraging the students to think through the interaction between them and the teachers in the resolution of challenges and problems (Fojtik 2014).

Mobile devices such as smartphones, tablets, and other gadgets can be used anywhere and offer many applications and features that allow interaction and communication between users. One of

the applications that can be used with these devices is the mobile educational digital games (Parise and Crosina 2012). These games have a high amount of content and different levels of challenge that promote the intellectual development of students.

Mobile educational games when used in a collaborative learning approach can streamline the teaching process. According to Laamarti et al. (2014), the inclusion of collaborative activities with the application of mobile games improves acquisition and knowledge and fosters the development of various skills such as self-learning, problem-solving skills, critical capacity improvement, and socialization.

Collaborative learning assumes that the construction of knowledge is carried out by means of social interaction, contributing to the development of social skills and also enables greater involvement with content, exchange of ideas, and formulation of new perspectives. According to Le et al. (2018), using the collaborative methods of teaching the student becomes active and participatory in the learning process, making him assimilate concepts and information, facilitating the construction of knowledge through interaction with other individuals.

Despite the unequivocal advantages associated with the adoption of mobile educational games, several challenges must be considered to create contextual learning experience. Several research questions emerge as relevant, such as:

RQ1: How can we create immersive learning environments?

RQ2: How to facilitate the interaction with the natural environment?

RQ3: How can we facilitate the interaction between students?

RQ4: How can we transmit the feeling that the user is controlling their games?

RQ5: How can we assure that the game is effectively helping students in their learning process?

In this sense, this study presents a novel framework and associated learning process to produce contextual learning mobile game systems that look and respond to the identified issues above. This entry is organized as follows: initially a literature revision on serious games, contextual learning, and mobile learning is performed. After that, the adopted methodology is presented. Consequently, the results of this study are analyzed and discussed. Finally, the main conclusions are drawn.

Serious Games in the Learning Process

Game-based learning uses gaming as a tool for students to engage in learning while playing. According to Prensky (2013), learning based on digital games is based on two premises: (i) students have changed their way of searching and acquiring knowledge and (ii) these individuals are from a generation that grew up experiencing games, such as computer games and video games. This new form of entertainment shaped preferences and abilities, and offered enormous learning potential for both children and adults. Game-based learning drives innovation through education, hence the importance of engaging a broad community as educators, designers, programmers, researchers, and students at all stages of the process and implementation of this approach (Bakan 2018). Serious games have been successfully adopted in different domains of education, such as management, entrepreneurship, computer science, or languages training (Almeida 2017; Alyaz et al. 2017; Buzady 2017; Yassine et al. 2017).

By using games for educational purposes, various aspects of the learning process are supported. Students are encouraged to combine knowledge from different fields to make a decision or choose a solution among several options; students can choose how the outcome of the game changes based on their decisions and actions and, ultimately, they are encouraged to interact with other team members, discuss and negotiate subsequent steps, and thus improve their social skills (Buzady and Almeida 2019; Foster 2011).

Panisoara et al. (2015) state that one of the key aspects of effective learning is motivation, which needs to be sustained through responses, reflection, and active involvement in order for learning objectives to be met; it is important to have a balance between an exciting game path and properly completed learning. The players have to feel realism, challenge, opportunity of exploration, and control. According to Bawa et al. (2018), multiplayer games are one of the most powerful forms of motivation, enabling group replication of situations and conflicts under different conditions and configurations.

Contextual Learning

Context can include many aspects or dimensions, such as location, date, time, personal and social activity, resources, and goals and task structures of groups and individuals. Context-aware computing has established a variety of context definitions, mostly starting from location or object context. Johnson (2002) advocates that contextual learning and teaching is based on the discovery that students find meaning in their schoolwork when they join the content of academic subjects with the context of daily life. Zimmermann et al. (2007) give a pragmatic definition of context. For them, context of a person or an object can be defined by five distinct parts:

1. Identify context – includes information about objects and users in the real world. With respect to users, their profile can include preferences, acquired-desired competences, learning style, etc.

2. Time context – ranges from simple points in time to intervals and a complete history of entities.
3. Location context – splits into quantitative and qualitative location models, which allow working with absolute and relative positions.
4. Activity context – reflect the entities goals, tasks, and actions.
5. Relations context – captures the relation an entity has established to other entities and describes social, functional, and compositional relationships.

Contextual learning has the power to help student's process, because new information that is given to them in a way that makes sense according to their own world of memory and experience (Suryawati and Osman 2017). The importance of this type of learning is that the student's mind naturally seeks meaning and context in the subjects they are being taught. Therefore, Rosa et al. (2017) state contextual diversity facilitates the learning process. At the same time, this type of learning can occur in a number of different places: in the classroom, a laboratory, a computer lab, outside, or in a place of work (CORD 2001). Due to the flexibility of this type of learning, a teacher can design a learning environment, which incorporates many different forms of experience, including social, cultural, and psychological.

Mobile Learning

There are various definitions of mobile learning but no one is generally consensual. Dewey (1996) was the first one to address this issue and defines mobile learning as “a society which is mobile, which is full of channels for the distribution of a change occurring anywhere, must see to it that its members are educated to personal initiative and adaptability.” Ally (2005) defines mobile learning as “the delivery of electronic materials on mobile computing devices to allow access from anywhere and at any time.” More recently, Basak et al. (2018) advocate “m-learning is the subset of e-learning through mobile computational devices.”

Commonly mobile learning has often been viewed as learning mediated through mobile technology. Due to the progress in the field of

broadband communication, it is nowadays possible to use network connections nearly everywhere thus allowing a user to be online all the times. Additionally, while the computational power and the storing capabilities increase, the size of today's mobile devices decreases. According to Bosomworth (2013), the market for mobile devices is growing more and more and in 3 years it should take over desktop internet usage. This mobile revolution is changing everyday life and offers new ways of learning. This also enables educational institutions and teachers to harness mobile learning solutions to offer more effective and richer learning experiences.

Mobile learning has some attributes that depend on the user: the user's environment and the used technology or device. It is a very time-constrained task delivering context-oriented content. Learning is normally done on-the-fly, which means that it is very fast and occurs mostly during spare time. Thus, the information provided has to be personalized to the needs of the user. Combining contextual and mobile learning, we can use context information to choose the most appropriate information or learning material. Furthermore, mobile learning includes multimodal interaction using several technologies handled on the mobile device, like speech recognition, sound, touch gestures, etc. (Pisey et al. 2012; Kaliisa and Picard 2017). Lastly, mobile learning can also support collaboration, where the user contacts their fellow students, friends, or experts (Pedro et al. 2018).

Being mobile adds a new dimension to the activities that can be supported, both because of the personal and portable nature of the devices themselves and because of the kinds of interactions they can support with other learners and the environment. Klopfer et al. (2002) identify five properties of mobile devices that produce unique educational affordances in terms of portability, social interactivity, context sensitivity, connectivity, and individuality.

Mobile learning provides a potential way forward for the expansion of education programs to larger segments of the population rather than via the traditional eLearning model that has been adopted in much of the developed world. Valk et al. (2010) states that mobile learning allows a

method of educational delivery that could be more cost-effective than e-learning methods, not to mention that the ubiquity of mobile phones means that many people are already familiar with mobile phone applications.

However, if learning is to have a deep impact in the learning process, there are still several issues that should be properly addressed and considered. The former is the need of supporting temporal mobility. Dispersion in time makes it hard to define precisely the start and end of a mobile learning session. Learning scenarios should consider this aspect and support not only the spatial mobility of students but also their temporal mobility (for example, by giving the opportunity to easily stop and resume a session) (George and Lekira 2009). The latter is the importance to integrate mobile applications into global learning systems. The idea here is to let the learner easily switch between a desktop application and a mobile application. For that the user interface should be adaptive and the information gathered during mobile use should be reused on desktop applications in order to adapt the learning game to each learner experience (Cochrane 2010; Paredes and Ayala 2012).

Ubiquitous Learning

Ubiquitous learning (u-learning) in contrast to mobile learning is not necessarily bound to mobile devices. In general, u-learning is enabled by an environment that can be accessed in various contexts and situations. As Van't Hooft et al. (2007) states, u-learning involves learning in an environment where “all students have access to a variety of digital devices and services, including computers connected to the Internet and mobile computing devices, whenever and wherever they need them.”

Students in u-learning environments have the potential to increase their learning experiences because they can critically weight their peers' ideas, react more intentionally, and check the accuracy of their opinions or assertions (Chin et al. 2018). Students benefit by using the opportunity to engage more thoughtfully than they often do when called on to respond on demand in a classroom or on an in-class exam. Similarly,

teachers have more flexibility in the way they interact, with the capacity to tailor subsequent lessons and responses to meet students where they are, individually and collectively (Yang 2006). According to Pimmer et al. (2016), positive outcomes of ubiquitous learning appear mainly with instructionist and hybrid designs.

Yahya et al. (2010) advocate that u-learning should have the following characteristics:

- Permanency – the information remains unless the learners purposely remove it.
- Accessibility – the information is always available whenever the learners need to use it.
- Immediacy – the information can be retrieved immediately by the learners.
- Interactivity – the learners can interact with peers, teachers, and experts efficiently and effectively, through different media.
- Context-awareness – the environment can adapt to the learners real situation to provide adequate information for the learners.

Ubiquitous learning can be about the adoption of appropriate technologies for use in traditional education environments such as classrooms, or it may be about the alignment of ubiquitous platforms with more ubiquitous contexts of learning outside the formal classrooms, like in workplace, in the home, or in public places.

Educational-Game Design Process

Learning can become more effective if it becomes contextual, mobile, and ubiquitous. Cordova and Lepper (1996) demonstrated this concept by using some educational tasks, where learning embedded in a motivating setting improved learning outcomes and that engagement can facilitate learning. More recently, George and Serna (2011) structured the classification of activities around the main theories and areas of learning relevant to contextual mobile scenarios:

- Behaviorist – activities that promote learning as a change in observable actions.
- Constructivist – activities in which learners actively construct new ideas or concepts based on both their previous and current knowledge.

- Situated – activities that promote learning within an authentic context and culture.
- Collaborative – activities that promote learning through social interaction.
- Informal and lifelong – activities that support learning outside a dedicated learning environment and formal curriculum.
- Learning and teaching support – activities that assist in the coordination of learners and resources for learning activities.

George and Serna (2011) established that for the creation of a successful game-based learning opportunity, the following steps of game design, elements of learning, and engagement should be taken into consideration:

- Determine pedagogical approach – when designing an educational game, we have to reflect upon didactical approach and related topics.
- Situate the task in a model world – students should be able to discover meaningful relationships between abstract ideas and practical applications in the context of the real world; concepts are internalized through the process of discovering, reinforcing, and relating.
- Elaborate the details – educators should choose and design learning environments that incorporate as many different forms of experience as possible (social, cultural, physical, and psychological) in working toward the desired learning outcomes.
- Map learning activities and concepts to interface actions and objects – the idea is to create polished products and activities valuable in their own right, enabling the learning process to occur in a real world scenario.

There are many interactive learning techniques that have already been used in game-based learning. According to Prensky (2013), one of those techniques is “learning from mistakes,” where failure is considered a point where the user gets some feedback. In game-based learning, making a mistake is a primary way to learn and is considered the motivation for players to keep on trying. Additionally, students should also be able to

assess their own activities to see how they are doing and to be able to evaluate their decisions and actions. There must be a close link between action and feedback, which will motivate students to keep playing the game (Westera 2019).

The Walkabout Initiative

Design-based research was the main method applied in this project. Based on the teaching, coaching, and managing experiences of the participating lecturers, a rough working method was set up in which different teams of students needed to collaborate. As a part of the working method, students were free to team up. Only one specification was given, each member must come from a different country. Initially, eight groups of five (or four) students were formed and were assigned a mentor. The resulting teams were quite different in formation. One team had only male students, and another team was mono-disciplinary. All teams were then formally informed on the task at hand to build a mobile contextual learning game given the context of the park with its themes and animals. From that point forwards an iterative process of mentoring and giving feedback started. Each morning all mentors briefed each other on the current developments and the overall impression on the progress of the project. During the day, all teams were briefed and coached by their mentors.

Within the whole group of students, two subgroups were identified. The Tech group was responsible for the technical development of the game. On the other side, the Art group was responsible for the learning and multimedia contents. Both groups were regularly called to meet as a group with the Tech mentor and the Art mentor. During those meetings training, feedback and specific instructions were given. The training sessions addressed issues as understanding the gaming system, taking leadership, teambuilding, and project management. The members of the Art group were instructed to take leadership over their team, and these team leaders were informed on the long-term and the short-term schedules.

WalkAbout IP ran for 10 working days, which is a short time to produce a full scale contextual

learning mobile game. Therefore two schedules, one short term and one long term, were defined. The long-term planning spanned the 10 days of the project and specified two sprints of 4 days. The short-term planning was a day-to-day planning for the game development, game presentation, and the feedback on the teams' progress. At the end of the first sprint, a game demo was presented; after the second sprint, the teams needed to demonstrate indoors a playable game using a mobile device (tablet or smartphone). During the last day of the IP, all teams evaluated the working games in the field. Due to the design-based approach, the team of lecturers was able to correct and steer the flow of the project.

As the project provided a real educational context, its results can effectively be used to improve practice in at least a likewise context. The iterative interventions, using mixed methods as training and assessments during the project, were constantly evaluated for their effectiveness. The evaluation was done by continuously checking the impact of the interventions on the teams' progress and the feedback coming back from the students.

The event took place at the Biological Park of Gaia, which is a small nature reserve center on environmental education. It has a natural

discovery course of about 3 km where the visitors can see more than 200 species of animals mainly of the Iberian fauna, either in captivity or in freedom.

The Park plays one of the most important functions of the green zones, the contact with nature source of psychological balance. This function is enhanced by the Park's apparent spatial disorganization resulting from the refusal of the formal garden or park model. Biological Park tries to preserve the typical landscape of the region, while it was essentially a large agricultural area.

A key objective of the Park is to point out the need to plan the territory, to maintain large green spaces in the cities, and to protect rivers, fauna, flora, traditional construction, a set of referential values of our civilization. Environmental education is a process of captivating and involving the citizen in solving the environmental problems that afflict humanity; a good way to begin this process is by demonstrating the contradictions of the great city and what it means for each of us in terms of quality of life.

Teams may place contextual serious games in each of the 18 points of the Park (Fig. 1), which includes: (1) host center, (2) picnic area, (3) exposure "from the rainforest to the desert,"

WalkAbout Framework for Contextual Learning Through Mobile Serious Games, Fig. 1 Map of Biological Park of Gaia

(4) estuarine birds, (5) badgers and otters, (6) kites, (7) Santo Tusso's farm, (8) exhibition "mills and implements," (9) foxes, (10) wild goats and wild boars, (11) bucks, (12) Bogas's farm, (13) European bison, (14) Chaso's farm, (15) day-time prey, (16) lake, (17) waterfowl, and (18) Cunha's farm.

Evaluating the WalkAbout Initiative

Part of the project was intended to analyze the perception of learning while performing a specific task in a specific setting. The setting was an international interdisciplinary team, and the task was to build a contextual learning game. During the IP, the students were asked to fill out two questionnaires. Two sets of questions were proposed to a group of (Finnish) students during a quantitative research methods course, and they derived the final sets of questions which were implemented in the questionnaires.

A total of 31 students from our initial group of 40 filled the questionnaires. Six students of 31 responses answered they had already worked in an international interdisciplinary team. These students all indicated that such a team is a powerful working environment although communication and language barriers are the main problem in such a team. Four of these students mentioned they had learned a lot through synergy.

Of those students (25 of 31) who had never worked in an international interdisciplinary team, 22 think working in such a team is very useful, although, they all expect communication and language to be a problem. Almost all (20) are anticipating learning to collaborate with other people, having a different education, different culture, and different opinions.

Except for one student, none had ever built a mobile contextual game. Twenty-seven students (of 30 responses) have the opinion that one can learn a lot through building a contextual mobile game. What students think they will learn is very different. Most expectations lie in the line of the student's current program. An IT student expects to learn more on JavaScript and mobile technologies, a student from teacher training expects to

WalkAbout Framework for Contextual Learning Through Mobile Serious Games, Table 1 Topics expected to learn by students

31 responses in total	Absolute frequency	Relative frequency (%)
Language	14	15
Social	9	10
Communication	17	18
Team work	21	23
Technical	17	18
Management	6	7
Creativity	7	8
Presentation skills	1	1
Other	0	0

learn how to deliver learning content in a more appealing manner, and, finally, most students expect to learn to collaborate with people. Only a few students (2 of 30) expects to learn something on games/puzzles/challenges and how they are built, one student thinks he will learn something from the context, and five students mention teamwork, time management, and organization.

When offered a choice of what they expect to learn during the IP, they answered as follows in Table 1. Each student was asked to choose maximum three topics. A likewise question about the topics learnt by students (Table 2) was asked in the second questionnaire. In two questions, students were asked how they experienced relations between teams in terms of competition and collaboration. To the question "How did relations between teams influenced your team [Competition]?" 1 student answered "A little bit in a bad way," 17 answered "A little bit in a good way," and 12 said "Strongly in a good way." In relation to the question "How did relations between teams influenced your team [Collaboration (did your team receive help from other teams)]?" 3 students answered "A little bit in a bad way," 13 students answered "A little bit in a good way," and 12 students said "Strongly in a good way."

In an open question on the quality of the teams, some students complained that their team with fewer disciplines (7 IT students and 1 non-IT) was considerably weaker in comparison to teams with a richer spread of disciplines (IT, tourism, and teacher training).

WalkAbout Framework for Contextual Learning Through Mobile Serious Games, Table 2 Topics learnt by students

What did you learn? 30 responses in total	Nothing	Superficial (a little)	In depth (a lot)
Language	0	15 (50%)	15 (50%)
Social	0	7 (23%)	23 (77%)
Communication	0	5 (17%)	25 (83%)
Team work	1 (3%)	3 (10%)	26 (87%)
Technical	5 (17%)	12 (40%)	13 (43%)
Management	1 (3%)	13 (43%)	16 (53%)
Creativity	1 (3%)	7 (23%)	22 (73%)
Presentation skills	0	6 (20%)	24 (80%)
Game design	4 (13%)	12 (40%)	14 (47%)
Instructional design	5 (17%)	13 (43%)	12 (40%)
Programming/ coding	8 (27%)	13 (43%)	9 (30%)
Graphics	8 (27%)	14 (47%)	8 (27%)
Animals (context)	3 (10%)	11 (37%)	16 (53%)
Environmental conservation (context)	5 (17%)	12 (40%)	13 (43%)
Evolution theory (context)	10 (33%)	8 (27%)	12 (40%)

Although the heavy workload, all students were explicitly enthusiastic about their participation and the overall outcome of the IP, wondering what could have been realized in more time considering what they had produced in the present small time frame.

We also inquired students about the usefulness of the daily break up meetings and session with mentors. The feedback given by students is shown in Table 3.

Another interesting point to analyze is the internal evaluation made by teams regarding the capabilities demonstrated by each student along the project. The overall results of this evaluation about criteria such as initiative, responsibility, time scheduling, attitude towards working, and cooperation is shown in Table 4. The last column indicates the average final score given by external experts during the presentation of the projects by the teams.

WalkAbout Framework for Contextual Learning Through Mobile Serious Games, Table 3 Perception about the usefulness of feedback sessions

Ranking	How useful were the feedback sessions? [Art/Tech break up]	How useful were the feedback sessions? [Sessions with mentors]
Bad	1 (3%)	0
No use	2 (7%)	0
Good	16 (53%)	7 (23%)
Very good	8 (27%)	13 (43%)
Excellent	3 (10%)	10 (33%)

When we analyze the impact of each criterion in the overall performance of each team, we obtained the following results depicted in Table 5. The results of Table 5 show that cooperation is the main attribute demonstrated by the teams. On the opposite side, deliver work in time scheduling and initiative were the main issues faced by the teams. There is a clear dependence between the initiative and cooperation demonstrated by the teams in terms of the final results obtained by them. On the opposite side, the responsibility does not show to have a deep impact in the overall quality of work developed by the teams.

Exploring the Impact of WalkAbout Initiative

The primary aim of this project was to get students to form international teams and work together on a project. To this end, the project was a big success. From the outset the students engaged in the process. Prior to travel, a Facebook page was set up in the hope that the students would start communicating with each other. The Facebook page, introducing WalkAbout IP, was accompanied by two private groups, one for the participating teachers and one for the participating students. All students were invited to become a member of the student group in order to get to know each other and to start forming teams. The Facebook page was initially used to inform all involved about the proceedings of the preparations of the IP. During and after the IP, participants used the page to publish

WalkAbout Framework for Contextual Learning Through Mobile Serious Games, Table 4 Perception of students capabilities distributed by each group

	Initiative	Responsibility	Time scheduling	Attitude towards working	Cooperation	Final score (external experts)
Animal Quest	4,06	3,88	4,06	3,94	4,31	3,61
Project Bird	3,94	3,81	3,88	3,75	4,25	2,78

team statuses, social activities, and pictures. Students also expressed their frustrations and achievements on the page. On the first day of the project, the students arrived at the accommodation, from their various countries, at various times. They knew that the following day they were going to be assigned a team in which there would be at most one person from each country. They were informed that they could form their own teams if they wished and the lecturers would create the teams should this not happen. We were pleased to hear that they had all met up with each other during that first evening, mingled well, and had happily assigned themselves to teams before the end of the night. It was felt that allowing them to form their own teams was an important part of them buying into the process. Based on observational data was noted that the students tended to hang around with their team members and not their fellow countrymen. Unfortunately, the home country did not quite have the same

experience. They were not living in the same accommodation as the others, and furthermore, their college was still running (evening) classes as normal. This meant that, in general, there was not the same level of participation from those students. This situation helps to understand the low score of criteria initiative and time scheduling (Table 5).

A secondary aim was to see if we could get the students to produce a prototype mobile game that would have commercial appeal. Again, the project was a success on this front. While each of the seven teams was given the same context, information and set-up they produced very different but thought-provoking concepts mostly aimed at a younger audience. The variety of concepts included using logic puzzles, puzzles involving sound, moral issues, creating personal databases and education. The commercial aspect was evidenced as the National Park requested that two of the games

be worked on further with a view to making them a permanent feature.

A tertiary aim was to test the capabilities of the chosen framework, WalkAbout. Given that the entire project had to take place during 2 weeks, we required a framework that could rapidly turn concepts into games. This framework was designed to use QR codes that, in essence, indexed a database that could be used in both an online and offline setting. WalkAbout is designed to be a platform-independent application so a student only need know about HTML5, CSS, and JavaScript, i.e., no native coding was necessary. The online/offline aspect meant that a person could download a game when they had an internet connection but could then play the game offline. Once an internet connection was reestablished, other features such as leaderboards could be displayed. This was a highly desirable feature as it allowed games to be played in areas where there was no internet coverage or indeed where it was expensive. Thus, a typical game developed by the students involved scanning a QR code and being asked to solve a puzzle, which in turn led the student to another QR code.

While the framework had its limitations, some of these helped the teams focus their attention and home in on a concept quickly. It is worth noting that the students came from a wide variety of backgrounds including tourism, teacher training, applied informatics, games development, and telecommunications, and there was a wide variety in programming skills. That said, each team needed at least one good programmer, as there were many technical issues that needed to be solved during the duration of the project, and unfortunately, the documentation was poor. This was offset by having the framework's creator available during the first week of the project. The need for a good programmer meant that there was a big variety in successfully implementing games. While some managed to produce a fully working prototype, others had to abandon the framework altogether and concentrate on the concept. While WalkAbout performed admirably, we have learned that we need to be careful in our selection of students so that we get a reasonable balance of technically skilled as well

as creative thinkers. Furthermore, it was felt that it would be a good idea to introduce the framework to the technical students in advance. This initiative would help students to increase their learning competences in technical skills, which is one of poorest criterion scored in Table 2.

With regards the methodology, it was felt that we managed to bring out the best in the students. They fully engaged with the project and the words "Intensive Programme" was truly fitting. The feedback sessions were considered very useful by our students (Table 3) and let them to share their thoughts and issues regarding the game design and implementation processes. While the output of the students was undeniably excellent, there were concerns that maybe it was too intensive. There was not much time set aside for relaxation. Also, there were many instances of students staying up all night working, and while they did this out of love of their project, one has to question whether this is a desirable feature of future projects. We should also keep in mind that, for most students, this is taking place near the end of an academic semester, and when they return to their own college, they must reengage in their normal studies.

In looking to the future, we need to review the balance between the desirable aspects, the limitations, and the goals of this project which include:

- The feeling one gets from producing a high quality and commercially viable product.
- The experience of working intensively, within a diverse team, and acquiring the knowledge that this is usually required if a quality product is going to be produced.
- The experience has to take place in under 2 weeks.
- The primary goal is to get students working in international teams.
- The acceptance that some students are nearing the end of their studies and we should not send them home completely exhausted.

While our existing process does a good job of balancing these, it is felt that final point needs to be improved. Although efforts were made to allow thorough communication and information

towards the students' months before the start of the IP, a lot of the information was not received by students. Optimizing communication will allow us to prepare ourselves and the students more and better for the upcoming IP.

Conclusion

The WalkAbout Framework has been explored by teachers, students, and researchers from different nationalities and multidisciplinary domains to create contextual learning environments through the use of mobile serious games. This framework was designed and tested in the context of the Biological Park of Gaia for 2 weeks within a European exchange program. Throughout this period, students from different countries with very different competences, such as IT, education, and social sciences, have created contextual and mobile games involving several technologies, such as mobile networking, mobile programming, object-oriented databases, QR tags, and near-field communication (NFC). These games were previously tested by employees and park visitors.

The creation of immersive learning environments can only be achieved by identifying relevant contextual information. The Biological Park of Gaia was an ideal setting for the students involved in each project to let them realize the importance of perceiving the context in which the game is played, which allowed them to develop new knowledge in botany, biology, and zoology fields.

Interaction among students is a crucial aspect in the development of contextual serious games. The challenge was very demanding as it involved students from various countries. In this sense, teams were built involving students from several countries and with multidisciplinary and complementary competences that guarantee a good balance between technically and creative skilled. Additionally, new friendship relationships were created even after completion of the IP program. This situation was also important in motivating students to carry out an Erasmus+ exchange program throughout their courses.

Offering an immersive experience to the player was another goal of this project. In this sense, each developed game has very different approaches, from adventure games, logic games, action games, multilevel games, among others, which allow players to feel constantly challenged. The possibility to share the players' performance in social networks is also another feature that enhances the disclosure of the games and also raises a greater competitiveness among players.

Finally, it is important that this experience effectively helps students in acquiring new skills. Students from social sciences had the opportunity to collaborate with other students with different competences. This will allow them to better understand the challenges they will encounter in the job market. For their part, students in the IT area have developed new social and technical skills. Although in the context of the course already have knowledge with technologies such as HTML5, JavaScript, and CSS, they did not have yet the opportunity to develop a real project that involved all these technologies. Additionally, they developed new technical competencies in JSON, NFC, and object-oriented databases.

[Online communication](#); [Social media](#); [Social networking](#); [WhatsApp](#); [Online messaging platform](#)

Definition

WhatsApp is a free, cross-platform messaging and Voice over IP service owned by Facebook. It allows the sending of text messages and voice calls, as well as video calls, images and other media, documents, and user location.

Alongside social media, mobile instant messaging services such as WhatsApp and Facebook messenger have rapidly transformed the way people communicate. Much like social media, instant messaging platforms are used to connect, collaborate, socialize, and coordinate. They can be used to share images, videos, documents, and audio files, to make calls, and to send texts to individuals or groups of up to 200 people at once. The point of difference from social media is that messages sent via instant messaging services can only be sent to those who are in your contact list; they are not public feeds as per social media.

This entry focuses on how one such instant messaging service – WhatsApp – is used to support learning in higher education. WhatsApp has emerged as one of the most popular instant messaging services for smartphones. It is used by more than one billion people in over 180 countries and is the most popular mobile instant messaging app used in the Middle East region. WhatsApp is used widely across many fields including in the dissemination of political campaign messages, by health professionals to share information about patients, and by the media as a forum to keep updated on the experiences and interests of their readership.

The potential of using WhatsApp to enhance learning is gaining momentum. While research is still in its infancy, the emerging body of literature points to the positive ways this app can be used to provide student feedback and to enhance reflection and learning. Key to these benefits is its easy accessibility, and its low cost (it does not incur any SMS or additional charges to use). This makes it ideal for millennial students who are already high users of online communication tools, plus also for educational use where budgetary constraints can impact on opportunities for educators and students to trial and implement new ways of using technology.

Effective Feedback

A key idea informing the discussion presented in this entry is that feedback is one of the most powerful influences on learning and achievement; this impact however can be either positive or negative. The type of feedback and the way it is given can influence learning differently. Superficial feedback or feedback for feedback's sake has no measurable benefit to learning outcomes. In addition, feedback that is highly critical can cause students to disengage. In their analysis of more than 7000 studies on the implications of feedback on learning and achievement, Hattie and Timperley (2007) conclude that effective feedback is that which is timely (immediate and not delayed); instructional (aims to deepen understanding of the content, is specific, prompts deeper enquiry and self-adjustments); and supportive (relevant and encouraging, helps them to understand themselves as a learner.)

This entry presents some of the most recent research that has been undertaken of the use of WhatsApp in higher education in relation to student feedback, reflection, and learning. Much of this research has been undertaken in developing countries such as Africa and the Middle East where use of WhatsApp is very popular. This entry focuses on why this application is being used in the ways it is and the educational value that is emerging for tertiary learners. The aim is to support practitioners, academics, and graduate students in their understanding of this new direction in educational technology, so as to make informed decisions on its usefulness and applicability to their current practice and research.

Key Reason for Use of WhatsApp

The rise in use of WhatsApp in education has been organic (as opposed to a planned strategy) and stems from its ease of use and its familiarity to educators and students who already make extensive use of this application in their personal life. For example, of the 200 university students participating in Appiah's (2016) study, 46% used WhatsApp 10 or more times per day; 26% used

it 7–9 times a day; and 13%, use it 1–3 times a day. Other studies have found similar results (Jain et al. 2016). Similarly, Appiah et al. (2016) found that of the 180 university educators participating in their study, 46% use WhatsApp more than 10 times daily, 26% use it 7 times daily, 14% others use it maximum of 3 times daily, and 12% used it 4–6 times every day.

Familiarity with an online application eases the physical and mental effort needed to use it, and this positively influences attitudes and openness as an e-learning platform. Building on their familiarity, educators and students have begun using WhatsApp as an alternative to using university email or online learning management systems (LMS) for online communication, collaboration, and access to learning materials. LMSs are routinely made available in higher education for educators to make announcements, to share ideas and resources, and to implement online discussions with students. Research (Wilcox et al. 2016) however shows disconnect between design and usability. LMS are most effectively used on laptops; however students often use smartphones to access a LMS. As a result, the interface, navigation, and features of the LMS for smartphone use is very limited; often it cannot even be viewed on smartphones. Notifications are not received if your question has been answered or if new files have been uploaded, and multiple log-ins may also be required with each follow-up visit to a LMS. This creates a tedious usability issue for the students and instructors (Wilcox et al. 2016) and effects the ability and inclination of students to use this platform to access content, connect with their educator, and connect with peers.

WhatsApp provides the same built-in functions to an LMS yet offers considerable enhanced ease in accessing them. It can be easily retrieved via a smartphone and does not require multiple log-ins with each use. This combination is much more conducive to educators and students continuing their communication beyond the classroom and can supplement or replace technologies beyond those provided by the university to support their social interactions and participation in their learning.

How WhatsApp Is Used and Benefits

Research (Raiman et al. 2017; Doolan and Gilbert 2017) shows that students and educators use WhatsApp as a back-channel for connecting with each other and accessing learning materials outside the classroom, student-to-student, and/or student-educator. A key benefit of value to students and to educators is that the informal shared discussions contribute to fostering an inclusive learning community that builds confidence, reflection, and responsive feedback. On the other hand, educators can experience the expectation that they are available 24/7 to be an imposition on their time and personal life and exacerbating an already demanding teaching role. The following section provides an overview of the key advantages and disadvantages identified in recent literature for using WhatsApp in higher education.

Student to Student

Research shows that students use WhatsApp to help other students by sharing content, experiences, and/or insights with each other. They regularly use WhatsApp for sharing materials such as images and sketches of work undertaken (Appiah 2016; Raiman et al. 2017). Students find value in using WhatsApp for real-time discussions occurring at key learning times such as when putting together their evidence for the final assessment (Jain et al. 2016; Doolan and Gilbert 2017). In comparisons to a LMS, students participating in Doolan and Gilbert's study (Doolan and Gilbert 2017) valued the app as, "a far quicker and more responsive way of communication"; it enables "increased productivity and friendships as everyone could speak with everyone in the group," and it's "simplicity and because we all use it already." The specific and targeted advice occurring in WhatsApp group chats between students importantly facilitate relevant and encouraging advice and feedback that prompts deeper inquiry and self-adjustment (Hattie and Timperley 2007).

Students experienced WhatsApp participation created a more inclusive learning group that contributed to breaking down barriers commonly experienced in the classroom. For example, students in Jain et al. (2016) study considered the

sharing of ideas informally online, strengthened the bond between them, and helped develop their confidence as learners. This study showed that students felt encouraged by their peers to share and articulate further ideas. WhatsApp chats circumvent the time restraints of classrooms that may limit opportunities for students to speak and what some students consider to be an uncomfortable or confrontational environment for "taking the floor" and openly reflecting on the content.

Similarly, other research found WhatsApp participation alleviated difficulties caused by over-talkative students taking over classroom discussion, use of WhatsApp allowed others to be heard (Doolan and Gilbert 2017). Ongoing opportunities to articulate, clarify, and reflect on the curriculum content with their peers and to receive feedback increased their control and independence as learners (Bere and Rambe 2016) and enhanced the academic performance of students (Doolan and Gilbert 2017). Explanation by one student from Naidoo and Kopung's (2016) study is representative of this thinking, "...the WhatsApp instant messaging made me realize the worth of my classmates. Contributions they made significantly contributed to my knowledge of mathematics. I learnt a lot of mathematical concepts and problem-solving strategies from my classmates..."

Educator to Student

The value of the frequent student-educator communication that takes place using WhatsApp is another important benefit emerging in the research. The use of WhatsApp facilitates forming learning communities of students and educators engaging in academic dialogue, with a focus on information sharing, clarification, and further application of knowledge (Jain et al. 2016; Raiman et al. 2017). Of significance is that the communication via WhatsApp is sought out and initiated by students and by educators, suggesting its usefulness for both stakeholder groups. Approximately 50% of students use WhatsApp for teacher availability (Appiah 2016). Similarly, it is used by educators to build a sense of community to develop a deeper acquaintance with students 60%, sense of

belonging to the group 38%, and quality of expression among student 46% (Appiah et al. 2016).

The app is used in student-educator communication to ask and reply to questions and concerns, to contribute to group chats (with all students enrolled in the subjects as well as in subgroups of students), and to upload resources to each other (Appiah 2016). Through group chats, students also have the opportunity to witness faculty interacting with other students and learn from such interactions. Students also valued the opportunity to read and re-read feedback by educators “I can always refer back to the previous messages so that I won’t forgot the old information when I do revisions” (Jain et al. 2016).

The faculty member’s availability and helpfulness and quality and frequency of feedback had a significant impact on student experience (Jain et al. 2016). Targeted talk and focused explanation that addressed the queries of individual needs, corrected or reinforced knowledge, and promoted reflection by both educator and students had a positive effect on students’ sense of connection to the subject and to the educator (Jain et al. 2016). Group chat also facilitates the opportunity for educators to communicate sporadic learning opportunities to students for students to apply their learning, for example, its use by tutors with medical students, “There’s an ABPI that needs doing on [Ward name] if you want to join” (Raiman et al. 2017). Students also reported being more engaged when in class as a result of instant messaging: “Messaging made the session far more stimulating. We were able to focus on specific problems we had in the session. This made the whole learning experience far more useful and specific to us” (Raiman et al. 2017).

The research indicates that the use of WhatsApp by educators and students is conducive to providing quality feedback that is immediate, targeted, relevant and encouraging, and constructive. This is facilitated by the real-time and any-time discussion students could participate in with their peers and educators. Such feedback provided students the opportunity and encouragement to correct mistakes immediately and prompted deeper enquiry and self-adjustment (Hattie and Timperley 2007).

Challenges

While the advantages of using WhatsApp instant messaging have been discussed above, WhatsApp instant messaging can pose educational challenges. Given that a single-text message is restrained to 139 characters, the short message length and succinctness of language required can pose limitations. The limited keyboard can also hinder questions or discussion of particular curriculum content, for example, using content such as mathematical symbols which are not part of the allocated keyboard (Naidoo and Kopung 2016). This can lead to limitations when ask or respond to question or completely avoiding some questions because it would be difficult to write them on WhatsApp instant messaging.

While some research indicates that students and educators view group messages as positive, and comparable to the social messages they receive from their other WhatsApp contacts (Raimen et al. 2017), intrusion on personal time and unwanted extracurricular work can contribute to reluctance to use WhatsApp for educational purposes (Susilo 2014). Message flooding, highly time-consuming, group maintenance, expectation for high availability of teachers, students’ usage of inappropriate language, and overexposure to students’ personal life are challenges to educators’ commitment to using it to promote feedback and reflection (Appiah 2016). Good feedback is that which is well-timed and does not distract from learning (Hattie and Timperley 2007). While this is often considered from the students’ perspective, it is also important to consider “timing” from the perspective of the educator. The use of WhatsApp group chat can exacerbate the time required of educators to fulfill an already demanding role. This may result in less availability or reduced feedback to manage this aspect of feedback.

Conclusion

This entry sheds light on the various benefits of using WhatsApp Group as a platform for

academic discussion to take place. Three features – easy accessibility, minimal cost, and multi-modality features – are important to the effectiveness of its use to provide feedback, support reflection, and promote learning. As the literature indicates, when used well, it creates an organic and iterative learning environment for students. Educators and students become important stakeholders in the process and provide valuable feedback that can be used to refine and improve performance outcomes for everyone (Hattie and Timperley 2007). Several challenges of using WhatsApp include interference with private lives, additional work for educators and improper language use by students. These are important considerations and if not managed well can hinder the benefits of using WhatsApp to promote student learning.

It is hoped that this outline will promote further research among other researchers interested in examining the use of WhatsApp or other instant messaging platforms for teaching and learning purposes. It is also hoped that this entry promotes reflection for practicing teachers and student teachers on the usefulness of WhatsApp for their educational environment. Not all feedback is equal, and not all students and classroom environments are equal. Consideration can be given to the advantages and disadvantages of local use of this app for student learning in the short-term and long-term.

Why Teach History of Computing?

John Impagliazzo

School of Engineering and Applied Science,
Hofstra University, Hempstead, NY, USA

Synonyms

Computing history; Computing education; History in computing education

Overview

This entry, an integration of material from earlier works (Impagliazzo 2005; Impagliazzo and Samaka 2013), provides a rationale for incorporating history in computing student experiences. It also shows ways in which computing history can make the delivery of teaching computing courses relevant. The approach suggests the use of computing history as a recurring theme throughout courses through relevant historical stories or material to enhance course delivery and to capture student interest. The use of computing history often makes positive and constructive improvements in student experiences by making topics more interesting and stimulating. It informs students of nontechnical elements within their computing specialties.

Computing history could be an effective pedagogical tool to teach computing courses (Impagliazzo et al. 1999). History contributes to students' lifelong learning experiences, and it also enables students to gain a better sense of the nature of inquiry, the processes of innovation, and the human dimension. Ideally, it would be good if all computing students had a requirement to take a specialized course on the history of computing. Because of curricular limitations, this option is likely unattainable. Hence, embedding history within courses is more feasible and can become an effective pedagogical tool to teach computing courses.

History enables students to explore computing beyond hardware and software, and it expands

students' views on ways in which computing affects society. For example, diversions could include simple stories used to enhance student learning. Teachers can use computing history as a thread throughout student experiences to foster constructive transformations from sterile factual content to dynamic interludes involving people, places, and events. Teachers could also use computing history as a vehicle for extra credit or topic enrichment, particularly for students who enjoy the softer side of the computing field.

Role of Storytelling

Presenting any history as a series of chronological facts is often uninteresting and could be counterproductive. Alternatively, storytelling within the context of student experiences can enrich a subject while connecting students with human elements and can make computing courses more interesting. Moreover, the computing information and knowledge embedded within these stories are often relevant to some aspect of students' own lives. Hence, they often remember the stories and the computing content within them.

Teachers should adopt more innovative and interesting approaches toward student learning to achieve student success. Computer scientist Christos Papadimitriou stated:

This narrative mode (storytelling) of thought is fundamental for at least two reasons: First, narrative richness is an essential precondition for the self (the converse is, of course, trivial: there can be no narration without narrator). We think of ourselves almost exclusively in terms of our mental autobiography. Second, stories are in a certain intrinsic sense interesting, in that they are attractive, high-priority memory fodder. Everything else being equal, we are much more likely to remember a story than a logical argument. (Papadimitriou 2003)

This statement is very true. Students, especially those not specializing in computing, are more likely to remember a story about computing than a fact concerning it.

While storytelling could be quite effective, teachers should not expect that using this technique is always easy. Stories should evolve naturally and they must relate to the topic under discussion.

Sources for such stories could emerge from current happenings or events such as a newspaper article, or they might build on some historical background such as a book on computing history. Whatever the source, teachers should try to research historical topics, so the stories they tell are meaningful to the topic. Storytelling associates students with different perspectives toward computing, and it connects them with people, places, and events. Therefore, active involvement by teachers coupled with active participation by students can make historical storytelling a memorable component to all computing courses.

Relevance and Computing History

Teachers can use history as a vehicle to enrich specialized course studies and to derive other benefits from learning. One reason is the necessity of understanding and critical thinking. Another is the adage of heeding the past to avoid repeating the future. Indeed, the statement by George Santayana that states “Those who cannot remember the past are condemned to repeat it” (Santayana 1905) already exists within the fabric of the computing field. There are many stories on repeating the mistakes of prior happenings; many are well known. For example, how can we explain the cause for the downfall and ultimate demise of Control Data Corporation (CDC)? What caused Digital Equipment Corporation (DEC) to fail? In the mid-2000s, IBM surrendered its personal computer business to Lenovo. Why did IBM do this when “Big Blue” was synonymous with computing machines? Answers to such questions are quite complex. Nevertheless, the questions do form a starting point for student interaction in a classroom setting and for stimulating new ideas and concepts. For some students, they may even provide a basis for more exploratory study and research.

Computing history also provides fodder for curiosity and intrigue. For example, as far back as 2001, Microsoft started developing its Surface computer, which became a reality as a coffee table in 2004 and formally unveiled in 2007 (CNN 2012). Yet, other companies have exploited that technology in the manufacturing

of tablets and smartphones in the latter part of that decade. Exploring reasons why a company develops a technology while competitors take advantage of it could be an effective way to engage students in a topic and promote frank or even heated class discussions.

Curiosity is another trait of history. Why did company X do this? Why didn’t industry Y do that? How did someone come up with an idea such as Z? It is important to dismiss the notion that the only concern of history is on events from the past. Answers to questions as just mentioned can make history futuristic. Building on the past successes of others is useful in a modern age; avoiding the mistakes of others is even more useful.

Computing professionals (practitioners and teachers) have often ignored the history of their field. They often favor innovative approaches while disregarding the past. Although some organizations have contributed to history preservation, the contributions are isolated and often incomplete. Specialized textbooks on technical subjects often do not contain elements on the history of the subject, and when they do, they often contain myths and inaccuracies. However, in recent times, a resurgence is developing where greater awareness of computing history is making strides. Websites such as the IT History Society and conferences such as those held by the Society for the History of Technology (SHOT) address the importance of the topic.

History Within Courses

The following briefly illustrates ways in which computing history can complement and enrich some of the computing courses found in a computing curriculum.

History and Computer Architecture

Computer architecture courses are one area where the history of the subject has received attention. Many textbooks in this area often contain sections, appendices, or sidebar vignettes that contain images that support the machines under discussion. Students often find such historical attention interesting and revealing.

Introducing students to computers without discussing their “invention” leaves a void in their education and a lost opportunity to question the inspiration of pioneers. For example, one might start a course with the question, “Who invented the computer?” and admonish those students who quickly utter “Bill Gates” or “Steve Jobs” in response. A homework activity can surface and names such as Babbage, Turing, Atanasoff, Zuse, and Mauchly emerge. A few students can “get hooked” into the intrigue, and before long, they develop an interest in computing history. The question of the invention of the computer is complex and is not within the scope of this narrative. Nevertheless, it does provide a good starting point to engage students in seeking answers to legal and ethical questions.

It is natural that computers become part of computing history since computing machines are tangible artifacts and have easy recognition by most people, even to nonspecialists in computing. Additionally, teachers wonder sometimes whether students have ever seen the internals of a computer and its electrical and electronic elements such as resistors, capacitors, flash memory chips, busses, or motherboards. More importantly, do these computing specialists know the way these elements work? Notwithstanding, an overview of the history of the subject would naturally expose such elements at least through images if not through visits to computing museums such as the Computer History Museum in California, the Science Museum in London, or the Deutsches Museum in Munich.

History and Computer Networks

Communication networks is another area where computing history received attention. The Internet as we know it has propelled much of this attention. Making this topic relevant in a modern communications course adds meaning and interesting knowledge. We could trace the root of the Internet to 1957 when the former Soviet Union successfully launched Sputnik. Students might ask, what does Sputnik have to do with the Internet? In response to Sputnik’s launch, the United States formed the Advanced Research Projects Agency (ARPA) in 1958 within its

Department of Defense (DoD). The purpose of ARPA was to establish a military advantage in science and technology, since a satellite launch from a seemingly adverse country posed a national security threat.

Students find stories such as this one rather fascinating. They provide fodder for further exploration on topics such as:

- How many nodes were on the original Internet?
- How many nodes are on the Internet today?
- How does one count such nodes and who does the counting?
- How does the Internet contrast with the World Wide Web?
- Are the Internet and the World Wide Web the same thing?
- If not, how do they differ?
- Can one exist without the other?

These and other related questions lead to formal and interpersonal discussions that open new areas of knowledge. This approach adds relevancy and enrichment to a topic or subject and makes network or communications classes more inviting.

History and Introductory Courses

In any curriculum, introductory courses often serve as the key to stimulate and maintain students’ interest and enthusiasm in the subject. They serve in some cases as an enrichment experience for the subject, and they might even serve as a general institutional requirement. Introductory courses also encourage students to develop some understanding of the subject’s concepts and fundamentals and, where appropriate, to develop skills that will serve them in future studies. Within an introductory computing course, the inclusion of historical elements has the advantage of making students think beyond the normal computing topics.

The use of history in a computing overview course is ideal. The broad scope of the overview course, often taken students from different specialties, shows students that the field of computing is more than a narrow orientation.

In fact, it is more about an exploration of computing where teachers can easily tailor history into its syllabus. The overview course presents many opportunities for students to explore extensions of topics on their own. Students tend to appreciate historical excursions, and they can relate their finding to relevant topics in their contemporary settings.

History and Other Specialized Courses

Teachers can use computing history in other computing subject areas as a vehicle to generate some excitement and interest. However, the “show-and-tell” strategy can become limited. With integrated networks and “system on a chip” (SOC) technologies in today’s world, it is difficult to demonstrate physical entities compared to demonstrations of valves or vacuum tubes, transistors, floppy disks, and the like that we could do with computers from the past. Yet, even though an entire computer system is in the shape of a small geometric entity or cube, it is possible to establish interesting stories such as the evolution of the ENIAC that occupied a large room to modern versions of SOC’s.

The strategy of show-and-tell becomes even more limited as we move away from tangible computing entities to intangible ones. What would one show physically about software other than a package or a download of a language product or an operating system? Yet their history remains rich. For example, students could trace the ancestry of a modern language such as C#. The same is true with operating systems. Teachers can pose interesting questions such as what is the status of COBOL and FORTRAN languages or why did the IBM OS2 operating system die.

Many charts and timelines exist on tracing the roots of computing languages and operating systems. We have marveled at the way students enjoy the fascination of seeing ways in which different languages emerged. Additionally, we see that students do appreciate exploring the relevancy of past languages to the languages in use today. With operating systems, student response to learning historical connections is similar. Students can develop a keen interest in the

study of the origins of programming languages and operating systems where teachers can direct them to communities of special interest such as SIGPLAN of ACM or to some specialized literature of books. The proceedings of two conferences, namely, the “History of Programming Languages” (HOPL) in 1978 (Wexelblat 1981) and in 1993 (Bergin and Gibson 1996), are good examples of such works. Here again, an optional assignment on a relevant topic would enrich a class related to software.

The field of computing has a long list of historical contributors such as Leonhard Euler, John von Neumann, and Maurice Wilkes in addition to more contemporary individuals such as Bill Gates, Steve Jobs, Mark Zuckerberg, Larry Page, and Sergey Brin. Whether centuries ago (e.g., Euler), decades ago (e.g., von Neumann), or contemporary pioneers (e.g., Gates), students can become interested in the way their subject evolved over time and how individuals shaped and reshaped the computing field.

Limitations

Embedding history in computing courses often depends on the initiative of the instructor. In general, computing teachers never studied such history in formal settings unless they enrolled in a course through their own initiative. Teachers often need to bootstrap themselves and make some effort to incorporate historical topics in their courses. However, the results derived from such engagement are rewarding, and they often outweigh the cost of the effort involved.

Another limitation in developing modules on computing history is the apparent lack of reliable resources, trained teachers, and institutional support. While the belief for using history to complement computing courses may be strong, institutional support has often been wanting. One reason for this is that history does not usually lead to industrial development or a business presence. Additionally, history is not a topic that normally attracts research grants when compared to other awards given in the IT field.

IFIP and Computing History

In 1960, UNESCO founded the International Federation for Information Processing (IFIP) as a not-for-profit, nongovernmental organization for national computing societies working in the field of information systems. The IFIP organization consists of technical committees (TCs). One such committee (TC 9) addresses the relationship between computers and society. Established in 1976, TC 9 emphasizes the nontechnical aspects of computers on the society, particularly their effect upon people, groups, and institutions. Among other things, TC 9 addresses the use of computers and their effect upon the social consequences, accountability, responsibilities, and the quality of life of humans.

TC 9, as well as other technical committees, operates within a set of working groups (WGs). WG 9.7 on the history of computing is one such working group. IFIP established WG 9.7 in 1992; John A.N. Lee was its founder. The purpose of the working group includes a forum for information exchange in historiography, providing guidance for the implementation of archives, identifying pioneers, promoting “Pioneers Day” at major events, and promoting the history within appropriate curricula. Its activities also provide an impetus to preserve records and artifacts on information processing throughout the world to address the socio-historical context of computing. Its official website (IFIP 2018) reflects the aims and scope of the working group and other related information.

Conclusion

So, why teach computing history? The discussion contained in this entry provides sufficient reason for including computing history within student experiences. The approach suggests that the effect of engaging students in these subjects provides relevance to technical material that includes people, places, and events. Furthermore, history enriches a topic or course. Teachers and students should avail themselves of the many online resources available to them such as virtual

museums, “walk-through” galleries, and oral histories that provide deeper descriptions and understandings of specialized historical events. A resource such as the *IEEE Annals of the History of Computing* (IEEE 2018) contains many formal articles, memoirs, anecdotes, and obituaries; it also provides a foundation for many stories about computing on a global scale.

Using history to teach computing courses is a useful endeavor. The rewards derived from the *teaching* experience offset the preparation and the effort. The rewards derived from the *learning* experience should leave an impression long after students complete a course. Such aspects of engagement add relevance to topics students learn as they prepare themselves for professional careers.

the means to collaboratively develop web content (Alexander 2006).

Wikis add powerful collaborative dimensions to the classroom by actively involving learners in their own construction of knowledge (Boulos et al. 2006). They offer information sharing and collaboration features, acting as cognitive reflection and intensification tools and aiding the construction of meaning through the self-design of knowledge repositories (Jonassen et al. 1999).

Wikis are known for their ease of use and deployment, making both information sharing and straightforward collaboration possible (Boulos et al. 2006). Further, these tools require minimal technical skill to use their features, allowing users to focus on knowledge creation, information exchange, and collaborative tasks without the challenge of a difficult technological environment (Kirkpatrick 2006).

► Social Networking in Higher Education

Wikis as a Collaboration Tool

Kevin R. Parker¹, Joseph T. Chao² and Robert F. Houghton¹

¹Department of Informatics and Computer Science, Idaho State University, Pocatello, ID, USA

²Department of Computer Science, Bowling Green State University, Bowling Green, OH, USA

Definition

A wiki is an interactive, modifiable, and collaborative website, the contents of which can be edited via web browser; only those granted access can modify site content.

Introduction

Wikis are social networking tools characterized by a high degree of connectivity, providing users

Wiki Defined

In essence, a wiki involves a simplified process of creating HTML pages combined with a system to record each individual change that occurs over time, so that at any time a page can revert to any of its previous forms. A wiki may also include tools that allow the user community to monitor changes in the state of the wiki and discuss issues that emerge. While everyone may view a wiki page, some wikis restrict access to a group of approved members, allowing only those members to edit page content. Others allow anyone to both edit and view content (Olson 2006).

Howard “Ward” Cunningham was the first to devise the concept of the wiki. His WikiWikiWeb first became available on the Internet in March 1995 and was so named because Cunningham envisioned a quickly evolving web and remembered that wikiwiki is a Hawaiian word meaning quick. The original site’s URL included the abbreviation “wiki,” and the short form began to be commonly used (Parker and Chao 2008). The word “wiki” is included in the Oxford English Dictionary and is defined as “A type of web page designed so that its content can be edited

by anyone who accesses it, using a simplified markup language” (“wiki, n.”).

A wiki is a collaborative website made up of reader-modifiable web pages. The content of a wiki can be edited by approved members or in some cases anyone visiting the site, allowing them to easily create and edit web pages collaboratively (Chao 2007). Wikis are not just a tool for collaborative authoring but can also serve as a source of information and knowledge. Wikis allow visitors to engage in learning with each other by using wikis as a collaborative environment in which to construct their knowledge, as well as to engage in dialog and share information among participants in group projects (Boulos et al. 2006).

A wiki is essentially a vast collaboration space that allows knowledge to be organized and cross-linked (Leuf and Cunningham 2001). At the functional level, Leuf and Cunningham (2001) describe the essence of wikis as follows:

- A wiki permits users to edit any page or to create new pages within the wiki site, using only a web browser with no additional add-ons.
- A wiki encourages associative thought by making the creation of page links almost intuitively easy, resulting in meaningful topic associations between pages.
- A wiki does not provide a carefully crafted site for casual visitors but rather seeks to involve the visitor in an ongoing process of creation and collaboration that constantly alters the website content.

Some additional features of wikis include the following:

- Wikis are intended to allow multiple users to create knowledge repositories through collaborative authoring.
- Wikis encourage knowledge sharing around topics, which are expected to evolve and often expand into something of a permanent knowledge base.
- Wikis are useful when information is intended to be modified and enhanced through a collaborative effort (Mader 2006c).

Wikipedia, the web-based, open-access encyclopedia, is the largest and most well-known wiki project (Lamb 2004). It is a multilingual, free content encyclopedia written collaboratively by volunteer contributors and provides the foremost illustration of a well-executed wiki. Wikipedia was formally launched in January 2001 and in 2019 the English wikipedia alone had over 5.8 million articles in approximately 300 languages (List of Wikipedias 9). It currently ranks as the fifth most-visited website worldwide (Alexa Internet 2017). The accuracy of encyclopedic entries on scientific topics in Wikipedia is quite good, with the number of errors in a typical Wikipedia entry being only slightly higher than a comparable entry in Encyclopaedia Britannica, often considered the gold-standard entry-level reference work (Giles 2005; Nature editors 2005).

How Wikis Work

Because wikis are web based, navigation is generally intuitive. The processes of reading and editing a wiki are both quite simple. Wikis are editable through a browser: simply clicking an “edit” link allows the user to make instant revisions (Lamb 2004). Wiki content can be linked and cross-linked, making locating and utilizing information quick and easy. Wikis enable users to easily edit or update an existing webpage; as the user browses a topic to which they can intellectually contribute, they can begin editing the page by clicking the appropriate link and making changes from within their browser. There is no fixed taxonomy since the organization of a wiki is based on user contributions and their collective personality (Howley 2007).

Wikis have two types of writing modes: thread mode and document mode. Thread mode permits users to carry out discussions by posting signed messages to which others respond, and eventually a group of threaded messages evolves. Document mode allows users to create collaborative documents. User additions to the wiki document are unsigned, and multiple authors edit and update the content of the document. Over the passage of time, the content becomes a representation of the

shared knowledge or beliefs of all contributors (Leuf and Cunningham 2001).

Wikis provide a mechanism that records every change that occurs over time as a document evolves through a series of revisions. Each time there is a change to a wiki page, that revision of the content becomes the current version, and an older version is archived. Versions of the document can be compared, and edits can be “rolled back” if necessary. Hence, it is possible to revert a page, if necessary, to any of its previous states.

The administrator of the wiki has control over access, determining which portions are user-editable. Some wikis restrict editing access, allowing only approved members to edit page content, while others provide unrestricted access, allowing anyone to both edit and view content (Olson 2006).

Some wiki systems have added functionalities such as web-based spreadsheets, calendars, photo galleries, private workspaces, WYSIWYG editing, and even integration with centralized content management systems (Lamb 2004).

Social Networking Features

Wikis are characterized by a variety of unique and powerful information sharing and collaboration features and therefore epitomize the definition of social networking (Parker and Chao 2007). Wikis are expressly designed for collaborative authoring, allowing topics to be edited directly and encouraging knowledge sharing around topics. The extremely rich, flexible collaborations made possible by wikis have positive psychological consequences for their participants and powerful competitive ones for their organizations (Evans and Wolf 2005).

The information sharing encouraged by wikis allows everyone to take equal responsibility for the information published (Brännström and Mårtensson 2006). The system is democratic because all participants have an equal voice. Anyone can contribute content or modify content contributed by someone else (Korfiatis and Naeve 2005), fostering the social ties vital for knowledge sharing (Boyd 2003; Gonzalez-Reinhart 2005).

This social environment technically supports the aspirations of individuals to belong and contribute in a group atmosphere (Boyd 2003; Gonzalez-Reinhart 2005). Such group participation among volunteers can create social connections that help realize personal goals (Boyd 2003; Gonzalez-Reinhart 2005).

Wikis foster social relationships over a domain of social actions stemming from the acceptance, objection, or rejection of a contribution (Korfiatis and Naeve 2005). The implicit negotiation process involved in writing and structuring an article is of particular interest from a social research perspective. The submission and assessment process involves interactions that characterize the dynamics of the negotiation process (Korfiatis and Naeve 2005). For example, if a user makes a contribution that is not accepted and ultimately rolled back, the user can review the change log to determine whether one or multiple individuals were responsible for the change. They can resubmit their contribution, in either its original or modified form, and continue the negotiation process. The communication, collaboration, and negotiation features make it possible to reach a determination of what is collectively considered acceptable and pertinent knowledge (Gonzalez-Reinhart 2005).

Wikis mimic physical communities through socialization and the exchange of information, leading to the creation of conversational knowledge (Gonzalez-Reinhart 2005). Wiki-style collaborative efforts establish systems of trust and reputation within communities of practice (Evans 2006). A community of practice is made up of people engaged in collective learning in a shared domain, where learning becomes a collaborative process of a group (Brodahl and Hansen 2014). Wikis provide a platform for communities of practice that facilitates the exchange of knowledge (Fuchs-Kittowski et al. 2004), allowing members of the community to share their knowledge with the group, work together, discuss issues, etc. (Schaffert et al. 2006a).

Wikis have a variety of features fundamental to a successful community of practice, including easy participation, a virtual presence, democratic

participation, a variety of interactions, valuable content, connections to a broader subject field, personal and community identity and interaction, and evolution over time (Schwartz et al. 2004). Wikis allow members of a community of practice to discuss concepts and contribute feedback, adapt to situations in which knowledge changes quickly, and provide a convenient means to contribute (Campanini et al. 2004).

Alternative Online Collaboration tools

Wikis are often compared to blogs because they are both characterized by content generation and extremely easy publishing capabilities. They appeared about the same time, and both offer an easy publishing tool for disseminating information as well as getting feedback from the public. Wikis were intended to allow multiple users to create knowledge repositories, while blogs were intended for use by individuals in writing personal diaries.

Although they are intended for different purposes, the distinctions between them are subtle because they have converged in functionality. However, there are a number of noteworthy differences between wikis and blogs, among them being the way they organize their information and the number of contributors and what the contributors intend to achieve (Doyle 2006).

- Wikis are designed for collaborative authoring, while blogs are more personal and generally written by a single author.
- Wikis typically organize information into topics, while blogs organize information in reverse chronological order. Information in blogs is more of a historical record and rarely changes. Topics in wikis are expected to evolve and often expand into a long-term knowledge base.
- The reverse chronological order of blogs makes it difficult to find and browse through all postings on a particular topic. Wikis do not as easily show when information was contributed or in what order, but do show

topic associations and make it easy to browse (Woolf 2006).

- Wiki content is created by allowing the public to edit topics directly, while blog contents belong to the owner but provide a mechanism for reader comments.
- Wikis encourage knowledge sharing around topics, while blogs often share spontaneous thoughts.
- Blogs are more effective for disseminating information and for enabling feedback while keeping the original text intact. Wikis are the preferred tool when information is intended to be modified and enhanced as part of a collaborative effort (Mader 2006c).

Another online tool related to wikis is Google Docs, a web-based text editor that supports collaborative editing (Gruhn and Hannebauer 2012). Like wikis, Google Docs allows users to create and to share online documents, spreadsheets, presentations, and forms and allows concurrent online editing and collaboration for knowledge building by multiple users with minimal technical knowledge of HTML (Chu et al. 2009). Although a variety of studies classify Google Docs as a wiki (West and West 2009; Orehovački and Babić 2017), it is more accurately classified as a “collaborative writing application,” a form of social media that enables the joint and simultaneous editing of a web page or an online document by at least two users (Archambault et al. 2014).

New users cannot edit a system of linked Google Docs. Thus, there are no notable wiki instances using Google Docs as a platform. Further, wikis require additional capabilities over a web-based text editor like Google Docs. Neff (2013) states some reasons why Google Docs does not serve as a suitable wiki, including the fact that Google Docs is optimized for the printed page rather than online viewing, is always in edit mode, has no mechanism to dynamically embed content or lists of documents in another document, does not link documents as easily as wikis but instead requires interaction with menus/mouse and copying full URLs to documents, and lacks cross-document consistent styling.

Additional salient differentiations between wikis and Google Docs are pointed out by Guhlin (2009), including the following:

- Most wikis allow either anonymous editing or editing by a limited number of approved users, while with Google Docs each document is created by an individual who can then invite collaborators.
- A wiki site is a hyperlinked collection of individual pages, while in Google Docs each document is separate.
- Wikis are updated as needed, usually when new information about the topic becomes available, information changes, or a mistake is found. Docs are usually created and edited for a specific purpose, but they can be saved indefinitely for reuse at a later time.

Current State of Wikis in Education

Many educators have embraced wikis since they facilitate not only communication but also the collaborative finding, shaping, and sharing of knowledge, all of which are quintessential in an educational context (Reinhold 2006). Because both teachers and students can easily create wiki pages with no prior knowledge or skill in web development or programming, the extra time necessary to develop these skills is eliminated. The ability to interact with evolving text over time allows teachers and learners to see assignments as they are drafted, rather than reviewing only the final draft. A wiki can also be extremely useful tool both in online classes and even in traditional classes for asynchronous communication within groups. Wikis can be used in education to support a variety of learning paradigms, including cooperative/collaborative learning and reflective learning.

In a cooperative/collaborative learning environment, students participate in heterogeneous groups intended to support the learning of their individual members. Wikis provide an excellent tool for facilitating computer-supported collaborative learning, i.e., the development of collaboration by means of technology to augment

education (Augar et al. 2004). Wikis can also help enhance peer interaction and group work and can facilitate sharing and distributing knowledge and expertise among a cooperative group of learners (Lipponen 2002). Online collaborative tools like wikis can help to alleviate some of the problems inherent in collaborative learning (Houghton et al. 2017), because they share many of the elements fundamental to a community of practice, including an online presence, a variety of interactions, communication, participation, and relationships to a broader subject field of interest (Brodahl and Hansen 2014). These tools can enhance peer interaction and group work, facilitate sharing, and facilitate the distribution of knowledge and information among a community of learners (Lipponen 2002).

Wikis also facilitate reflective learning and enrich students' experience beyond the specific details of each project, "overlayering this experience with a more general and overarching, personally-constructed viewpoint on design processes, on how we experience and create the designed world in which each person lives – and a conceptual framework that will enable them to quickly develop their understanding further" (Chen et al. 2005). The collaborative nature of wikis shifts the focus from individual learners to a larger community.

Wikis in Education

A literature search reveals the application of wikis across a variety of areas. Mader's wikis in education site (2006b) cites such educational uses as simple webpage creation, group authoring, data collection, class/instructor reviews, project development with peer review, and tracking group projects. His online text (Mader 2006a) contains discussions by several authors of such topics as integrating wikis in instruction through group wiki projects, constructing science knowledge, collaborative writing projects, using wikis within course management systems, and wiki-based collaboration and academic publishing. Fountain's (2005) survey of wiki use in education suggests several additional uses of wikis,

such as co-creating and co-monitoring projects and collaborative concept elaboration.

Reviewing some of the uses of wikis in education reveals a great deal of ingenuity and creativity. Duffy and Bruns (2006) list multiple educational uses of wikis:

- Students can use a wiki to develop research projects, with the wiki providing ongoing documentation of their work.
- Students can summarize their thoughts from prescribed readings, using a wiki to compile a collaborative annotated bibliography.
- Course resources like syllabi and handouts can be published via wiki, allowing students to edit and comment for all to see.
- Teachers can construct knowledge bases on wikis, sharing reflections and thoughts regarding teaching practices, supplemented by versioning and documentation.
- Wikis can assist in mapping concepts by documenting brainstorming activities.
- Editing a given wiki topic can produce a linked network of resources.
- Wikis can be used as a presentation tool, allowing students to directly comment on and revise the presentation content.
- Wikis are ideal for group authoring, pulling group members together and enabling them to build and edit the document on a single, central wiki page.

Similarly, Parker and Chao (2007) note additional educational uses for wikis:

- Project planning and documentation
- Facilitating online learning groups
- Semantic wiki to serve as a mathematical resource
- Course textbook writing
- Student software project collaboration

Lamb (2004) suggests that faculty design teams can utilize wikis to quickly and collaboratively build reference lists and outlines, brainstorm instructional strategies, and capture suggestions. Bergin (2002) discusses a variety of uses for wikis including student homepages,

anonymous feedback, student-created FAQs, suggestions related to the course, infrastructure hints, and discussions.

Naish (2006) describes educational uses for wikis including an information resource, a collaboration tool, a tool for building e-learning content, and as icebreaker tools. Schaffert et al. (2006a) suggest the use of wikis in project-based learning, collaborative story writing, and interdisciplinary and intercultural learning.

Rather than discussing specific uses, Tonkin (2005) groups educational wikis into four basic forms:

- Single-user wiki: allows individuals to collect and edit their thoughts using a web-based environment.
- Lab book wiki: allows students to keep notes online but provides the added benefit of allowing them to be peer reviewed and changed by fellow students.
- Collaborative writing wiki: can be used by a team for joint writing.
- Knowledge base wiki: provides a knowledge repository for a group.

Many studies focus on specific educational uses of wikis in the classroom. Leifer (2015) studied the use of a wiki in helping teach pathology, finding that the use of wikis helped the students create presentations, demonstrate time difference in pathology, and find past results quickly. Schelly et al. (2015) used wiki technology to help train students on how to use a 3d printer, employing the wiki as a supplemental manual or textbook to help the students keep track of the nuances of using a 3d printer. Martinsen and Miller (2016) used wikis to help group compositional foreign language assignments to increase student participation in all aspects of the project, rather than just those for which they were specifically responsible. Allen et al. (2015) used a wiki in a chemistry class as a replacement for a college textbook, finding that the students who used the wiki received similar grades and decreased out-of-class study time.

Chen et al. (2015) used wikis to help coordinate lesson plans for science teachers, comparing

the use of wikis and Google Docs. Lawrie et al. (2016) used wikis as a science laboratory notebook. Cunningham et al. (2016) used wikis as a documentation tool to help collect data for a clinical trial, noting that teamwork and collaboration were increased through wiki use as compared to traditional documentation.

Project-Based Learning

Wikis are very effective for project planning and documentation (Schaffert et al. 2006a). Particularly useful in collaborative class projects, wikis make it possible for students to meet virtually at their convenience and work on projects together (Byron 2005). Geographically dispersed project teams can use wikis as a discussion tool, to share ideas and to develop the project. With all comments and ideas consolidated on one webpage, a wiki provides a clearer picture of team direction than do individual email messages (Naish 2006).

Schaffert et al. (2006b) suggest applications of wikis with regard to project knowledge management, including brainstorming and exchange of ideas, coordination of activities, coordination and records of meetings, and providing a virtual notepad for shared information items.

Houghton et al. (2017) and Davey et al. (2016) identify a range of common problems associated with project-based learning and then examine various techniques and tools like wikis to determine their efficacy in helping to overcome those problems. Chen et al. (2005) observed that wikis help to alleviate one of the more common pedagogical challenges associated with project-based courses, that of students seeing what they have produced but not what they have learned.

Conclusion

The use of wikis has proliferated and become more commonplace as insightful educators continue to envision innovative uses. Creative use of wikis and the opportunities for collaboration that they offer have proven beneficial across the educational community. Wikis excel at connecting

students through interaction and collaboration, empowering education through openness and flexibility.

Today's students will not only manage future business innovations but in many cases will drive them. Collaborative creativity is becoming an increasingly critical business skill. Because so many organizations have adopted wikis or other collaborative tools for internal and external collaboration as well as information dissemination, interacting with them at the educational level better prepares students for the workforce. Educational institutions can add immense value to their graduates by familiarizing students with the technologies that make collaborative networks possible. Educators must ensure that graduates are aware of the business contributions made possible by wikis and other social software, not just as a phenomenon but also as a skill (Evans 2006). Educators can more effectively prepare students to make innovative uses of collaborative software tools by incorporating wikis into the curriculum.
